e. Once ATN sets in, ***do not aggressively fluid resuscitate or diurese*** simply to meet UOP goals. Use alternative markers of fluid responsiveness (like blood pressure response to passive straight leg raise) to help determine the need for further fluids and vasopressor medications.

f. Monitor closely for the development of electrolyte disturbances, specifically metabolic acidosis and hyperkalemia. Use medical management of hyperkalemia as appropriate. The JTS CPG on Hyperkalemia and Dialysis in the Deployed Setting describes field-expedient techniques for peritoneal dialysis; however, this should be done in concert with teleconsultation.

Hemodynamics & Monitoring

1) An IV pump is recommended over dial-a-flow and drip-chamber titration (if available).
2) When outdoors, place the monitor, ventilator, and IV pumps upwind and as far away as possible from the patient to minimize contamination of caregivers.
3) Establish arterial line monitoring early when possible for patients with severe COVID-19 disease as they often become hemodynamically unstable.
4) If possible, establish central access early in anticipation of the need for continuous vasopressors. Multiple peripheral IVs may also be needed for infusions of sedatives, analgesia, antibiotics, etc.
5) A conventional central venous catheter can be placed through an introducer catheter (i.e. Cordis) to expand the number of available infusion ports. This should be done during the initial insertion under sterile technique, if possible.
6) Some severely ill COVID-19 patients may develop dilated cardio-myopathy with florid cardiogenic shock. This may be secondary to systemic inflammation, stress, or a direct viral myocarditis. Patients may also develop arrhythmias. Manage arrhythmias following Red Cross advanced life support guidelines.
7) An unexpected change in the vital sign trends or hypotension out of proportion to sedation and PEEP should merit evaluation for additional causes of shock. Limited transthoracic echocardiography may be useful in discriminating between hypovolemic, cardiogenic, and distributive shock (in personnel trained to perform the assessment).
8) Utilize dynamic parameters (i.e. skin temperature, capillary refilling time, pulse pressure variation, blood pressure response to passive straight leg raise, and/or serum lactate measurement) over static parameters to help guide the need for further fluid resuscitation (Surviving Sepsis Campaign COVID-19 Guidelines).
9) Norepinephrine is the first line vasopressor for most causes of shock. Fixed rate vasopressin infusion (0.04 units/min) is useful as an early adjunct in non-cardiogenic shock; start vasopressin when norepinephrine reaches doses above 12mcg/min. Epinephrine is sometimes the only option available in remote locations.
10) Vasopressors should be titrated to a MAP goal of 60- 65 mm Hg. (Surviving Sepsis Campaign COVID-19 Guidelines.)

Continued Care & Prophylaxis

1) Nasogastric or orogastric tube (NG/OGT) should be placed early for gastrointestinal decompression. If medical evacuation is significantly delayed (greater than 24-48 hours), consider starting enteral nutrition.
2) Enteral nutrition is contraindicated in hemodynamically unstable patients (i.e. those on high or increasing doses of vasopressors). Low volume tube feeding on patients with stable low doses of vasopressors is generally safe.
3) At a minimum, confirm position of gastric tube placement with auscultation over both lung fields and the abdomen along with aspiration of gastric contents. Urinalysis test strips for pH may provide an addition method for NG/OGT placement confirmation in patients not on acid suppressive therapy.
4) Goal 25-30 kcal/kg/day + 1-1.2 gm/kg protein; however, this might be difficult, especially in the absence of formal concentrated tube feeds.
5) Meal supplement drinks are not sufficient. For example, one Muscle Milk Light bottle contains only 150 kcal and 28 gm protein in 500 mL, which is extremely dilute compared to most tube feeding formulations. This potentially increase extra-vascular lung water (especially in the setting of critical illness) with minimal benefit to nutritional status.
6) A more concentrated alternative is to use commercially available protein powder (with similar caloric/protein content per scoop) at 1/4 the recommended concentration and mix in a blender until no clumps are visible. Administer in small volume boluses (e.g., 60mL via Toomey syringe) as tolerated every 2 to 4 hours to a goal of 1 gm/kg/day protein content.
7) Further recommendations for enteral nutrition can be found in JTS CPG for Nutritional Support Using Enteral and Parenteral Methods.
8) If possible, blood sugar checks should be obtained at least every 6 hours, particularly for those with known diabetes mellitus.
9) Venous Thromboembolism (VTE) prophylaxis should be given as long as there are no contraindications. Patients with COVID have demonstrated and increase risk of the formation of thrombus formation, therefore it is recommended to administer Lovenox 30 mg SQ twice daily (avoid if evidence of renal failure) or 7,500 units heparin SQ every 8 hours.
10) If pharmacologic prophylaxis is not available, manual ankle plantar/dorsi-flexion range of motion exercises and lower extremity massage every two hours. Consider applying compression stockings if available. DO NOT use ACE wraps.
11) Stress-Ulcer Prophylaxis should be given to all intubated patients as long as there are no contraindications. Famotidine 20 mg IV every 12 hours or 20 mg via NG/OGT twice daily, or consider and a proton pump inhibitor, if available (i.e. pantoprazole 40 mg IV daily or omeprazole via NG/OGT daily).
12) Ventilator Associated Pneumonia prevention bundle applied to the limitations of an austere environment includes:
    - Head-of-bed elevation to 30 degrees
    - Suction the oropharynx as needed
    - Brush teeth every 12 hours, ideally with commercially prepared Chlorhexidine oral care if available.

13) The JTS CPG for Nursing Interventions in Prolonged Field Care provides in-depth discussion of the nursing tasks that may be required if medical evacuation is significantly delayed.

Cardiopulmonary Resuscitation

Cardiopulmonary arrest is a difficult topic. Generally speaking, in cases of cardiac arrest, Cardiopulmonary Resuscitation (CPR) in an austere environment may not be a wise use of resources unless the etiology for the arrest is rapidly reversible. Additionally, significant aerosol generation will invariably occur during CPR of a COVID-19 patient. It is reasonable during a pandemic to establish medical rules of engagement that discourage providers from performing CPR on infected patients. If CPR is performed, efforts should focus on reducing provider exposure to COVID-19 and prioritizing strategies with lower aerosol formation risk. (See DoD Covid-19 PMG.)

Patient Evacuation Considerations for Austere Medicine

Each AOR should develop its own plan for categorizing COVID-19 patients (for the purposes of isolation and evacuation) based on guidance found in DoD policy.

Medical Evacuation

Medical Evacuation using MedCon levels described in Appendix A is one example.

1) Patient movement should be anticipated for COVID-19 PUIs categorized as MedCon 2 or higher. There is no reason to delay notification request for evacuation.
2) Ground and Air Medical Transport will depend on local CASEVAC/MEDEVAC notification plan and CASEVAC/MEDEVAC platforms available for transport.
3) When clinically and operationally feasible and within the provider's scope of practice, obtain central venous access in anticipation of need for multiple infusions, including vasopressors, during transport. Obtain at least two peripheral IV's or one peripheral plus one central line access prior to transport, if possible.
4) Early placement of arterial line for invasive pressure monitoring is recommended, if available.
5) If there is evidence or suspicion for acute coronary syndrome or myocarditis, coordinate the medical management via teleconsultation prior to transport, if possible.
6) Patients requiring >3 Lpm oxygen support to maintain oxygen saturations >93% may not tolerate the hypoxic environment of aeromedical evacuation even with cabin altitude restrictions:
    a. Given concerns surrounding risk associated with procedures done emergently during transport, consider the need endotracheal intubation prior to transport.
    b. The most experienced provider should perform the procedure to secure the airway. Use a video laryngoscope (if available) and rapid sequence induction.
    c. Minimize people in the room during the procedure. Verify all staff have the best available PPE. (See Appendix B.)
    d. Consider consulting the Advanced Critical Care Evacuation Team (ACCET) DSN 312-429-BURN (2876) before transporting patients on moderate to high ventilator settings (PEEP > 14 and FiO_2 > 70%). Refer to JTS CPG for Acute Respiratory Failure.

e. If prone ventilation is to be utilized in-flight, it should be initiated on the ground with adequate time to document patient stability before transport.

7) If intubated, an NG/OGT should be placed pre-flight and attached to intermittent suction.

8) Pre-drawn and pre-mixed medications with primed tubing are examples of time saving measures to be optimized on the patient prior to transport.

9) Prepare patient records for handoff including medical notes, ECGs, laboratory results, and imaging results (if available).

10) Prepare patient belongings and ID/passport to accompany the patient.

11) Place PPE for flight on patient including eye protection and ear protection, and DO NOT forget face covering if not intubated.

Transition of Care for Evacuation

1) Early patient reporting allows the evacuation team to prepare.
   a. The sending facility medical team should provide contact information (if possible).
   b. The evacuation team should contact the sending facility prior to mission (if possible).
2) Handoff to the transport team should include:
   a. Up-to-date COVID-19 testing status (PUI vs confirmed).
   b. Current vital signs, exam findings, and recent trends or changes.
   c. Current medication regimen if initiated (including antibiotics and anticoagulants).
   d. Critical care medication regimen (sedation, analgesia, paralysis, and vasopressors).
   e. Current PPE status, oxygen requirements and ventilator settings.
   f. Any potential COVID-19 related complications identified during management (e.g., heavy respiratory secretions).
3) Upon evacuation team arrival to receive the patient, handoff report should be repeated with key elements above, including any recent patient changes.
4) Transition to the evacuation team monitoring and support equipment will present risk of exposure to healthcare team. In an attempt to mitigate this risk, consider the following:
   a. Personnel should be limited to those directly involved in the care of the patient.
   b. Best available PPE should be worn by everyone involved in the care transition.
   c. ETT clamping technique should be instituted to limit aerosol creation during all ventilator circuit breaks including transfer to evacuation team ventilator.
   d. Sufficient time should be allotted to confirm adequate oxygenation and ventilation prior to departure of the evacuation team.

Establishing a Plan for Telemedicine Consultation

1) Regional Medical Operations Cell should prospectively publish local and regional PACE (Primary-Alternate-Contingency-Emergency) plans for both operational and clinical consultation. Forward-stationed medical teams should test these options PRIOR to needing urgent consultation.

2) Make use of telehealth resources such as the ADVISOR line (866-972-9966, or 833-238-7756), that includes the Virtual Critical Care Consultation (VC3) service. The ADVISOR program is specifically designed for operational virtual health support. Additionally, many VC3 consultants have deployed to remote locations and can help work through the unique problems faced in austere settings. Additional information on ADVISOR can be obtained by emailing dod.advisor_office@mail.mil.

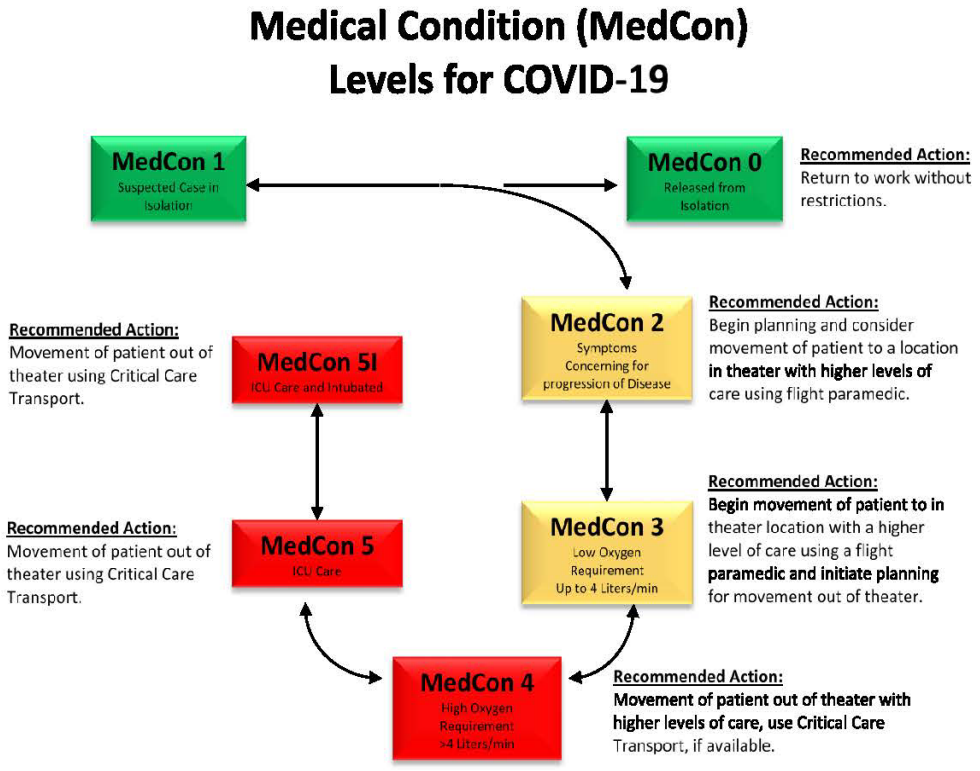
3) Alternatively, contact the following MEDCENs and ask for the on-call critical care staff:

Landstuhl Regional Medical Center, Germany. DSN: 314-590-7141 Intensive Care Unit
Walter Reed National Military Medical Center, MD. (301) 295-4611, option 4 Command Duty or (301) 295-4810 Emergency Room
Madigan Army Medical Center, WA. (253) 968-1110 Information Desk
Brooke Army Medical Center, TX. (210) 916-0808 Emergency Room
Naval Medical Center Portsmouth, VA. (757) 592-5473 Critical Care, (757) 953-1365 Emergency Room
Eisenhower Army Medical Center, GA. (706) 787-6938/6019 AOD or (706) 787-6039 Emergency Room
Travis Air Force Base Medical Center, CA. (707) 423-3040 ICU or (707) 423-3825 Emergency Room
Tripler Army Medical Center, HI. (808) 433-6661 Information Desk or (808) 433-4032 ICU or (808) 433-3707 Emergency Room
William Beaumont Army Medical Center, TX. (915)892-6880 House Supervisor or (915) 742-2139 ICU
Keesler Air Force Base Medical Center, MS. (228) 376-0500 Emergency Room

4) Always be conscious of the need to maintain patient privacy and operational security.

5) Using a standard telemedicine script will improve communications and recommendations for patient management. (See Appendix K.)

Appendix A: Medical Condition Levels



Medical Condition (MedCon) Levels for COVID-19
MedCon 1
Suspected Case in Isolation
MedCon 0
Released from Isolation
Recommended Action:
Return to work without restrictions.
MedCon 2
Symptoms Concerning for progression of Disease
Recommended Action:
Begin planning and consider movement of patient to a location in theater with higher levels of care using flight paramedic.
Recommended Action:
Movement of patient out of theater using Critical Care Transport.
MedCon 5I
ICU Care and Intubated
Recommended Action:
Movement of patient out of theater using Critical Care Transport.
MedCon 5
ICU Care
MedCon 3
Low Oxygen Requirement Up to 4 Liters/min
Recommended Action:
Begin movement of patient to in theater location with a higher level of care using a flight paramedic and initiate planning for movement out of theater.
MedCon 4
High Oxygen Requirement >4 Liters/min
Recommended Action:
Movement of patient out of theater with higher levels of care, use Critical Care Transport, if available.

Intent and Implications on Evacuation:

MedCon 1: Mild flu-like symptoms, SpO2 >94% on room air, hemodynamically normal. Overall, there is low likelihood of these patients significantly worsening in the next 24-48hrs. These patients may not need evacuation to higher level of care.

MedCon 2: Progressive symptoms that are concerning based upon provider clinical judgement. This is an "early warning" phase to prepare to evacuate.

MedCon 3: Requiring supplemental O2 to maintain SpO2 >92% at flow rates *not* significantly exceeding oxygen condenser capabilities (i.e. SAROS). While these patents may not necessarily exceed local capabilities, they represent a population at risk of rapid decompensation in the next 24-48hrs.

MedCon 4: Requiring supplemental O2 to maintain SpO2 >92% at flow rates *beyond* condenser capabilities (i.e. need to use D-cylinder oxygen support). These patients exceed the local capabilities for prolonged care of a patient in respiratory failure and/or will deplete oxygen supplies in less than 24 hours. These patients represent a high risk for hemodynamic deterioration and/or emerging requirement for mechanical ventilation.

MedCon 5: Patients requiring advanced airway management up to and including definitive airway placement and/or with continued hemodynamic instability. These patients need urgent medical evacuation with critical care support to Role 3 or higher facilities.

Appendix B: Continued…

Mask Guidance

SURGICAL MASKS

DISCARD MASK IF:

- Contaminated with blood, respiratory or nasal secretions, or other bodily fluids from patients.
- Obviously damaged or hard to breathe through.
- At the conclusion of your shift.

EXTENDED USE:

- Wear mask for ENTIRE shift unless soiled, damaged, or hard to breathe through.
- Do not touch the mask. If you touch or adjust your mask, you must immediately perform proper hand hygiene.
- Leave the patient care area if you need to remove your mask.
- Consider use of a face shield over mask.

REUSE:

- Masks that fasten via ties that are unable to be undone and are torn need to be discarded.
- Masks should be carefully folded so the outer surface is held inward and against itself to reduce contact with the outer surface during storage.
- Keep used masks in a clean, breathable container such as a paper bag between uses. Do not store in a plastic bag. Keep in a clean space outside patient room, such as a wall locker next to patient room or top of the isolation cart. To prevent accidental use of another's mask, label the container:
  - First initial and last name of owner
  - Strap of mask with first initial and last name of owner

Glossary

Extended Use — The practice of wearing the same mask/respirator for repeated close contact encounters with several patients, without removing the mask/respirator between patient encounters.

Reuse — The practice of using the same mask/respirator for multiple encounters with several patients but removing it after each encounter.

N95 RESPIRATORS

Extended and limited reuse of respirators were recommended for conserving respirators during previous respiratory pathogen outbreaks and pandemics.

Use face shield over N95 respirator to reduce surface contamination.

Perform hand hygiene with soap and water or an alcohol-based hand sanitizer before and after touching or adjusting respirator.

DISCARD N95 RESPIRATOR IF:

- Used for aerosol-generating procedure.
- Contaminated with blood, respiratory or nasal secretions, or other bodily fluids from patients.
- Obviously damaged or hard to breathe through.
- Reused (donned/doffed) a maximum of five times.

EXTENDED USE:

Extended use may be implemented when multiple patients are infected with the same respiratory pathogen and patients are placed together in dedicated waiting rooms or hospital wards.

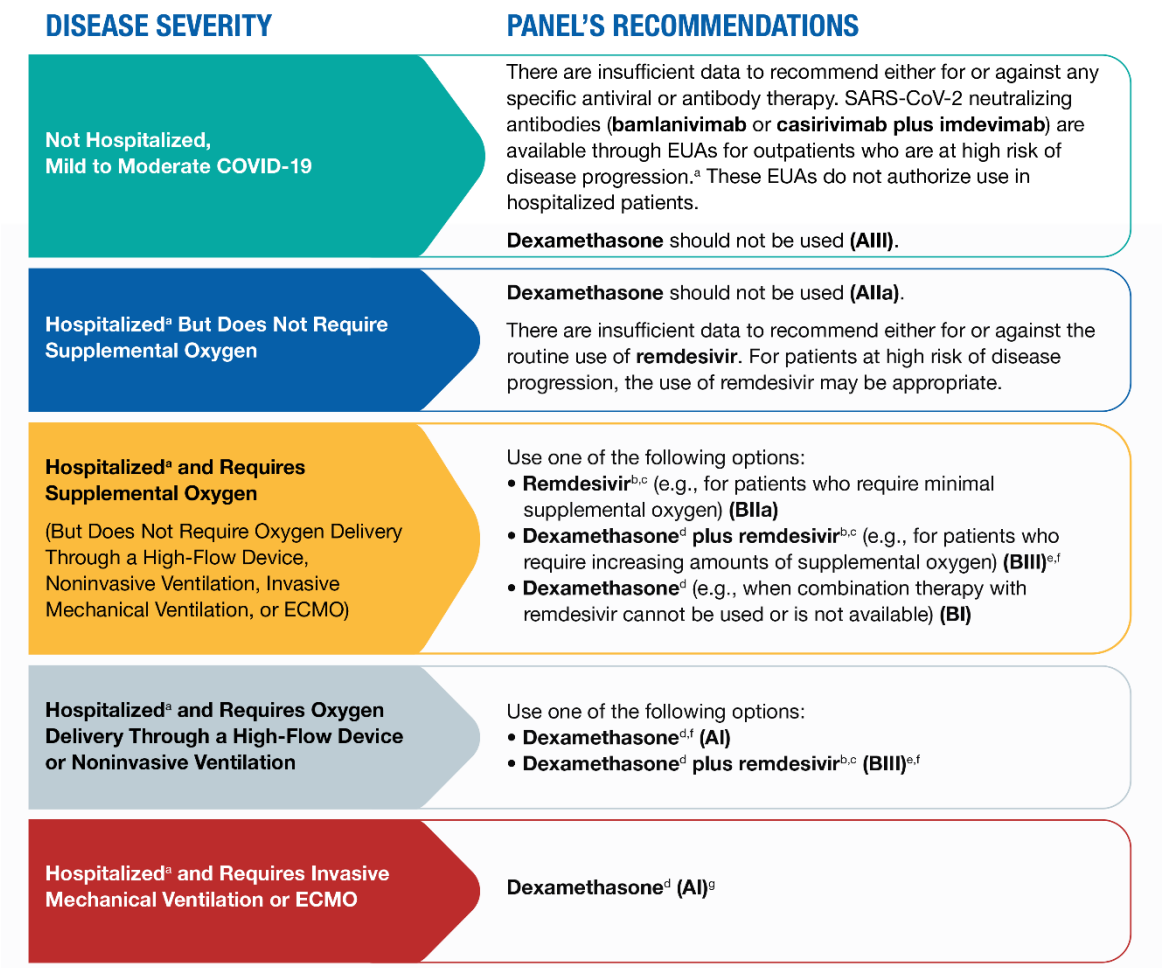
REUSE:

- Keep used respirators in a clean, breathable container such as a paper bag between uses. Do not store in a plastic bag. Keep in a clean space outside patient room such as a wall locker near patient's room or top of the isolation cart. To prevent accidental use of another person's respirator, label the container:
  - First initial and last name of owner
  - Strap of respirator with first initial and last name of owner
- Avoid touching the inside of the respirator. If inadvertent contact with the inside of the respirator, perform hand hygiene as described above.
- Use a pair of clean (non-sterile) gloves when donning a used N95 respirator and performing a user seal check. Discard gloves after the N95 respirator is donned and any adjustments are made to ensure the respirator is sitting comfortably on your face with a good seal.

Appendix C: Pharmacologic Management of Patients with COVID-19 Based on Disease Severity

Figure 1. Pharmacologic Management of Patients with COVID-19 Based on Disease Severity

Doses and durations are listed in the footnote.



DISEASE SEVERITY
PANEL'S RECOMMENDATIONS
Not Hospitalized, Mild to Moderate COVID-19
There are insufficient data to recommend either for or against any specific antiviral or antibody therapy. SARS-CoV-2 neutralizing antibodies (bamlanivimab or casirivimab plus imdevimab) are available through EUAs for outpatients who are at high risk of disease progression.[a] These EUAs do not authorize use in hospitalized patients.
Dexamethasone should not be used (AIII).
Hospitalized[a] But Does Not Require Supplemental Oxygen
Dexamethasone should not be used (AIIa).
There are insufficient data to recommend either for or against the routine use of remdesivir. For patients at high risk of disease progression, the use of remdesivir may be appropriate.
Hospitalized[a] and Requires Supplemental Oxygen
(But Does Not Require Oxygen Delivery Through a High-Flow Device, Noninvasive Ventilation, Invasive Mechanical Ventilation, or ECMO)
Use one of the following options:
• Remdesivir[b,c] (e.g., for patients who require minimal supplemental oxygen) (BIIa)
• Dexamethasone[d] plus remdesivir[b,c] (e.g., for patients who require increasing amounts of supplemental oxygen) (BIII)[e,f]
• Dexamethasone[d] (e.g., when combination therapy with remdesivir cannot be used or is not available) (BI)
Hospitalized[a] and Requires Oxygen Delivery Through a High-Flow Device or Noninvasive Ventilation
Use one of the following options:
• Dexamethasone[d,f] (AI)
• Dexamethasone[d] plus remdesivir[b,c] (BIII)[e,f]
Hospitalized[a] and Requires Invasive Mechanical Ventilation or ECMO
Dexamethasone[d] (AI)[g]
Rating of Recommendations: A = Strong; B = Moderate; C = Optional
Rating of Evidence: I = One or more randomized trials without major limitations; IIa = Other randomized trials or subgroup analyses of randomized trials; IIb = Nonrandomized trials or observational cohort studies; III = Expert opinion

[a] See the Panel's statements on the FDA EUAs for bamlanivimab and casirivimab plus imdevimab. These EUAs do not authorize use in hospitalized patients.

[b] The remdesivir dose is 200 mg IV for one dose, followed by 100 mg IV once daily for 4 days or until hospital discharge (unless the patient is in a health care setting that can provide acute care that is similar to inpatient hospital care). Treatment duration may be extended to up to 10 days if there is no substantial clinical improvement by Day 5.

[c] For patients who are receiving remdesivir but progress to requiring oxygen through a high-flow device, noninvasive ventilation, invasive mechanical ventilation, or ECMO, remdesivir should be continued until the treatment course is completed.

[d] The dexamethasone dose is 6 mg IV or PO once daily for 10 days or until hospital discharge. If dexamethasone is not available, equivalent doses of other corticosteroids, such as prednisone, methylprednisolone, or hydrocortisone, may be used. See the Corticosteroids section for more information.

[e] The combination of dexamethasone and remdesivir has not been studied in clinical trials.

[f] In the rare circumstances where corticosteroids cannot be used, baricitinib plus remdesivir can be used **(BIIa)**. The FDA has issued an EUA for baricitinib use in combination with remdesivir. The dose for baricitinib is 4 mg PO once daily for 14 days or until hospital discharge.

[g] The combination of dexamethasone and remdesivir may be considered for patients who have recently been intubated **(CIII)**. Remdesivir alone **is not recommended**.

Key: ECMO = extracorporeal membrane oxygenation; EUA = Emergency Use Authorization; FDA = Food and Drug Administration; IV = intravenous; the Panel = the COVID-19 Treatment Guidelines Panel; PO = orally; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2

Appendix D: Intravenous Medication Drips (Courtesy SMOG CY20)

KETAMINE (KETALAR)

Dosing Range: 15-50mcg/kg/min

Appendix E ARDSNET Protocol (Courtesy ARDSnet CY08)

NIH NHLBI ARDS Clinical Network
Mechanical Ventilation Protocol Summary

INCLUSION CRITERIA: Acute onset of

1. $PaO_2/FiO_2 \leq 300$ (corrected for altitude)
2. Bilateral (patchy, diffuse, or homogeneous) infiltrates consistent with pulmonary edema
3. No clinical evidence of left atrial hypertension

PART I: VENTILATOR SETUP AND ADJUSTMENT

1. Calculate predicted body weight (PBW)
   Males = 50 + 2.3 [height (inches) - 60]
   Females = 45.5 + 2.3 [height (inches) -60]
2. Select any ventilator mode
3. Set ventilator settings to achieve initial V_T = 8 ml/kg PBW
4. Reduce V_T by 1 ml/kg at intervals ≤ 2 hours until V_T = 6ml/kg PBW.
5. Set initial rate to approximate baseline minute ventilation (not > 35 bpm).
6. Adjust V_T and RR to achieve pH and plateau pressure goals below.

---

pH GOAL: 7.30-7.45

Acidosis Management: (pH < 7.30)

If pH 7.15-7.30: Increase RR until pH > 7.30 or $PaCO_2$ < 25 (Maximum set RR = 35).

If pH < 7.15: Increase RR to 35.
If pH remains < 7.15, V_T may be increased in 1 ml/kg steps until pH > 7.15 (Pplat target of 30 may be exceeded).
May give $NaHCO_3$

Alkalosis Management: (pH > 7.45) Decrease vent rate if possible.

I: E RATIO GOAL: Recommend that duration of inspiration be ≤ duration of expiration.

PART II: WEANING

A. Conduct a SPONTANEOUS BREATHING TRIAL daily when:

1. $FiO_2 \leq 0.40$ and PEEP ≤ 8 OR $FiO_2 \leq 0.50$ and PEEP ≤ 5.
2. PEEP and FiO_2 ≤ values of previous day.
3. Patient has acceptable spontaneous breathing efforts. (May decrease vent rate by 50% for 5 minutes to detect effort.)
4. Systolic BP ≥ 90 mmHg without vasopressor support.
5. No neuromuscular blocking agents or blockade.

OXYGENATION GOAL: PaO_2 55-80 mmHg or SpO_2 88-95%
Use a minimum PEEP of 5 cm H_2O. Consider use of incremental FiO_2/PEEP combinations such as shown below (not required) to achieve goal.

Lower PEEP/ higher FiO2

FiO_2	0.3	0.4	0.4	0.5	0.5	0.6	0.7	0.7
PEEP	5	5	8	8	10	10	10	12

FiO_2	0.7	0.8	0.9	0.9	0.9	1.0
PEEP	14	14	14	16	18	18-24

Higher PEEP/ lower FiO2

FiO_2	0.3	0.3	0.3	0.3	0.3	0.4	0.4	0.5
PEEP	5	8	10	12	14	14	16	16

FiO_2	0.5	0.5-0.8	0.8	0.9	1.0	1.0
PEEP	18	20	22	22	22	24

PLATEAU PRESSURE GOAL: ≤ 30 cm H_2O
Check Pplat (0.5 second inspiratory pause), at least q 4h and after each change in PEEP or V_T.
If Pplat > 30 cm H_2O: decrease V_T by 1ml/kg steps (minimum = 4 ml/kg).
If Pplat < 25 cm H_2O and V_T< 6 ml/ kg, increase V_T by 1 ml/kg until Pplat > 25 cm H_2O or V_T = 6 ml/kg.
If Pplat < 30 and breath stacking or dys-synchrony occurs: may increase V_T in 1ml/kg increments to 7 or 8 ml/kg if Pplat remains ≤ 30 cm H_2O.

B. SPONTANEOUS BREATHING TRIAL (SBT):
If all above criteria are met and subject has been in the study for at least 12 hours, initiate a trial of UP TO 120 minutes of spontaneous breathing with FiO2 ≤ 0.5 and PEEP ≤ 5:

1. Place on T-piece, trach collar, or CPAP ≤ 5 cm H_2O with PS ≤ 5
2. Assess for tolerance as below for up to two hours.
   a. $SpO_2 \geq 90$: and/or $PaO_2 \geq 60$ mmHg
   b. Spontaneous $V_T \geq 4$ ml/kg PBW
   c. RR ≤ 35/min
   d. pH ≥ 7.3
   e. No respiratory distress (distress= 2 or more)
      - HR > 120% of baseline
      - Marked accessory muscle use
      - Abdominal paradox
      - Diaphoresis
      - Marked dyspnea
3. If tolerated for at least 30 minutes, consider extubation.
4. If not tolerated resume pre-weaning settings.

Definition of UNASSISTED BREATHING
(Different from the spontaneous breathing criteria as PS is not allowed)

1. Extubated with face mask, nasal prong oxygen, or room air, OR
2. T-tube breathing, OR
3. Tracheostomy mask breathing, OR
4. CPAP less than or equal to 5 cm H_20 **without pressure support or IMV assistance.**

Appendix F: Oxygen Generator Guide

Medical Oxygen Generator (MOG)

Otherwise known as Expeditionary Deployable Oxygen Concentrator System (EDOCS). EDOCS is designed to provide 120Lpm of 93 percent oxygen and medical grade compressed air for patients, anesthesia machines, and mechanical ventilators. It can also be used to fill high pressure oxygen cylinders up to 2250 psig.

Fills cylinders to 2250 PSIG using M Cylinder Charging Station:

- "H" (6000 L) Cylinder 4.5 Minutes
- "D" (370 L) Cylinder 4x 60 Minutes
- "E" (620 L) Cylinder 4x 60 Minutes

Portable Oxygen Generator System (POGS)

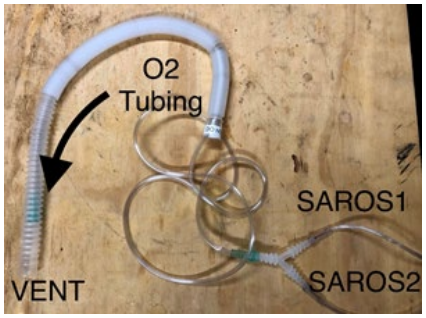
The Portable Oxygen Generation System (POGS 33) is designed to provide 33Lpm of 93 percent oxygen and medical grade compressed air for patients, anesthesia machines, and mechanical ventilators. It can also be used to fill high pressure oxygen cylinders up to 2200 psig.

Fills cylinders to 2200 PSIG with Micro Boost / HV Booster:

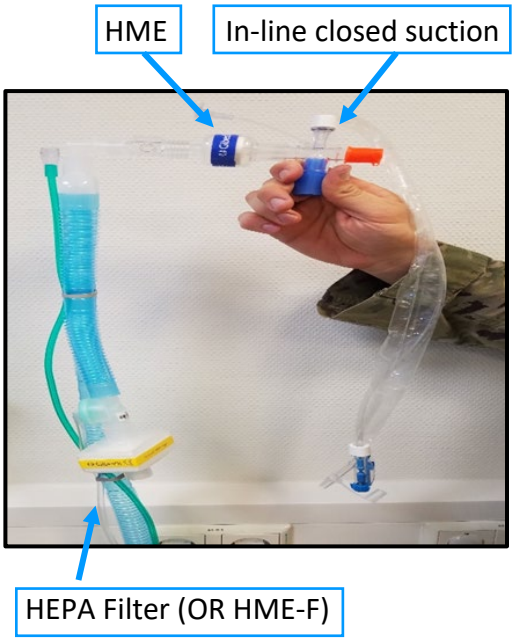
- "H" (6000 L) Cylinder not possible / 3 Hours with HV Booster
- "D" (370 L) Cylinder 52 Minutes / 12 Minutes with HV Booster
- "E" (620 L) Cylinder 1.5 Hours / 19 Minutes with HV Booster

Oxygen Generator Field Portable (OGFP)

Otherwise known as SAROSTM Oxygen System. OGFP is a small, battery operated oxygen concentrator used to provide low flow (up to 3Lpm) of continuous oxygen support for combat casualties. The oxygen support can be increased by filling an oxygen reservoir using two devices (as pictured below).



Appendix G: EMV+ 731 Ventilator Set-Up Guide



*For austere set-up the, simply inserting one HME-F filter between the ETT and ventilator tubing circuit is good enough. (See Appendix H.)

Recommended Items:

Tubing: Circuit Vent Single Limb WYE Adult/Pedi 1S
MFG: Zoll Medical MFG CAT #: 820-0106-00

Closed In Line Suction: In Line Suction 20S 12F
MFG: Smith Medical/Meditrade MFG CAT #: Z210-12

Heat Moisture Exchange: Humid-Vent 2S up to 1500ML
MFG: TELEFLEX MFG REF #: 14412

End Tidal CO_2 Adapter: Adapter Airway Disposable Zoll
MFG: Zoll Medical MFG CAT #: 8000-0260-01

Oxygen Hose: Hose ASB Cond 6FT OXY DIS HEX NUT
MFG: AMVEX MFG REF #: HS06ODFDF

HEPA Filter: ISO-GARD HEPA Light Filter (Machine)
MFG: Teleflex MFG REF #: 28022

OR

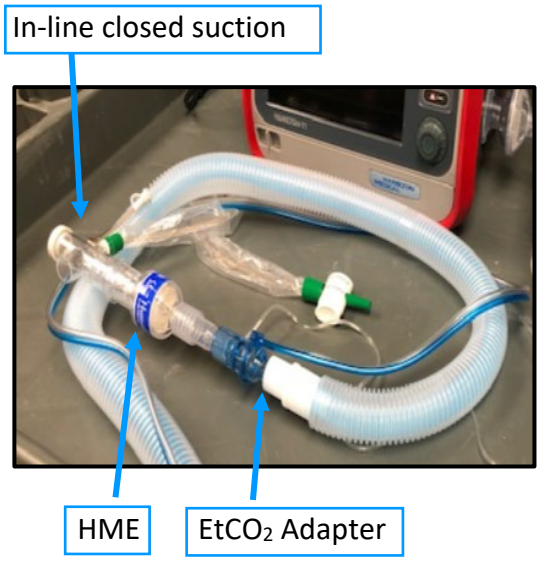
HME-F: Filter Humid-Vent Compact up to 1000ML
MFG: Teleflex MFG REF #: 19402

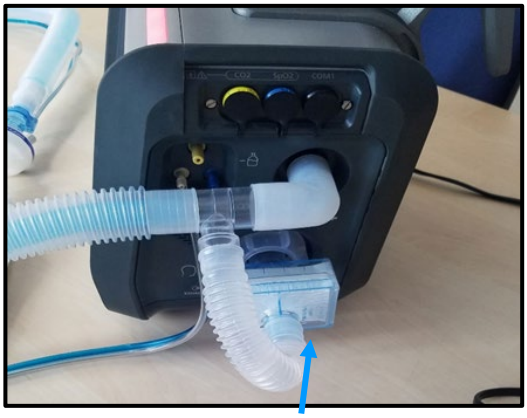
Order of Assembly:
ETT>>In-Line Suction>>HME>>End-Tidal CO_2 Adapter>>Tubing>>Ventilator

Additional Considerations:

1. Reference JTS Acute Respiratory Failure CPG for initial settings and ARDSnet protocol card for adjustment.
2. ETT should be temporarily clamped with a padded hemostat during any circuit break.
3. HME (or HME-F) should be placed in the inspiratory limb to humidify gas delivered to patient.
4. HEPA filter (or HME-F) should be placed at the end of the expiratory limb to minimize viral aerosol.
5. HEPA filter (or HME-F) should be placed in the air inlet to mitigate device contamination.
6. A BVM connected to oxygen supply with viral filter and PEEP valve should always be available!
7. Oxygen hose should be connected directly to 50psi oxygen source (e.g., D-cylinder), NOT to a flow meter!

Appendix H: Hamilton T1 Set-Up Guide





** For austere set-up the, simply inserting one HME-F filter between the ETT and ventilator tubing circuit is good enough (see Appendix I)*

Recommended Items:

Tubing: Breathing Circuit Set, COAXIAL
MFG: Hamilton PART #: 260240

Closed In Line Suction: In Line Suction 20S 12F
MFG: Smith Medical/Meditrade MFG CAT #: Z210-12

Heat Moisture Exchange: Humid-Vent 2S UP TO 1500ML
MFG: Teleflex MFG REF #: 14412

End Tidal CO2 Adapter: Adapter Airway Disposable Zoll
MFG: Zoll Medical MFG CAT #: 8000-0260-01

Oxygen Hose: Hose ASB Cond 6FT OXY DIS HEX NUT
MFG: AMVEX MFG REF #: HS06ODFDF

HEPA Filter: ISO-GARD HEPA Light Filter (Machine)
MFG: Teleflex MFG REF #: 28022

OR

HME-F: Filter Humid-Vent Compact up to 1000ML
MFG: Teleflex MFG REF #: 19402

Order of Assembly:
ETT>>In-Line Suction>>HME>>End-Tidal CO_2 Adapter>>Tubing>>Ventilator

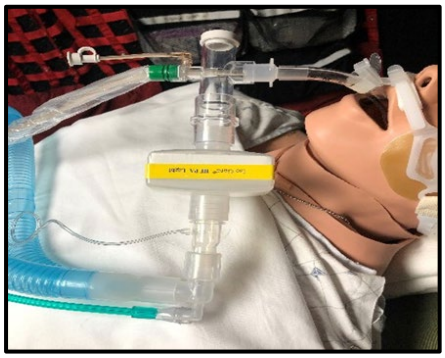
Additional Considerations:

1. Reference JTS Acute Respiratory Failure CPG for initial settings and ARDSnet protocol card for adjustment.
2. The mode should be set at "(S)CMV+"
3. ETT should be temporarily clamped with a padded hemostat during any circuit break.
4. HME (or HME-F) should be placed in the inspiratory limb to humidify gas delivered to patient.
5. HEPA filter (or HME-F) should be placed at the end of the expiratory limb to minimize viral aerosol.
6. A BVM connected to oxygen supply with viral filter and PEEP valve should always be available!
7. Oxygen hose should be connected directly to 50psi oxygen source (e.g., D-cylinder), NOT to a flow meter!

Appendix I: BVM and SAVe II Set-Up Guide

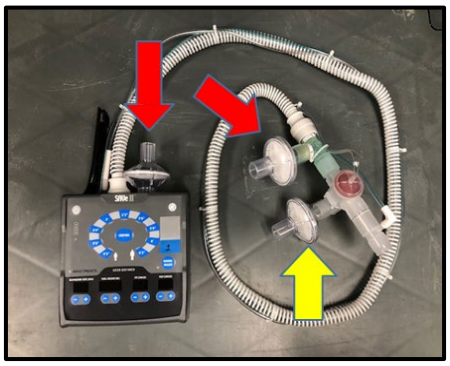
For Bag-Valve Mask Ventilation (BMV):

ETT (or Mask)>>HEPA (of HME-F)>>End-Tidal CO_2 Adapter (optional)>> AMBU Bag (with PEEP valve)
*Microorganism filters minimize viral aerosol formation
**PEEP valves are critical supply for acute lung injury
***End-Tidal CO_2 adapter is optional



For Circuit using only one HME-F:

ETT>>In-Line Suction>>HEPA (or HME-F)>>End-Tidal CO_2 Adapter (optional)>>Tubing>>Ventilator
*HME will NOT minimize viral aerosol formation
**Must be HEPA or HME-F microorganism filter
***End-Tidal CO_2 adapter is optional



For SAVe II Ventilator Set-up:

For the SAVe II ventilator, 3 filters are necessary. The red arrows mark where room air is entrained into the circuit. The yellow arrow shows the exhalation valve.
*Manufacturer does not recommend using this device in contaminated environments
**The debris filter is designed to stop particulates, not chemical or biological agents
***End-Tidal CO_2 adapter is optional

Appendix J: Preparation for Transport Checklist (courtesy SMOG CY20)

PRE-FLIGHT CHECKLIST

(for Critical Care and Post-Surgical Transfers)

Once the decision is made to transfer a patient and an accepting physician has been obtained, the following steps will be taken to prepare the patient for transport:

Initials	Evaluation Steps
	1. Sending location/physician: _____Accepting location/physician:_____ Flight nurse called: name / time: _____
	2. Anesthesia called: intubation if indicated. ETT secured/marked
	3. Patient meets criteria for en route critical care transport: risk documented by sending physician (POST-OPERATIVE and CC INTRAFACILITY TRANSFER, Pre-Transfer Patient Status Requirements)
	Preparation Steps
	Positioning and Proper Monitoring:
	1. Patient moved to litter (collapsible handles), positioned, padded, strapped, equipment (with necessary attachments) added and secured.
	2. For head-injured patients, a pre-sedation neurologic examination will be performed. GCS and neurological exam documented on the en route care form, suggest placing patient sitting at 30°-45°.(For eye injured patients, fox shield in place. For burn patients, JTS burn sheet initiated.)
	3. Ventilator switched to PMI vent at least 20-30 min prior to flight and set with transfer settings ordered by physician.
	4. IV / IO access verified, patent, and secured.
	5. Arterial line inserted and secured, if indicated. Transducer accessible.
	6. Ventilator tubing checked to be free from obstruction, with $ETCO_2$ and secondary lines attached.
	7. Orogastric or nasogastric tube is inserted (unless contraindicated), placement verified with chest x-ray, and attached to low-intermittent suction.
	8. Chest tubes to water seal/suction (place Heimlich valve for non-atrium chest drainage systems).
	9. Wound vacuum disconnected and stowed.
	10. Foley catheter secured, urine output measured and documented.
	Equipment, Medication, Chart, and Personnel Preparation:
	11. Medications needed for flight prepared and organized.
	12. Flight equipment bag obtained and checked. Backup pulse oximeter readily available.
	13. Complete chart photocopied (including x-ray cd), patient belongings bagged and tagged. Transfer Document, or other theater / unit approved transfer document, has been initiated.
	14. Earplugs and eye protection for patient and flight nurse.
	15. If facility sends medical attendant, attendant must have relevant personal protective equipment. In a combat environment this includes: Uniform, Kevlar, IBA, Weapon, ID Card, and equipment for transport.
	Ventilator Management:
	16. Blood gas (preferably ABG) obtained, 15 min after initial settings and ventilator changes. All efforts will be made to have a documented blood gas within 30 minutes prior to flight time.
	17. Adjust ventilator settings and check O_2 tank for length of flight. Resuscitator bag under patient's head with tubing connected to O_2 source, vent tubing free from obstruction.
	Final Verification:
	18. Transferring Physician, Flight Paramedic, ECCN (or Flight Provider) verbally agrees to flight care plan.
	19. Critical Care Transfer Orders reviewed and signed by transferring physician.(STANDARD ORDER SET for CRITICAL CARE TRANSFERS)
	20. Enroute CC Transfer Document with completed preflight and enroute care data handed over to and confirmed by receiving provider / facility.

Appendix L: Minimum, Better, Best - Equipment and Supplies

Problem	Minimum	Better	Best
PPE	See Appendix on PPE, varies with intensity of exposure		
Testing	Malaria Rapid Diagnostic Testing (in endemic areas)	Plus: Ultrasound device 12-Lead ECG Influenza & Dengue Rapid Tests POCT Blood Gas POCT Glucometer	Above plus: Chest X-Ray COVID-19 PCR Testing Respiratory Pathogen Film Array Other testing per DOD COVID PMG Other clinically indicated testing
Oxygen Supply	Oxygen Generator Field Portable (SAROS™)[a]	Plus: Compressed oxygen cylinders	Plus: Oxygen Generating System
Ventilator	Bag-Valve-Mask Ventilation with PEEP valve, HEPA Filter (or HME-F), and oxygen supply	Rescue Ventilator (SAVe II)	Transport Ventilator (EMV+ 731 or Hamilton T1)
In-line Filter Placement (Appendices E, F, G)	HME-F (or HEPA Filter) at Y-Piece between ETT and ventilator tubing	Plus: HME/HME-F at Y-Piece and HEPA Filter in exhalation limb	Plus: In-line Heated Humidification Device (i.e. Hamilton H900)
Monitoring	Pulse Oximeter, Manual BP Cuff, Physical Exam Document trends using PFC Flowsheet or similar	Plus: End-Tidal Capnometry	Plus: Continuous cardiac monitoring Invasive arterial pressure monitoring
IV Drips	Drop counting (Drip Chamber)	In-line Dial-A-Flow device	IV Pump
Medications	Ketamine Midazolam Acetaminophen Ertapenem[b]	Plus: Etomidate Vecuronium Fentanyl Epinephrine Ceftriaxone Azithromycin Ondansetron	Plus: Desmedetomidine Propofol Norepinephrine Rocuronium Levofloxacin IV Glucocorticoid[c] Vasopressin
Airway	Laryngeal Mask Airway (Cricothyroidotomy for emergent cases)	Direct Laryngoscopy	Video Laryngoscopy
Secretion Management (not including HMEs)	Positioning Chest Percussion Bulb Suction	Plus: Bronchodilators 3% Saline[d] Suction device	Plus: N-Acetylcystine[d] Consider anti-sialagogues[e]
VTE Prophylaxis	Ambulation[f]	Range of Motion Exercises Extremity Massage	Low Molecular Weight Heparin or Unfractionated Heparin

a - While compressed gas cylinders are more widely fielded than OGFP/SAROS systems, the prolonged need for oxygen requires an emphasis on being able to supply O_2 for a prolonged period of time.
b - Ertapenem is a widely fielded broad spectrum antibiotic with adequate activity against common organisms causing community acquired pneumonia. Ertapenem is not necessary (for CAP) if antibiotics specific for CAP are available.
c - Methylprednisolone (Solu-medrol), Hydrocortisone (Solu-cortef), or Dexamethasone.
d - Require pre-treatment with a bronchodilator to avoid bronchospasm.
e - Anti-sialagogues are of uncertain benefit; consider telehealth consultation before use.
f - Patients that are able to ambulate or at least perform bedside exercises are encouraged to do so. Non-graduated compression stockings or circumferential ACE wraps are NOT encouraged given risk for venous compression and stasis with higher risk for thrombosis.

Appendix M: Example Equipment Checklists

Durable Equipment Kept On Standby		
□ Litter Stanchions (or fabricated stands)	□ Power Strips / Extension cord	□ Hemodynamic Monitoring Equipment
□ NATO or Talon Litter	□ EMV+ 731 (or Hamilton T1) with charger	□ Infusion Pumps with extra battery and charging cable
□ Mattress pad, inflatable sleeping pad, or Warrior Evacuation Litter Pad	□ Portable Suction Unit with charger	□ Ultrasound with phased array and linear probes
□ 3x blankets or large pillows for offloading pressure points	□ D-Cylinder(s) with regulator, wrench, and high pressure tubing	□ Video-laryngoscope (e.g., GlideScope) and rigid intubating stylet
□ 550 Cord for hanging drips	□ Oxygen Generator Field Portable (i.e. SAROS) with charger	□ i-STAT with several cartridges

Intubation & Ventilator Kit		
□ Bag-Valve Mask	□ GlideScope Sheath, Size 4	□ Tube Securement (e.g. Hollister AnchorFast, Thomas Tube Holder)
□ Non-Rebreather Mask	□ GlideScope Sheath, Size 3	□ Yankauer with Suction Tubing
□ HME-Filter (1x for BVM, 1x for Vent)	□ GlideScope Stylet	□ 18fr Salem Sump NG/OGT
□ Color-Capnometer OR $EtCO_2$ monitor adapter	□ Direct Laryngoscope handle with batteries	□ 60mL Toomey Syringe
□ ETT, 7.0mm ID	□ Macintosh DL blade, size 3 or 4	□ Large Hemostat for clamping ETT
□ ETT, 8.0mm ID	□ Miller DL blade, size 2	□ In-line suction adapter
□ 10mL Syringe	□ Flexible Stylet	□ Ventilator Tubing
□ Airway Introducer (a.k.a. Bougie)	□ LMA, iGel size 4 OR standard LMA	
□ Cricothyroidotomy Kit	□ Tongue Depressor	

Central Line Placement Kit (if within scope of practice)	
□ Appropriately sized surgical gloves	□ 1x Clear Occlusive Dressing (i.e. Tegaderm)
□ 2x ChloraPrep or Povidone-Iodine swabs	□ 1x Cordis Introducer Catheter Kit
□ 1x Needleless Port (a.k.a. Posi-Flow Valves)	□ 1x Surgical Drape (if not included in kit)

Arterial Line Placement Kit (if within scope of practice)		
□ Appropriately sized surgical gloves	□ 1x Straight Needle with 2-0 Silk Suture	□ 1x VAMP Pressure Transducing Tubing
□ 2x ChloraPrep or Povidone-Iodine swabs	□ 2x 4x4 Gauze Packets	□ 1x Pressure Bag (500mL)
□ 2x ARROW Radial Arterial Line 'Dart'	□ 1x Clear Occlusive Dressing (i.e. Tegaderm)	□ 1x 500mL Normal Saline

Medication Administration Kit		
□ 4x Peripheral IV Start Kit*	□ 2x 500mL Normal Saline (carrier fluid)	□ 10x 10mL Syringes
□ 4x Primary IV Tubing, 10gt	□ 2x 250mL Normal Saline (for drips)	□ 10x 5mL Syringes
□ 20x Alcohol Swabs	□ 4x 100mL Normal Saline (for drips)	□ 20x 10mL Saline Flush
□ 1x 1" Tape Roll	□ 2x 1000mL Lactated Ringers (for bolus)	□ 20x 18g Needles

Additional Equipment (Foley, Pneumothorax Management, Nursing Care)	
□ Foley Catheter Kit (e.g. Bard or Chinook prepackaged kits)	□ Wet Wipes (for bed-baths)
□ 4x 14g 3.125 inch needle-catheters for chest decompression	□ Absorbent pads (a.k.a. chux)
□ Chest Tube Kit*	□ Bedsheet or HPMK as drawsheet
□ 1x Chest Drainage System (e.g. Atrium or Pleur-evac; water seal preferable over Heimlich valve to prevent excessive aerosol formation)	

* Seldinger technique smaller bore chest tube kits (e.g. Thal Quick or Cook 14fr catheters) can be used for atraumatic pneumothorax; however, these are more procedurally complicated and not usually available in austere locations.

MECHANICAL VENTILATION DURING CRITICAL CARE AIR TRANSPORT (CCAT) CLINICAL PRACTICE GUIDELINE

Pressure Control Ventilation 10
Tidal Volumes for Ventilation of Patients with ARDS – ARDSNET ARMA Trial 10

I. Background & Introduction

1. Mechanical ventilation can injure the lung. Appropriate ventilator strategies will minimize ventilator induced lung injury.
2. Lung protective ventilation is appropriate for most CCAT patients, even if they do not have Acute Respiratory Distress Syndrome (ARDS).
    a. The same pathophysiologic processes are likely at work, even if they have not reached a level that meets the formal ARDS definition.
    b. There is evidence that lung protective ventilation decreases ARDS development in patients at risk, which describes most CCAT patients.
3. This document closely follows the ventilation strategy from the ARDS Network ARMA trial.
    a. This is the least harmful strategy formally studied and validated in a large trial.
    b. Some experts may choose to deviate from the strategy in an individual patient.
    c. The strategy has been modified in some respects to simplify its use.

II. Determining Stability for Flight

1. Stability for flight is a multi-factorial decision based on the patient, sending facility, CCAT team, and flight characteristics.
2. Patient characteristics
    a. PEEP and FIO2
        i. PEEP / F_IO_2 greater than 14/70% (See Appendix B.) should prompt careful consideration of risks and benefits. Such patients have little room to increase F^IO_2 or mean airway pressure if their condition worsens during flight. This does not mean patients on these settings cannot be transported safely.
        ii. All patients, including those on mechanical ventilation, will experience a decrease in PO2as ambient pressure decreases.
            - Patients with marginal gas exchange will require additional support during flight.
            - Cabin altitude restriction will lessen the impact on gas exchange.
    b. Patients on aggressive support that has been stable over time are better candidates for transport than those with increasing support leading up to flight time.
    c. Concurrent hemodynamic compromise or traumatic brain injury will complicate ventilator management and should be considered in assessing stability for flight.
3. Sending facility characteristics
    a. Type of ventilators available
    b. Availability of rescue therapies (proning, inhaled nitric oxide/prostacyclin, advanced mechanical ventilation techniques, etc.)
    c. Personnel experience and expertise

   d. Current beds available and anticipated casualties
4. Expertise of CCAT team members with advanced mechanical ventilation strategies
5. Flight characteristics
   a. Flight duration
   b. Aircraft type
   c. Patient load and complexity
   d. Altitude restriction

III. Pre-flight Preparation

Ventilator

1. Most patients can be safely transported using the Impact 731 ventilator.
   a. Allows for volume control or pressure control ventilation.
   b. Altitude compensated.
   c. Rated for patients 5kg and above.
   d. Cannot do inverse ratio.
2. The LTV 1000 ventilator offers additional capability needed in some patients but also has limitations.
   a. Inverse ratio ventilation.
   b. Better choice for pediatric transports.
   c. Unable to compensate for altitude.
   d. Unable to achieve 100% Fi02 due to turbine (93-94% highest FiO_2 attainable).

Oxygen

1. Oxygen requirements should be calculated for all patients.
   a. The LTV 1000 with high F_IO_2 and minute ventilation can exhaust a full Portable Therapeutic Liquid Oxygen System (PTLOX) during along mission. Never forego the oxygen calculation.
   b. Refer to Appendix A.
      - There is no safety factor in the calculations.
      - Additional oxygen beyond calculated requirement should be determined by each team on a case by case basis based on patient and transport characteristics.
2. Each mechanically ventilated patient should ideally have a dedicated PTLOX.
3. It is possible to have two patients on one PTLOX; Aeromedical Evacuation will make that determination if necessary.

Patient Preparation

1. Note endotracheal (ET) tube depth at the teeth that correlates to appropriate placement by CXR.
2. Secure ET tube using a dedicated securing device.
    a. If burns or facial trauma preclude this, consider securing tube to upper central incisor using silk suture or wire.
    b. Be certain that lips and tongue are not injured by device.
3. Avoid exposing airway to atmospheric pressure during ventilator changeover if PEEP is ≥ 10cm H_2O.
    a. Lung de-recruitment occurs rapidly with exposure to atmospheric pressure.
    b. Gently clamp ET tube using a Kelly clamp while the circuit is broken for ventilator changeover.
    c. Pad the Kelly clamp with tape or short pieces of rubber tubing to avoid damage to the ET tube.
    d. Do not clamp wire reinforced tubes as they will kink permanently.
4. All ventilated patients should have a heat-moisture exchanger in place.
5. Check ET tube cuff pressure prior to departure.
    a. Proper ET tube cuff inflation is mandatory to avoid aspiration, de-recruitment and ventilator malfunction (pressure too low) or damage to tracheal mucosa (pressure too high).
    b. Palpating ET tube cuff is inaccurate and should not be relied upon to estimate cuff pressure. ***Use a cuff manometer***.
    c. Goal is 20 – 30 cm H_2O (15-22 mm Hg).
    d. ET tube cuffs should be filled with air. Do not use saline.
6. All ventilated patients should have the head of bed elevated at least 30° unless there is a contraindication.
    a. Most patients will not have a contraindication. Ask the sending physician or neurosurgeon for clarification if necessary.
    b. The backrest designed for the NATO litter is the most appropriate way to elevate the head of bed.
7. All ventilated patients should have continuous $ETCO_2$ monitoring.
    a. Use caution interpreting the absolute value as it may not accurately reflect $PaCO_2$.
        - The difference between $PaCO_2$ and $ETCO_2$ reflects dead space, which can change rapidly in critically ill patients.
        - There is also likely to be some measurement error.
    b. The true value is the ability to immediately detect circuit disconnections and ventilator failures by observing changes in the waveform and to identify trends in CO_2 that may prompt arterial blood gas measurement.
    c. Providers skilled with $ETCO_2$ monitoring may infer hemodynamic data from $ETCO_2$ data.
8. All ventilated patients require gastric decompression prior to flight. Oro-gastric tube preferred to naso-gastric tube to prevention sinusitis.

9. Consider repeat CXR if > 12 hours has elapsed since most recent one or clinical condition has changed significantly.
10. Tube feeds not administered through a small bowel feeding tube should be discontinued prior to flight.

IV. Basic Ventilator Management

Mode of Ventilation

1. Avoiding injurious ventilator settings is far more important than the mode of ventilation.
2. There is no outcome based evidence favoring one mode of ventilation over another.
3. Patients in the landmark ARDSNet ARMA trial were all ventilated in volume control ventilation.
4. Pressure control has some theoretical advantages:
   - Decelerating flow waveform is more comfortable and may improve gas mixing.
   - Inverting I:E ratio is an option for increasing the mean airway pressure that is not available on the Impact 731.

Ventilator Settings

1. Tidal Volume (V_T)
   a. If using volume control:
      i. Start with V_T at 6 cc/kg
      ii. Decrease V_T as needed to achieve peak inspiratory pressure (PIP) ≤ 35 (preferably ≤30)
      iii. Do not go below V_T = 4 cc/kg.
   b. If using pressure control:
      i. Start with PIP 30-35 cm H_2O.
         - The difference between PEEP and PIP will determine V_T and is known as driving pressure or ΔP.
         - Changes in PEEP or PIP without concomitant changes in the other will change ΔP, thereby changing V_T.
      ii. Incrementally decrease ΔP (by decreasing PIP and/or increasing PEEP) as needed to achieve V_T = 6 cc/kg.
      iii. It is acceptable to target a V_T as low as 4 cc/kg if required to maintain PIP ≤ 30 - 35cm H_2O.
   c. Tidal volume should be based on predicted body weight (PBW) according to: PBW = 50+2.3 (height in inches – 60) for males. Refer to Appendix B.
   d. V_T = 8 cc/kg is acceptable in spontaneously breathing patients who are fighting the ventilator as long as the PIP or set pressure remains ≤35 (preferably ≤ 30).
   e. Do not increase tidal volume to control pCO_2.

2. Respiratory Rate
    a. Respiratory rate should be 6 – 35
    b. Adjust to achieve pH ≥ 7.3
    c. The actual pCO_2 is not important, only the pH. ******Not applicable to TBI patients******
        - Respiratory acidosis is typically very well tolerated.
        - Trying to normalize pCO_2 will worsen ventilator induced lung injury.
3. PEEP and FIO2
    a. Set initial PEEP and F_IO_2 based on MTF settings or your best estimate of what the patient needs. Minimum PEEP is 5 cm H_2O.
    b. Titrate PEEP and F_IO_2 to achieve SaO_2 92 – 96% according to the ARDSNet ARMA table in Appendix B.
    c. Recheck PIP and V_T after any change in PEEP. Adjust V_T or ΔP as needed.
        i. Increasing PEEP may increase PIP and necessitate decreasing V_T in volume control ventilation.
        ii. The LTV 1000 and 731 ventilators are not PEEP compensated.
            - Increasing PEEP without a concomitant increase in PIP will decrease ΔP and V_T.
            - Decreasing PEEP without a concomitant decrease in PIP will increase ΔP and V_T.

Alarms

1. Alarms should be set to alert the team to malfunctions or changes in physiology without causing frequent false alarms. The following guidance is a starting point but each team will determine appropriate alarm settings for each mission.
2. Suggested initial settings
    a. High pressure alarm should be set 50% above the baseline PIP (1.5 X current PIP).
    b. Low pressure alarm should be set 50% below the baseline PIP (0.5 X current PIP).
    c. High respiratory rate alarm (731 only) should be set 10 above the patient's respiratory rate.
    d. Low respiratory rate alarm (731 only) should be set 10 below the set rate.
    e. Minute ventilation alarm (LTV 1000 only) should be set 50 % below the baseline minute ventilation (0.5 X current minute ventilation)

V. Ongoing Management

Airway Suctioning

1. Suctioning every 4 hours is appropriate without copious secretions or mucous plugging.
2. Frequent suctioning may lead to lung de-recruitment and worsen gas exchange in patients with ARDS.

ET Tube Cuff Pressure

1. Significant changes may occur on ascent and descent (pressure increases with ascent, decreases with descent).
2. Pressure should be checked and documented with manometer before departure, at cruise altitude, during descent and after landing.

Mouth Care

1. Regular mouth care decreases the ventilator associated pneumonia risk.
2. Chlorhexidine is the preferred agent.
3. Recommended frequency is every 4 hours, workload permitting. Document on 3899.

Monitoring and Adjusting Ventilator Settings

1. Lung mechanics and gas exchange may change considerably during a long transport.
2. It is imperative to monitor for changes and adjust ventilator settings to meet mechanical ventilation goals.
3. Excessive V_T and inspiratory pressures are harmful and should be corrected when they are identified.
   - In volume control ventilation, incrementally change V_T by 50 cc's every 10 minutes until the desired values are achieved.
   - In pressure control ventilation, incrementally change PIP by 2 cm H_2O every 10 minutes until the desired values are achieved.
4. SaO_2 should be maintained 92 – 96% by titrating F_IO_2 and PEEP according to the ARDSNet ARMA table.
   a. F_IO_2 can be weaned up or down rapidly as any adverse effects can be quickly remedied by reversing the change.
   b. PEEP decreases
      - Rapid decreases may cause lung de-recruitment that is harmful and difficult to reverse.
      - Decrease by no more than 3 cm H_2O in a six-hour period.
   c. PEEP increases
      - Increasing PEEP can decrease cardiac output by decreasing venous return to the heart.
      - Volume loading may be needed as PEEP increases, especially when PEEP exceeds 10cm H_2O.

Management of Oxygen Desaturation

1. Confirm ET tube is in trachea using $ETCO_2$.
2. If desaturation is severe switch immediately to manual bag ventilation with high flow oxygen and PEEP valve.
3. Exclude equipment malfunction, loss of O2 supply, circuit disconnection.

4. Suction the airway (consider simultaneous bag ventilation) to verify patency and clear mucous plugs.
5. Consider increasing sedation or pharmacological paralysis if ventilator dysynchrony is present.
6. Consider pneumothorax/hemothorax.
    a. Review peak pressure trend if using volume ventilation.
    b. Review VT trend if using pressure control ventilation. V_T will decrease if significant pneumothorax develops and ΔP is not changed.
    c. Evaluate existing chest tubes for proper function.
    d. Needle decompress the chest and place a chest tube if there is suspicion of pneumothorax and concurrent hemodynamic compromise.
7. Consider recruitment maneuver and increasing PEEP to next level on titration table.
    a. Additional lung can often be recruited using sustained inflations of the lung.
    b. Classic recruitment maneuver consists of inflation to 30-40 cm H_2O for 30-40 seconds, which is difficult to do on transport ventilators.
    c. Recruitment maneuver can be performed with bag-valve manual ventilation.
        i. Set PEEP valve on bag-valve unit to 15-20 cm H_2O.
        ii. Deliver five sequential breaths, each held for 5-8 seconds.
        iii. Watch blood pressure closely and terminate maneuver immediately if hypotension develops.
        iv. Clamp endotracheal tube while switching between ventilator and bag. Exposure to atmospheric pressure will quickly result in lung derecruitment, hypoxemia and increased ventilator induced lung injury.

Monitoring Oxygen Utilization

1. When using PTLOX, periodically check amount of oxygen consumed.
2. Oxygen consumption may vary between ventilators, even with the same settings.
3. Leaks in system may cause excessive oxygen consumption.
4. Comparing actual to predicted oxygen consumption will allow early detection of excess utilization that may necessitate troubleshooting, changes in management or diverting aircraft in extreme cases.

Appendix A: Oxygen Requirements

Oxygen Consumption Tables for LTV 1000 Ventilator

Liters of Gaseous Oxygen Consumed Per Hour

FiO2 \ Minute Ventilation	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
0.3	96	103	109	116	123	130	137	144	150	157	164	171	178	185	191	198	205

0.8	1.28	1.19	1.12	1.05	0.99	0.94	0.89	0.85	0.81	0.78	0.74	0.71	0.69	0.66	0.64	0.62	0.60
0.9	1.09	1.02	0.95	0.90	0.85	0.80	0.76	0.73	0.69	0.66	0.64	0.61	0.59	0.57	0.55	0.53	0.51
1	0.95	0.89	0.83	0.78	0.74	0.70	0.67	0.63	0.61	0.58	0.56	0.53	0.51	0.49	0.48	0.46	0.44

Find the correct minute ventilation column then go down to the correct FiO2 row. The number where these intersect is the number of hours that a 1 L of liquid oxygen will operate the ventilator. 1 L liquid oxygen = 800 L gaseous oxygen. There is no safety factor in this calculation. The amount of safety factor needed should be determined by the team on a case-by-case basis.

Minutes of Use Per Full D Cylinder

FiO2 \ Minute Ventilation	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
0.3	171	159	149	140	133	126	119	114	109	104	99	96	92	88	85	82	80
0.4	81	75	71	67	63	60	57	54	51	49	47	45	43	42	40	39	38
0.5	53	49	46	44	41	39	37	35	34	32	31	30	28	27	26	26	25
0.6	39	37	34	32	31	29	28	26	25	24	23	22	21	20	20	19	18
0.7	31	29	27	26	24	23	22	21	20	19	18	18	17	16	16	15	15
0.8	26	24	23	21	20	19	18	17	17	16	15	15	14	13	13	13	12
0.9	22	21	19	18	17	16	16	15	14	14	13	12	12	12	11	11	10
1	19	18	17	16	15	14	14	13	12	12	11	11	10	10	10	9	9

Find the correct minute ventilation column then go down to the correct FiO2 row. The number where these intersect is the number of minutes that a full D cylinder will operate the ventilator. Assumes full D cylinder contains 1800 psi, is empty at 100 psi and tank factor 0.16. There is no safety factor in this calculation. The amount of safety factor needed should be determined by the team on a case-by-case basis.

Appendix B: Mechanical Ventilation in ARDS

**********Not applicable to patients with TBI**********

Volume Control Ventilation

1. Set the I:E ratio at 1:2 to 1:4. The 731 ventilator defaults to a 1:2.5 I:E Ratio.
2. Set PEEP and FiO2 according to ARDSNet ARMA Trial PEEP table to achieve SaO_2 92-96%.[1] Note that the LTV 1000 is limited to PEEP 20 and the 731 limited to PEEP 25.
3. Set tidal volume at 6 cc/Kg and note peak inspiratory pressure (PIP).[2] If necessary, decrease tidal volume by 1 cc/Kgas needed to keep peak inspiratory pressure ≤ 35 cm H_2O (preferably ≤ 30). Do not go below 4 cc/Kg. Use table below as reference for appropriate tidal volume.[3]
4. Adjust respiratory rate to achieve pH ≥ 7.34. The actual PCO_2 is not important, only the pH.

Pressure Control Ventilation

1. Set I time to achieve I:E ratio of 1:2 to 1:4.
2. Set PEEP and FiO2 according to ARDSNet ARMA Trial PEEP table to achieve SaO_2 92-96%.[1] Note that the LTV 1000 is limited to PEEP 20 and the 731 limited to PEEP 25.
3. Set inspiratory pressure to achieve a tidal volume of 6 cc/kg. If this value is > 30 cm H_2O, then decrease until it is ≤30 cm H_2O or until tidal volume is 4 cc/kg. Use table below as reference for appropriate tidal volume.[3]
4. Adjust respiratory rate to achieve pH ≥ 7.34. The actual PCO_2 is not important, only the pH.

Tidal Volumes for Ventilation of Patients with ARDS – ARDSNET ARMA Trial

Male Patients – cc's per Kg

Height				4	5	6	7	8	9	10

FiO2	0.3	0.4	0.4	0.5	0.5	0.6	0.7	0.7	0.7	0.8	0.9	0.9	0.9	1	1	1	1

<------Move across table to keep SaO_2 92 – 96 %------->

Patients falling in shaded area are not necessarily too sick for flight but risks and benefits should be considered as described in the CPG.

1. Increasing PEEP can decrease cardiac output and may cause significant hypotension in hypovolemic patients. Additional volume loading may be necessary to maintain hemodynamics.
2. This is a fairly accurate indicator of plateau pressure in our patient population. Plateau pressure is the correct parameter to follow but it cannot be easily measured with the Impact 731 ventilator.
3. Measuring the patient's "wingspan" should be used as an estimate of height. Sternum to fingertip multiplied x 2.
4. A pH of 7.2 may be an appropriate target if hemodynamics are relatively normal.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Mechanical Ventilation Basics

This CPG provides an overview of prehospital and interfacility mechanical ventilation of a patient for point of injury to en route care up to Role 2 levels of care in a standardized approach.

BACKGROUND

Appropriate consideration must be taken when placing a patient on a mechanical ventilator. Ventilator management is resource intensive and demanding which might not make it appropriate for all tactical situations. It is not without risk. The benefits should outweigh the attributable cost and risk of managing the mechanically ventilated patient, especially within the austere/ battlefield setting. Pathology associated with failure to oxygenate and failure to ventilate will most often require definitive airway interventions and appropriate mechanical ventilator support. At times, it may only serve as a temporizing measure while seeking definitive critical care. Institution of mechanical ventilation must be guided by clinical suspicion of underlying pathophysiology and clear criteria. Definitive airway management and sedation are often required for effective mechanical ventilation. See JTS CPGs *Airway Management of Traumatic Injuries and Analgesia and Sedation Management during Prolonged Field Care*. The intent of this CPG is to provide the non-critical care trained/proficient medical personnel with guidance on basic ventilator management until the appropriate level of care can be reached physically or via telemedicine in the operational environment while supporting ventilation, oxygenation, and reduce labored breathing while ensuring patient comfort. Additional JTS CPGs with ventilatory support considerations are *Acute Respiratory Failure and Wartime Thoracic Injury*.

DEFINITIONS

MECHANICS/PHYSIOLOGY OF BREATHING

1. **Respiratory drive**: The normal respiratory rate is 12-20 bpm. Respiratory drive is controlled by the hydrogen ion concentration in the cerebrospinal fluid and modified by receptors throughout the body. Increased intracranial pressure, administration of opioids and other medications may cause a decreased respiratory drive causing ventilation insufficient to maintain an adequate level of oxygenation and clearance of carbon dioxide (CO_2).[1-3]

2. **Work of breathing:** Work of breathing is the mechanical work needed to maintain oxygenation and ventilation. Pain, acidosis, and hypermetabolic states will cause an increased work of breathing. This is not necessarily pathologic but may indicate that the patient has increased CO_2 production and that respiratory support may be needed. Tachypnea secondary to shock could lead to inspiratory muscle fatigue which could eventually require mechanical ventilator support. [1-3]

3. **Lung compliance**: The tendency for the lungs to recoil from an inflated state is a good conceptual representation of compliance. Lung compliance impacts all functions of the respiratory system. Changes in lung compliance may be caused by both intrinsic and extrinsic causes. Atelectasis or fluid/blood in the alveoli can cause an intrinsic decrease in lung compliance. Examples of extrinsic causes of decreased compliance include obesity, pregnancy, burns, and chest wall injury. A decrease in lung compliance from any cause can lead to hypoxemia and hypercapnia. Fentanyl may also cause chest wall rigidity, leading to poor lung compliance. [1-3]

4. **Tidal volume (TV or V_T):** Is the volume of air that is exchanged in one breath. Decreases in tidal volume can result from external pressure (i.e. Pneumothorax, hemothorax, tension pneumothorax) by effectively reducing lung volume. Dynamic hyperinflation also known as "breath stacking" is caused by the inability to completely exhale and can lead to "auto-positive end expiratory pressure (auto-PEEP)." This may be due to inadequate exhalation time, airflow obstruction, or both. This condition leads to decreasing tidal volumes and can cause hemodynamic compromise. [1-3]

5. **Oxygenation**: The successful binding of oxygen to hemoglobin at the cellular level in the alveoli,

drives SaO_2 (arterial oxygen saturation) and SpO_2 (oxygen saturation) values. Successful alveolar gas exchange enables efficient aerobic respiration at the cellular level in all perfused body tissues. [1-3]

6. **Diffusion/exchange**: The process where oxygen (O_2) is exchanged with CO_2 on red blood cells in the alveoli/pulmonary capillaries for transport to body tissues. Pathologic conditions such as pulmonary edema, pneumonia, and acute respiratory distress syndrome (ARDS) can impair diffusion of oxygen across the alveolar membrane leading to reduced oxygen saturation of hemoglobin. [1-3]

7. **Fraction of Inspired Oxygen (FIO_2):** Normal atmospheric air contains 21% oxygen or an FIO_2 of 0.21. By increasing the percentage of oxygen delivered to the patient (supplemental oxygen), you can potentially increase the arterial oxygen saturation and oxygen content of the bloodstream. [1-3]

8. **Dead Space:** Any part of the airway where gas exchange does not occur, pharynx, larynx, trachea, bronchi, and ventilator tubing are examples.

9. **Hypoxia**: A state of O_2 deficiency in the tissue significant enough to cause impairment of function. There are four types of hypoxia that exist that must be accounted for during ventilator support: [1-3]

    - **Hypoxic Hypoxia**: Occurs when there is not enough available O2 in the surrounding environment or when decreasing atmospheric pressure prevents diffusion of O2 from the lungs to the bloodstream. Most commonly occurs during unpressurized transport at high altitude (>10,000 ft). This is correctable with supplemental oxygen.
    - **Hypemic Hypoxia**: Reduction of the blood's oxygen carrying capacity due to inadequate red blood cells (RBCs) (e.g., hemorrhage, anemia) or impairment to RBCs, carbon monoxide ([CO] poisoning, etc.). Correction of the causal factor is required.
    - **Stagnant Hypoxia**: Occurs at the circulatory level. Blood's O2-carrying capacity is adequate but circulation is inadequate (e.g., high-gravitational (G) forces, heart failure, blood vessel occlusion). Correction of underlying causal factor is required.
    - **Histotoxic Hypoxia**: Results from an interference with the use of O2 by body tissues. Alcohol, narcotics, or a poison such as cyanide (blue) is inhaled (or can be ingested) and is delivered to the tissues by the blood where it poisons the tissues, preventing use of available O2. Correction of underlying causal factor is required to positively change. [1-3]

VENTILATION

1. **Minute ventilation (V_E):** Tidal volume multiplied by the respiratory rate (normal is 60cc/kg/min), usually expressed in liters. The body regulates carbon dioxide through changes in minute ventilation. Increases in carbon dioxide leads to increased respiratory rate and/or tidal volume and increased minute ventilation (amount of air exchanged during one minute of ventilation). [1-3]

2. **Peak Inspiratory Pressure (PIP):** The greatest pressure within the lungs during inspiration. Pressures above 35mmHg have been shown to cause pressure-related lung injury (barotrauma). Ideally, pressures should remain at 30 mmHg and below. Increased peak pressures are usually due to increases in resistance within the respiratory system (e.g., tension pneumothorax, inability for adequate exhalation, edema). [1-3]

3. **Arterial Blood Gas (ABG):** This is the gold standard for evaluating acid-base status, oxygenation, ventilation and adjusting ventilation settings. If a point of care blood gas analyzer is available, this will enable targeted ventilator settings. Knowing these values will greatly improve critical care guidance via telemedicine resources. Consider placement of an arterial cannula for continuous

blood pressure and ABG sampling if it is appropriate for the operational setting and training level of the care provider.

Normal ABG values:

- pH (7.35-7.45)
- PaO2 (75-100 mmHg)
- $PaCO_2$ (35-45 mmHg)
- HCO3 (22-26 meq/L)
- Base excess/deficit (-4 to +2)
- SaO2 (90-96%)[4]

ABG DEFINITIONS

1. **pH:** Measure of hydrogen ion concentration (i.e. acid-base status). Acidosis (low pH) leads to coagulopathic states in trauma patients as well as development of potentially fatal cardiac arrhythmias.
2. **PaO_2:** Measurement of dissolved oxygen in blood, also a measurement of adequacy of gas exchange at the cellular level.
3. **$PaCO_2$:** Measurement of dissolved carbon dioxide in blood, also a measurement of adequacy of gas exchange at the cellular level.
4. **HCO_3 :** Measurement of bicarbonate in the blood, serves as a buffer against acid.
5. **Base excess:** Gives indication of metabolic component of blood gas results, most likely will not change field ventilator management but can provide information for telemedicine consultation regarding adequacy of resuscitation.
6. **SaO_2** : Percentage of oxygen bound to hemoglobin in arterial blood, correlates closely with SpO_2 values.
7. **End Tidal CO_2 ($ETCO_2$):** Measurement of carbon dioxide on end tidal expiration. Normal values are 35mmHg-45mmHg. Exhaled gasses are analyzed by either vital signs monitor or portable $ETCO_2$ devices (e.g., EMMA) a quantitative capnograph or capnometer is the clinical standard of care with invasively ventilated patients.
8. **Plateau Pressure: (PPLAT):** The pressure applied to small airways and alveoli during positive-pressure mechanical ventilation. It is measured during an inspiratory pause on the mechanical ventilator. A mechanically ventilated patient with a plateau pressure greater than 35cm is at an increased risk for barotrauma.

VENTILATOR TERMS

1. **Volume-targeted modes:** Volume constant, inspiration terminates when preset V_T delivered. Peak airway pressure is variable and increases as needed to deliver prescribed V_T. This is generally represented by a constant flow waveform.
2. **Pressure-targeted modes:** Volume variable, terminates when airflow falls below threshold level. Peak airway pressure is fixed, determined by set pressure level. This is generally represented by a decelerating flow waveform.

3. **Tidal volume (V_T):** Is the volume of gas, exchanged during a breath and commonly expressed in milliliters. V_T is generally set between 4-8 ml/kg ideal body weight (IBW), to prevent lung over distension and barotrauma.
4. **Frequency (f):** Is the rate, per minute, of breathing (patient or ventilator). Known as respiratory rate (RR).
5. **Minute Ventilation (V_e):** Is the average volume of gas entering, or leaving, the lungs per minute, commonly expressed in liters per minute. The product of V_T and RR (respiratory rate). Normal V_e is 5 – 10 L/min.
6. **Inspiratory (I) and Expiratory (E) time and I:E ratio:** Is the time period over which the V_T is delivered. Setting a shorter inspiratory time (I) results in a faster inspiratory flow rate in volume cycled ventilation. Average adult inspiratory time is 0.7 to 1 second. I:E ratio is usually 1:2.
7. **Positive end-expiratory pressure (PEEP):** Is the amount of positive pressure that is maintained at end-expiration. It is expressed in centimeters of water (cmH_2O). The purpose of PEEP is to increase end-expiratory lung volume and reduce air-space closure at end-expiration. Normal physiologic PEEP is 5 cmH_2O.
8. **Pressure Support (PS):** Delivers flow at a set pressure, generally to overcome resistance of the airway and ventilator circuit. PS can also be used to support a spontaneously breathing patient, such as with Bi-PAP.
9. **Flow:** Is the velocity at which gas is delivered to the patient, expressed in liters per minute. When the flow rate is set higher, the speed of gas delivery is faster and inspiratory time is shorter.
10. **Peak Inspiratory Pressure (PIP):** Represents the total pressure that is required to deliver the V_T and depends upon various airway resistance, lung compliance, and chest wall factors. It is expressed in centimeters of water (cmH_2O).
11. **Sensitivity or trigger sensitivity:** Effort, or negative pressure, required by the patient to trigger a machine breath, commonly set so that minimal effort (-1 to -2 cmH_2O) is required to trigger a breath.[1,3]

VENTILATOR MODES

VOLUME-TARGETED MODES

1. **Volume-targeted modes**:
    a. **Volume Assist/Control (V-AC), Assist Control (AC) or Volume Control Ventilation (VCV)**: Delivers a preset number of mandatory breaths per minute. The patient can take their own breaths in addition to mandatory breaths, with each spontaneous breath receiving the full preset tidal volume. Airway pressures can vary during delivery. [1-3]
    b. **Volume Synchronized Intermittent Mandatory Ventilation (V-SIMV)** combines mandatory breaths and supported breaths. The ventilator delivers a preset number of mandatory breaths per minute. Any breaths over the set rate will be supported with a fixed amount of pressure support. [1-3]

2. **Pressure-targeted modes:**

    a. **Pressure Support Ventilation (PSV)** supports every patient breath with a preset amount of pressure support. No mandatory breaths are given, so the patient must be spontaneously breathing.

    b. **Pressure Assist control (P-AC), or Pressure Control Ventilation (PCV)** delivers a set number of mandatory pressure controlled breaths, in which the patient receives a fixed pressure during a preset inspiratory time. Any breaths over the set rate will be pressure controlled with the same amount of pressure. The delivered tidal volume will be based on the amount of pressure applied, the lung compliance and airway resistance of the patient.

3. **Adaptive Support Ventilation (ASV):** (*Is only available on the Hamilton T1)* ASV provides intelligent ventilation mode that continuously adjusts respiratory rate, tidal volume, and inspiratory time depending on the patient's lung mechanics and effort. This is similar to "Auto-Flow" or other like settings on different brands of ventilators.

4. **Continuous Positive Airway Pressure (CPAP).**

5. **Pressure Regulated Volume Control (PRVC)** (may be Impact 731 only).

VENTILATOR ADJUSTABLE SETTINGS

1. **Tidal volume (V_T):** the volume of gas, exchanged during a breath and commonly expressed in milliliters. V_T is generally set between 4-8ml/kg IBW, to prevent lung over distension and barotrauma.[4-8]

2. **Ideal IBW:** the weight at which tidal volume is calculated against instead of using actual weight. This enables patients to be ventilated in a lung-protective strategy. A quick reference chart can be found in Appendix A. IBW can be calculated manually as follows:

    a. Male: {(Height in inches-60) x 2.2} +50 (e.g. 72in-60= 12; 12 x 2.2 = 26.4; 26.4 + 50 = IBW of 76.4 kg)

    b. Female: {(Height in inches-60) x 2.2} +45 (e.g. 65in-60= 5; 5 x 2.2 = 11; 11 + 45 = IBW of 56 kg)

1. **Minute Ventilation (V_E):** The average volume of gas entering, or leaving, the lungs per minute, commonly expressed in liters per minute. Also called minute volume. Minute ventilation is the product of V_T and RR (respiratory rate). Normal V_E is 5 – 10 L/min. [5-9]

2. **I:E Ratio:** See I:E definition. I:E might need to be adjusted for physiology that requires extended exhalation time. [5-9] For example: Asthma patient may require an I:E of 1:3, 1:4, or 1:5 to allow for more exhalation time.

3. **Flow Rate:** Is the velocity at which gas is delivered to the patient, expressed in liters per minute. When the flow rate is set higher, the speed of gas delivery is faster and inspiratory time is shorter. [5-9]

4. **Peak Inspiratory Pressure (PIP):** Represents the total pressure that is required to deliver the V_T and depends upon various airway resistance, lung compliance, and chest wall factors. It is expressed in centimeters of water (cm H_2O).

5. **Sensitivity or trigger sensitivity:** Is the effort, or negative pressure, required by the patient to trigger a machine breath, commonly set so that minimal effort (-1 to -2 cm H_2O) triggers a breath.[1,3] This is usually seen with assist modes of ventilator operation.

6. **Pressure alarms:** Pressure alarms ensure that providers are alerted to pressures that fall outside of

appropriate ranges and have potential to harm the patient via barotrauma (over-pressure) or under-ventilation (circuit disconnect or under-pressure). Pressures will be determined by placing the patient on the vent for ~1-2 minutes and determining intrinsic peak inspiratory pressure. (Labeled as PEAK on 754 Ventilator (top right); Labeled as peak on Hamilton T1 ventilator (top left); Labeled as PIP on ZOLL EMV+ (731) (right center). Standard alarm settings should be:

a. High pressure alarm: 10 cmH2O above peak airway pressure.

b. Low pressure alarm: 5 cmH2O below peak airway pressure.

ASSESSMENT

Determining the need for mechanical ventilation early is critical for the effective application of a mechanical ventilation device. Clinical suspicion is vital to adequately predict a patient who will progress to respiratory compromise. Respiratory compromise requiring ventilator support can be identified early in M-massive hemorrhage, A-airway, R-respiratory, C-circulation, and H-hypothermia (MARCH) assessment. Inability to adequately oxygenate, ventilate, or guard the airway are indications for mechanical ventilatory support. Though it is uncommon for a mechanical ventilator to be applied at point of injury, the treating provider can begin to take steps necessary to prepare for the application of a ventilator (i.e. supplemental O_2, positioning, airway interventions).

***NOTE**: Apneic patients with adequate circulation and an open airway require immediate mechanical ventilation (i.e.* bag valve mask [*BVM]).*

Though ABGs are the standard for managing patients with respiratory compromise, they are not often readily available in the operational environment. Utilization of pulse oximetry (SpO_2) and capnography/capnometry ($ETCO_2$) can provide a rapid assessment of a patient's respiratory status (devices to achieve both are readily available in medical logistics systems).

SpO_2 values < 90% are indicative of potential oxygenation issues; however, values can be unreliable due to poor perfusion and altitude.

$ETCO_2$ values >45mmHg are indicative of hypoventilation, especially in the absence of tachypnea. Values <35mmHg are indicative of hyperventilation and should be corrected in the least invasive manner. Mental preparation for mechanical respiratory support should be considered.

A high index of suspicion for sepsis or other metabolic acidosis should be maintained in patients with low $ETCO_2$ and hyperventilation.

The inability for a casualty to maintain appropriate SpO2 or $ETCO_2$ values through less invasive measures (airway adjuncts, supplemental O2, etc.) indicates the need for escalating support. For locations with point of care blood analyzers, inadequate blood gas values also indicate the need for respiratory support.

***WARNING**: Prior to the application of mechanical ventilation and/or initiation of invasive airway devices (e.g., Endotracheal Tube (ETT), extraglottic airways), patients must receive adequate sedation (and paralysis as appropriate/required). Detailed guidelines for the initiation and maintenance of this sedation can be found in Analgesia and Sedation Management during Prolonged Field Care.*

APPLICATION OF MECHANICAL VENTILATION

If respiratory insufficiency amenable to respiratory support is identified during the assessment, the initiation of timely mechanical ventilation can improve casualty outcomes. This can be as simple as bag BVM support or as complex as a critical care transport ventilator (e.g. Hamilton T1 or Zoll EMV+).[10,16]

***CAUTION**: BVM respiratory support should be utilized as a temporary measure until mechanical ventilators can be applied. BVMs deliver irregular V_T and respiratory rates leading to inconsistent blood gas values.*
***NOTE**: Many patients may require increased sedation (and paralysis) for effective ventilation. Patients who are not properly sedated may cause issues with high pressure alarms as they breathe over the ventilator increasing their minute volume and intrathoracic pressures.*

INITIAL VENTILATOR SETTINGS

*Prior to first use, ensure ventilator (as applicable) has been pre-set to utilize parameters of the user's choice. Some ventilators may be preset to deliver an inspiration time (I-Time) instead of an I:E ratio. Failure to appropriately set up and save these ventilator settings may delay use of the ventilator.

1. **MODE**: AC or ASV (Hamilton T1 only)
2. **BPM/RRate**: 14BPM (10-30 range)
3. **TIDAL VOLUME**: 6ml/kg IBW (4-8ml/kg IBW range)

   Quick Reference (Male): (Detailed reference in Appendix A)

   - 66" = ~380cc [min: 255 / max: 510]
   - 69" = ~420cc [min: 283 / max: 566]
   - 72" = ~465cc [min: 310 / max: 621]
   - 75" = ~505cc [min: 338 / max: 676]
4. **FiO_2** : 21 - 100% (0.21-1.0) (low flow O_2 @ 3 LPM (liters per minute) = ~ 40% FiO_2 [flowrate on Saros oxygen concentrator])
5. **I:E Ratio**: 1:2
6. **PEEP**: 5 [Range 5-20 cmH20]
7. **Pressure Support**: 5 [Range 5-20 cmH20] Consider adding if the patient has airway edema or is being ventilated through a narrower diameter ETT.

INITIAL VENTILATOR SETTINGS

***NOTE:** Initial Ventilator settings are based on the patient's ideal body weight (IBW) and clinical condition. However, "basic" or standard starting points are necessary to begin treatment.*

1. Set the ventilator to Volume Assist/Control.
2. Set driving mechanics by type of ventilation. Tidal Volume at 4-6 mL/kg IBW (Average adult male is 500 mL).

3. Set rate to maintain an appropriate minute ventilation (V_E) of 4-8 L/min (V_T x Rate = V_E).
    a. For a MV of 6L and a V_T of 500, set the rate at 12.
    b. Continuous capnometry or capnography is the standard for invasive airway management and should be used to monitor ventilations and as a tool to increase or decrease frequency. $ETCO_2$ is especially important for monitoring TBI cases.
4. Set appropriate PEEP. Minimum of 5 cmH2O. Start there and titrate up as needed. In hypoxic patients, consider starting at 10 cmH2O.
5. Set Fi02. Depending on clinical condition the patient may need high Fi02. Start at 100% and titrate down using arterial blood gas and SpO2 data. Do not rely on Sp02 alone (if possible).[8]
6. Set Inspiratory: Expiratory Ratio (I:E) to 1:2 for most patients. Adjust to clinical conditions.
7. Oxygen requirements can be roughly calculated using Minute Ventilation x FiO_2 fraction to determine LPM of pure O2 required (e.g., V_E of 6 LPM @ 50% FiO_2 (0.5) = 3 LPM bottled or generated O2 required.)

***NOTE**: Full D cylinder is ~425 liters O2 at 2200psi (i.e. ~141minutes O2 @ 3 LPM requirement above). Calculations should account for discrepancies in tank fill, leaks, dead space, etc. (consider a planning factor of 1.5X calculated requirement).*

TROUBLESHOOTING

Airway compromise or lost airway: If at any time the patient begins to de-saturate or develop respiratory problems, immediately disconnect the ventilator, and manually ventilate the patient with BVM (with PEEP valve if available) and 100% O_2 while correcting issues utilizing the following **D.O.P.E.** algorithm.[8]

- **Displacement**: Verify that ETT is in place, patient not extubated/tube did not move during transfer. If the ETT has advanced – pull back to original length and attempt to bag; if tube has pulled farther out of trachea, DO NOT ATTEMPT TO ADVANCE the ETT without laryngoscopy or placement of bougie to verify tracheal placement. When advancing the bougie, feel for tracheal rings or stop/ resistance at the carina. If in doubt, remove the endotracheal tube and attempt BVM. If air movement is adequate, continue to bag ventilate the patient. Upon stabilization, consider alternative advanced airways (supraglottic airway or cricothyroidotomy).

  **If ETT moves freely, access for ETT bulb rupture via cuff manometer.[10]
- **Obstructions**: Assess for secretions in ETT. Suction if indicated.
- **Pressure**: Ensure that a tension pneumothorax / hemothorax has not developed (if the chest tube is in place, ensure it is properly suctioning, not kinked or clamped). If tension pneumo/hemothorax is suspected, perform immediate needle thoracentesis. Assess the need for escharotomy if circumferentially burned. Consider additional paralysis and sedation if patient does not tolerate ventilation.[8,10]
- **Equipment**: Ensure that ventilator did not fail; O2 tank not empty. If ventilator is operational, trace all tubes to the patient connection (airway tube, transducer line, exhalation line) ensuring patency and connections.[8]

- The utilization of concurrent waveform capnography may assist in determining the causative issue while working the D.O.P.E mnemonic.

High pressure alarms / Peak airway pressure alarms (Peak pressure >35 cm H2O): Correct problems causing increased airway resistance and decreased lung compliance, including pneumothorax or pulmonary edema. Check the ventilator to ensure the prescribed tidal volume is being delivered. Check for linked/crushed tubing.

Air leaks causing low pressure alarms / volume loss: Assess, correct air leaks in endotracheal tube, tracheostomy cuff, ventilator system; recheck ventilator to make sure prescribed tidal volume is delivered.[10]

Ventilator dyssynchrony: Is a clinical entity in which ventilator gas delivery and patient respiratory mechanics are not matched. Agitation and respiratory distress that develop in a patient on a mechanical ventilator who has previously appeared comfortable represents an important clinical circumstance that requires a thorough assessment and an organized approach. The patient should not always be automatically re-sedated but must instead be evaluated for several potentially life-threatening developments that can present in this fashion.[15]

Lung hyperinflation (air trapping) and auto-PEEP: Dynamic hyperinflation is associated with positive end-expiratory alveolar pressure, or auto-PEEP. The physiologic effects of air trapping include decreased cardiac preload because of diminished venous return into the chest. This can lead to hypotension and, if severe, to pulseless electrical activity and cardiac arrest. Dynamic hyperinflation can also lead to local alveolar over-distention and rupture. Prevent and manage lung hyperinflation by decreasing tidal volume, changing inspiratory and expiratory phase parameters, switching to another mode, and correcting physiological abnormalities that increase airway resistance.[12, 13] In an emergency, auto-PEEP from air trapping can be relieved by simply disconnecting the circuit from the endotracheal tube for 3-5 seconds, and then reconnecting.

CHANGES IN RESPIRATORY STATUS

1. Assess patient's prior interventions.
2. Assess the following patient's respiratory status:
   - Rate
   - Rhythm
   - Depth
   - Effort
3. Assess monitors:
   - Oxygenation (SpO_2)
   - $ETCO_2$ (with advanced airway)
   - Cardiac monitoring if available
4. Determine cause of ventilation issue and/or ventilator alarm using DOPE mnemonic.

Table 1. Trouble shooting – DOPE Algorithm

Alarm	DOPE	Possible Cause	Troubleshooting
High Pressure	D	Mainstem intubation	If the tube has advanced and unilateral ventilation is confirmed, retract the tube to proper depth using bougie technique to maintain placement.
High Pressure	D	Esophageal intubation	If the tube is advanced and unilateral ventilation is not present, rule out esophageal intubation. If breath sounds are present over abdomen, or gastric distention noted, remove the ET tube and secure airway by other means and place gastric tube for evacuation of gastric contents.
High Pressure	O	Obstruction of ET tube	Place patient on FiO_2 1.0 (100%) and prepare suction equipment. Suction airway using standard technique. If inhalation injury is suspected (burn, agent), saline may be used to facilitate suctioning.
High Pressure	O/E	Obstruction of ventilator circuit	Ensure circuit connections are attached and not kinked paying particular attention to connections and sharp bends.
High Pressure	P	Pulmonary circuit	Rule out/treat hemo/pneumothorax.
High Pressure	P	Pulmonary circuit	Consider Pulmonary Edema. Prolong Inspiratory time if appropriate (i.e. adjust from 1:3 to 1:2 to 1:1).
High Pressure	P	Pulmonary circuit	Consider airway swelling; may need to add or increase Pressure Support
High Pressure	P	Pulmonary circuit	Evaluate Tidal Volume. Consider lowering by 1cc/kg (min. 4cc/kg).
High Pressure	P	Patient arousal	Address analgesia/sedation needs.
High Pressure	P	Stacked breath/air trapping	Disconnect patient from the circuit and allow full exhale. Address cause (patient triggering, high rate, incomplete exhalation).
High Pressure	P	Chest tube malfunction	If hemo/pneumothorax are suspected, disconnect all attachments and troubleshoot chest tube and components.
High Pressure	P	Patient position	If laying supine, elevate head of bed (HOB) to reduce gravitational pressure on the chest.
High Pressure	E	Alarm setting	After ensuring patient optimization, adjust alarm settings.
Low Pressure	D	Extubation	If tube has been removed from the trachea, secure the airway using method within scope/skill of the provider.
Low Pressure	D	Esophageal intubation	If tube is advanced and unilateral ventilation is not present, rule out esophageal intubation. If breath sounds present over abdomen, or gastric distention noted, remove ET tube and secure airway by other means and place gastric tube for evacuation of gastric contents.
Low Pressure	E	ET tube balloon	Ensure ET Tube cuff is inflated (25-35 cmH2O). If the cuff will not maintain inflation, exchange ET tube using bougie technique.
Low Pressure	E	Ventilator disconnect/leak	Ensure all connections are attached securely to the appropriate point. Run bare hand along circuit to feel any air escaping during inhalation paying special attention to valves and connections.
Low SpO2	DOPE	Assess patient	For acute desaturation, place FiO_2 at 1.0 (100%). Check chest rise and fall, $ETCO_2$, SpO2 probe placement. Check all

Alarm	DOPE	Possible Cause	Troubleshooting
			conditions from high/low pressure chart to rule out other alarm failures.
Low SpO2	x	Increase in altitude	Increase FiO_2 to compensate for decrease in pressure.
Low SpO2	x	Patient deterioration	If desaturation is gradual and presumed to be caused by patient pathology, increase PEEP and FiO_2 in a stepwise fashion according to ARDSNet table.
Low SpO2	x	Patient deterioration	Attempt alveolar recruitment maneuvers. Inflation to 30 - 40 cm H_2O for 30 - 40 seconds (difficult with PMI). Recruitment maneuver can be performed with bag-valve manual ventilation. 1. Set PEEP valve on bag-valve unit to 15 - 20 cm H_2O. 2. Deliver five sequential breaths, each held for 5 - 8 seconds. 3. Watch blood pressure closely. Terminate if hypotension develops. 4. Clamp endotracheal tube while switching between ventilator and bag. 5. Immediately assess for tension pneumothorax, if applicable.
Low SpO2	E	O2 supply	Check O2 PSI and condition of hose/connections.)
High $ETCO_2$	E	Incorrect vent settings	V_E may be too low (Adjust V_T f/I:E for patients IWB).
High $ETCO_2$	x	Hypermetabolic state	Address pain, shivering, hyperthermia / infection.
High $ETCO_2$	x	Respiratory insufficiency	Increase rate (current $EtCO_2$ x current rate/40).V_E may be too high (Ensure proper V_T/f/I:E for patients IWB).
Low $ETCO_2$	E	Incorrect vent settings	V_E may be too high (Ensure proper V_T/f/I:E for patients IWB).
Low $ETCO_2$		Ventilator dyssynchrony	If on AC and patient is not properly sedated, the patient may be breathing over the ventilator settings, increasing their V_E. Consider sedation medications followed by paralytics, as needed.
Low $ETCO_2$	x	Low perfusion state (hypovolemia or sepsis)	CHECK PATIENT'S PULSE FOLLOWING RAPID DROP. Continue to resuscitate patient within scope and skill.
Low $ETCO_2$	x	Decrease in alveolar ventilation	Suction patient if suspected mucus/secretion plug. If associated with high pressure alarm, consider alveolar distention (air trapping/stacked breathing): remove patient from ventilator and allow full exhale.
Low $ETCO_2$	x	Respiratory compensation (metabolic acidosis)	DO NOT ATTEMPT TO NORMALIZE patient's breathing without ABG and expert consultation.

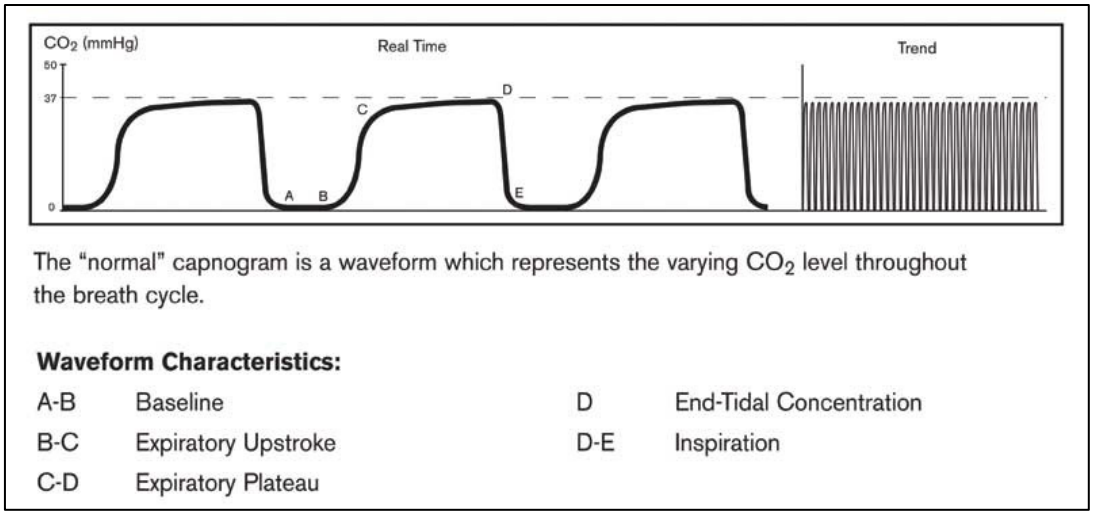
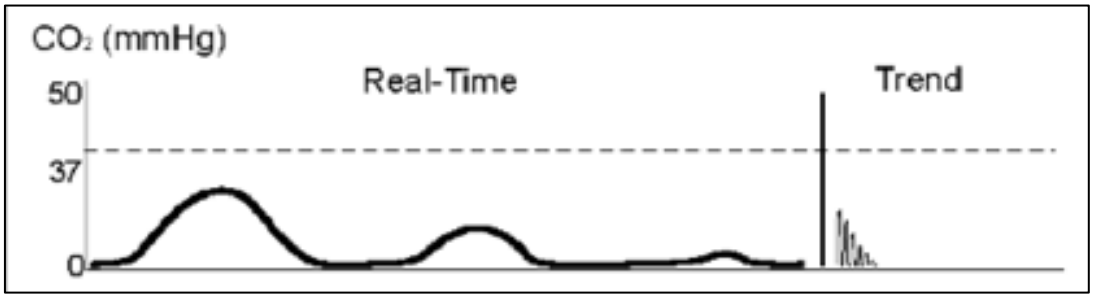
Figure 1. Recently published USAF EMS protocols

Normal Capnogram, Normal $ETCO_2$: 35-45 mmHg



Courtesy Respironics Inc. (2005). Capnography Reference Handbook.

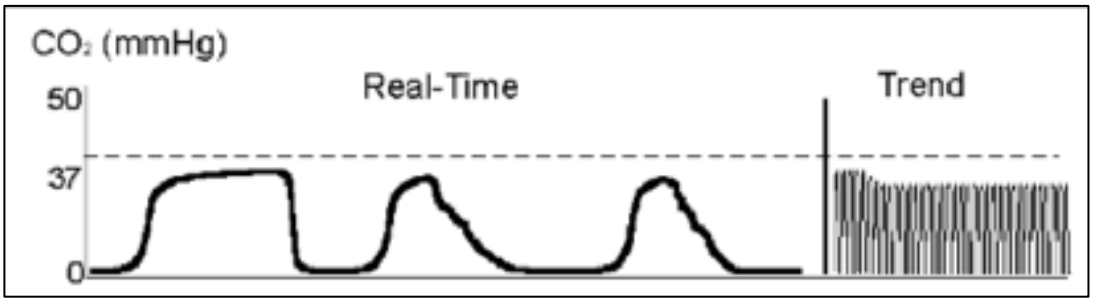
Endotracheal Tube in Esophagus



Possible causes:

- Missed intubation
- A normal capnogram is the best evidence that the ET tube is correctly positioned.
- With ET tube in the esophagus, little or no CO_2 is present.

Inadequate Seal around ET Tube

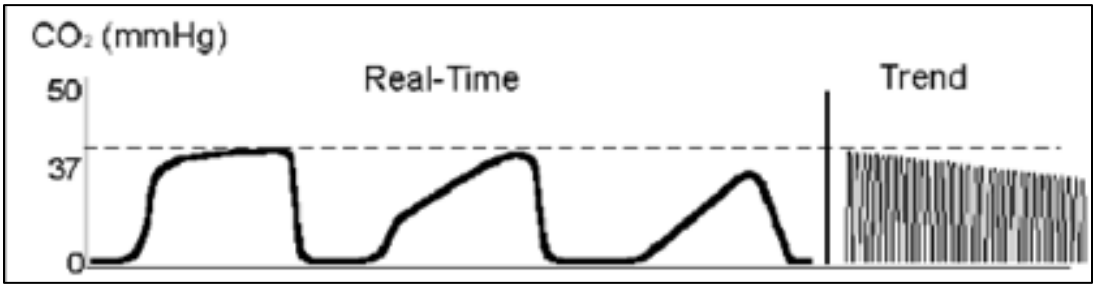


Possible causes:

- Leaky or deflated endotracheal or tracheostomy cuff

- Artificial airway is too small for the patient.

Obstruction in Airway or Breathing Circuit



Possible causes:

- Partially kinked or occluded artificial airway
- Presence of foreign body in the airway
- Obstruction in expiratory limb of breathing circuit
- Bronchospasm

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with an advanced airway requiring mechanical ventilation during transport.

INTENT (EXPECTED OUTCOMES)

1. Initial tidal volume is based on ideal body weight, targeting 6cc/kg.
2. $EtCO_2$ is monitored when available, targeting a range between 35-45 mmHg.
3. Adjustments to respiratory rate, tidal volume, F_IO_2, and PEEP are based on clinical indicators (i.e. oxygen saturation, peak airway pressure, $EtCO_2$) and documented on DA 4700 (TACEVAC Patient Care Record).
4. All patients in the population of interest arrive with $PaCO_2$ 35-45mmHg.

PERFORMANCE/ADHERENCE MEASURES

Number and percentage of patients with an advanced airway that arrive with initial $PaCO_2$ 35-45mmHg.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

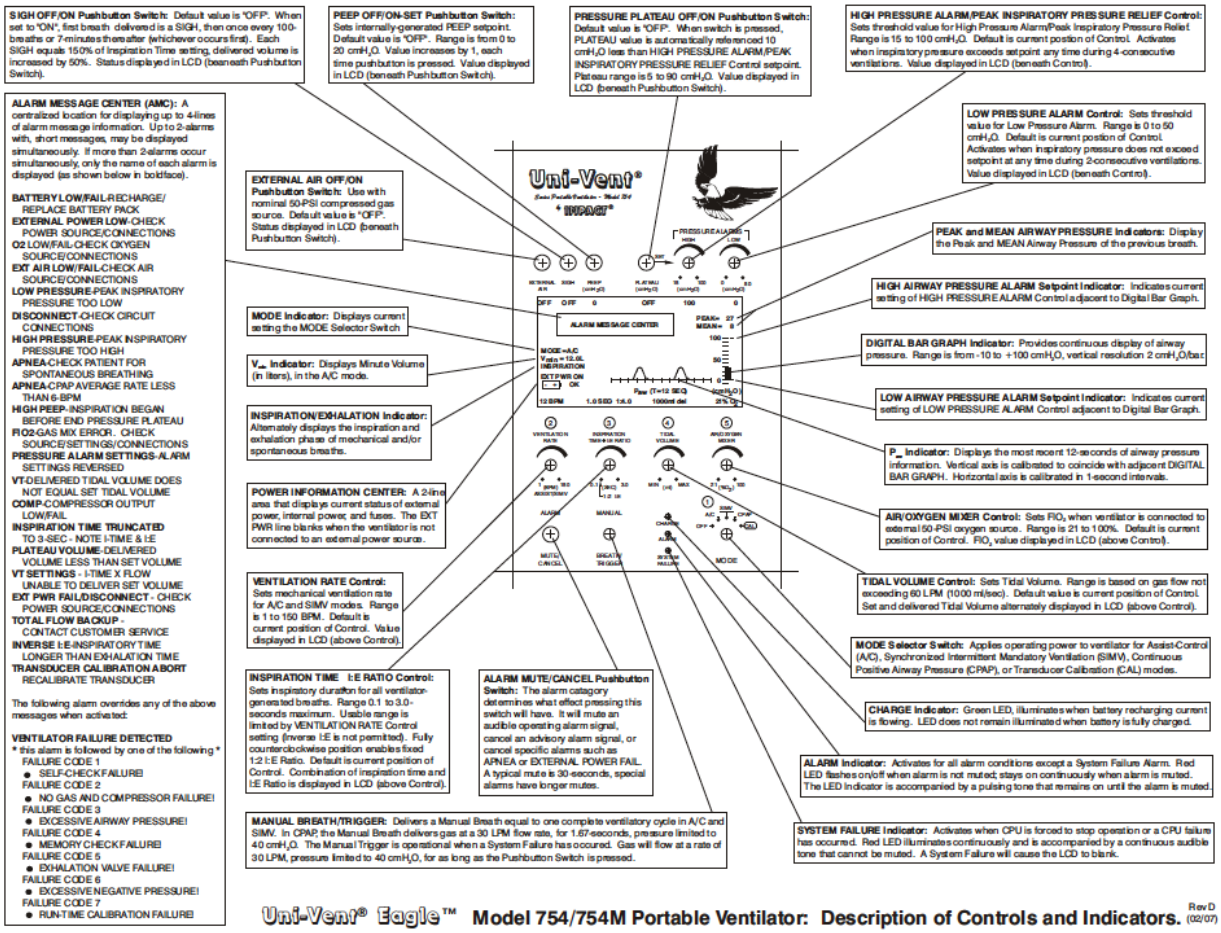
APPENDIX B: IMPACT 754

NOTE: Some Geographic Combatant Commands (GCC) have placed restrictions on use of Impact 754 Ventilators in U.S. Central Command. Check with the GCC Surgeon cell prior to utilization in theater.



SIGH OFF/ON Pushbutton Switch: Default value is "OFF". When set to "ON", first breath delivered is a SIGH, then once every 100-breaths or 7-minutes thereafter (whichever occurs first). Each SIGH equals 150% of Inspiration Time setting, delivered volume is increased by 50%. Status displayed in LCD (beneath Pushbutton Switch).
PEEP OFF/ON-SET Pushbutton Switch: Sets internally-generated PEEP setpoint. Default value is "OFF". Range is from 0 to 20 cmH2O. Value increases by 1, each time pushbutton is pressed. Value displayed in LCD (beneath Pushbutton Switch).
PRESSURE PLATEAU OFF/ON Pushbutton Switch: Default value is "OFF". When switch is pressed, PLATEAU value is automatically referenced 10 cmH2O less than HIGH PRESSURE ALARM/PEAK INSPIRATORY PRESSURE RELIEF Control setpoint. Plateau range is 5 to 90 cmH2O. Value displayed in LCD (beneath Pushbutton Switch).
HIGH PRESSURE ALARM/PEAK INSPIRATORY PRESSURE RELIEF Control: Sets threshold value for High Pressure Alarm/Peak Inspiratory Pressure Relief. Range is 15 to 100 cmH2O. Default is current position of Control. Activates when inspiratory pressure exceeds setpoint any time during 4-consecutive ventilations. Value displayed in LCD (beneath Control).
ALARM MESSAGE CENTER (AMC): A centralized location for displaying up to 4-lines of alarm message information. Up to 2-alarms with, short messages, may be displayed simultaneously. If more than 2-alarms occur simultaneously, only the name of each alarm is displayed (as shown below in boldface).
BATTERY LOW/FAIL-RECHARGE/ REPLACE BATTERY PACK
EXTERNAL POWER LOW-CHECK POWER SOURCE/CONNECTIONS
O2 LOW/FAIL-CHECK OXYGEN SOURCE/CONNECTIONS
EXT AIR LOW/FAIL-CHECK AIR SOURCE/CONNECTIONS
LOW PRESSURE-PEAK INSPIRATORY PRESSURE TOO LOW
DISCONNECT-CHECK CIRCUIT CONNECTIONS
HIGH PRESSURE-PEAK INSPIRATORY PRESSURE TOO HIGH
APNEA-CHECK PATIENT FOR SPONTANEOUS BREATHING
APNEA-CPAP AVERAGE RATE LESS THAN 6-BPM
HIGH PEEP-INSPIRATION BEGAN BEFORE END PRESSURE PLATEAU
FIO2-GAS MIX ERROR. CHECK SOURCE/SETTINGS/CONNECTIONS
PRESSURE ALARM SETTINGS-ALARM SETTINGS REVERSED
VT-DELIVERED TIDAL VOLUME DOES NOT EQUAL SET TIDAL VOLUME
COMP-COMPRESSOR OUTPUT LOW/FAIL
INSPIRATION TIME TRUNCATED TO 3-SEC - NOTE I-TIME & I:E
PLATEAU VOLUME-DELIVERED VOLUME LESS THAN SET VOLUME
VT SETTINGS - I-TIME X FLOW UNABLE TO DELIVER SET VOLUME
EXT PWR FAIL/DISCONNECT - CHECK POWER SOURCE/CONNECTIONS
TOTAL FLOW BACKUP - CONTACT CUSTOMER SERVICE
INVERSE I:E-INSPIRATORY TIME LONGER THAN EXHALATION TIME
TRANSDUCER CALIBRATION ABORT RECALIBRATE TRANSDUCER
The following alarm overrides any of the above messages when activated:
VENTILATOR FAILURE DETECTED
* this alarm is followed by one of the following *
FAILURE CODE 1
• SELF-CHECK FAILURE!
FAILURE CODE 2
• NO GAS AND COMPRESSOR FAILURE!
FAILURE CODE 3
• EXCESSIVE AIRWAY PRESSURE!
FAILURE CODE 4
• MEMORY CHECK FAILURE!
FAILURE CODE 5
• EXHALATION VALVE FAILURE!
FAILURE CODE 6
• EXCESSIVE NEGATIVE PRESSURE!
FAILURE CODE 7
• RUN-TIME CALIBRATION FAILURE!
EXTERNAL AIR OFF/ON Pushbutton Switch: Use with nominal 50-PSI compressed gas source. Default value is "OFF". Status displayed in LCD (beneath Pushbutton Switch).
MODE Indicator: Displays current setting the MODE Selector Switch
V.E Indicator: Displays Minute Volume (in liters), in the A/C mode.
INSPIRATION/EXHALATION Indicator: Alternately displays the inspiration and exhalation phase of mechanical and/or spontaneous breaths.
POWER INFORMATION CENTER: A 2-line area that displays current status of external power, internal power, and fuses. The EXT PWR line blanks when the ventilator is not connected to an external power source.
VENTILATION RATE Control: Sets mechanical ventilation rate for A/C and SIMV modes. Range is 1 to 150 BPM. Default is current position of Control. Value displayed in LCD (above Control).
INSPIRATION TIME I:E RATIO Control: Sets inspiratory duration for all ventilator-generated breaths. Range 0.1 to 3.0-seconds maximum. Usable range is limited by VENTILATION RATE Control setting (inverse I:E is not permitted). Fully counterclockwise position enables fixed 1:2 I:E Ratio. Default is current position of Control. Combination of inspiration time and I:E Ratio is displayed in LCD (above Control).
ALARM MUTE/CANCEL Pushbutton Switch: The alarm category determines what effect pressing this switch will have. It will mute an audible operating alarm signal, cancel an advisory alarm signal, or cancel specific alarms such as APNEA or EXTERNAL POWER FAIL. A typical mute is 30-seconds, special alarms have longer mutes.
MANUAL BREATH/TRIGGER: Delivers a Manual Breath equal to one complete ventilatory cycle in A/C and SIMV. In CPAP, the Manual Breath delivers gas at a 30 LPM flow rate, for 1.67-seconds, pressure limited to 40 cmH2O. The Manual Trigger is operational when a System Failure has occured. Gas will flow at a rate of 30 LPM, pressure limited to 40 cmH2O, for as long as the Pushbutton Switch is pressed.
LOW PRESSURE ALARM Control: Sets threshold value for Low Pressure Alarm. Range is 0 to 50 cmH2O. Default is current position of Control. Activates when inspiratory pressure does not exceed setpoint at any time during 2-consecutive ventilations. Value displayed in LCD (beneath Control).
PEAK and MEAN AIRWAY PRESSURE Indicators: Display the Peak and MEAN Airway Pressure of the previous breath.
HIGH AIRWAY PRESSURE ALARM Setpoint Indicator: Indicates current setting of HIGH PRESSURE ALARM Control adjacent to Digital Bar Graph.
DIGITAL BAR GRAPH Indicator: Provides continuous display of airway pressure. Range is from -10 to +100 cmH2O, vertical resolution 2 cmH2O/bar.
LOW AIRWAY PRESSURE ALARM Setpoint Indicator: Indicates current setting of LOW PRESSURE ALARM Control adjacent to Digital Bar Graph.
P.aw Indicator: Displays the most recent 12-seconds of airway pressure information. Vertical axis is calibrated to coincide with adjacent DIGITAL BAR GRAPH. Horizontal axis is calibrated in 1-second intervals.
AIR/OXYGEN MIXER Control: Sets FIO2 when ventilator is connected to external 50-PSI oxygen source. Range is 21 to 100%. Default is current position of Control. FIO2 value displayed in LCD (above Control).
TIDAL VOLUME Control: Sets Tidal Volume. Range is based on gas flow not exceeding 60 LPM (1000 ml/sec). Default value is current position of Control. Set and delivered Tidal Volume alternately displayed in LCD (above Control).
MODE Selector Switch: Applies operating power to ventilator for Assist-Control (A/C), Synchronized Intermittent Mandatory Ventilation (SIMV), Continuous Positive Airway Pressure (CPAP), or Transducer Calibration (CAL) modes.
CHARGE Indicator: Green LED, illuminates when battery recharging current is flowing. LED does not remain illuminated when battery is fully charged.
ALARM Indicator: Activates for all alarm conditions except a System Failure Alarm. Red LED flashes on/off when alarm is not muted; stays on continuously when alarm is muted. The LED Indicator is accompanied by a pulsing tone that remains on until the alarm is muted.
SYSTEM FAILURE Indicator: Activates when CPU is forced to stop operation or a CPU failure has occurred. Red LED illuminates continuously and is accompanied by a continuous audible tone that cannot be muted. A System Failure will cause the LCD to blank.

Uni-Vent® Eagle™ Model 754/754M Portable Ventilator: Description of Controls and Indicators. Rev D (02/07)

RULE OF 5S (KEEP IT SIMPLE VENT SETTINGS FOR ADULTS)

There are five numbered dials on the front of the Eagle/Impact Vent. Most settings can be set by remembering multiples of five. Do not hook up casualty to the breathing circuit until after the PEEP is set.

1. Dial 1 — Turn on to calibrate. You must calibrate the vent every time you turn it on. Turn the knob to the right. The LED display will show "Cal-Mode" and then "Cal-OK;" turn the knob to the left past Continuous Positive Airway Pressure (CPAP) and to Synchronized Intermittent Mandatory Ventilation (SIMV) or Assist Control.
2. Dial 2 — Ventilatory Rate — set at 10.
3. Dial 3 — I:E ratio of 1:2. Turn the knob all of the way to the left. This setting is generally satisfactory for all adults and pediatrics with trauma related requirements for mechanical ventilation. Medical problems like chronic obstructive pulmonary disease and asthma may require longer ratios, and this should be assessed after the initial settings have been set.
4. Dial 4 — Tidal Volume of 500 ml and adjust as needed. Tidal volume calculation is 4-8 ml/kg, therefore 6 ml/kg is recommended after the initial setting of 500.

5. Dial 5 — Air/oxygen mixer. For room air the knob will be all of the way to the left and for 100% 02 will be all of the way to the right.

IMPACT 754 VENTILATOR PRE-MISSION CHECKS AND TROUBLESHOOTING

Routine Care

Clean the unit and hose attachments with damp soapy cloth and wipe dry. Remove the inlet filter to check for dirt or debris. Check metal hose couplings for thread wear and debris.

Duty Inspection

1. Power Off Checks:
    a. Verify inspection is within the calibration date (6-month maintenance cycle).
    b. Check the air inlet is clear of obstructions and the filter is in place (Right side of vent).
    c. Verify the Gas ("OXYGEN IN" and "AIR IN") and Patient ("EXHALATION VALVE" and "TRANSDUCER") connections are clear and tight (Top of ventilator).
    d. Verify the "GAS OUT" clear leaf valve is installed and seated (reseat if loose, replace if missing).
    e. Inspect green high pressure oxygen hose for cracks, dry rot, threads, black O-ring (replace if damaged).

Connect the ventilator to a high-pressure oxygen source, turn on the oxygen tank and ensure no leaks are present. Turn off O2 when complete (conduct in environment conducive to hearing leaks).

2. Power On Checks
    a. Turn "MODE" (knob 1) to desired setting (AC, SIMV, CPAP). The ventilator will run a SELF-TEST upon set up (ventilator circuit should be disconnected). At this point, (CAL) is not required. If SELF-TEST results in a Calibration Failure, place (1) to CAL until CAL OK is displayed. If the calibration fails, the ventilator must be taken out of service.
    b. Check BATT OK
    c. Preset ventilator knobs to:
        - Rate (knob 2) 14
        - Inspiration Time (knob 3) 1:2
        - TIDAL VOLUME: 6ml/kg IBW (4-8ml/kg IBW range)

        *QUICK REFERENCE (Male): (Detailed quick reference in Appendix A)
            - 66" = ~380cc [min: 255 / max: 510]
            - 69" = ~420cc [min: 283 / max: 566]
            - 72" = ~465cc [min: 310 / max: 621]
            - 75" = ~505cc [min: 338 / max: 676]
        - FiO_2 (knob 5) 100%
        - Set HIGH pressure alarm to 35 cmH2O
        - Set LOW pressure to 15 cmH2O
    d. Turn OFF.
    e. Make sure the air inlet and gas out ports of the ventilator are protected and covered.

EMERGENCY PROCEDURES

These procedures should be practiced before being performed on live patients.

***NOTE**: Any known malfunction of the ventilator should be addressed prior to utilization. The following are not for routine use, but for emergencies when alternate ventilatory measures are not available and long term BVM is not practical.*

ALL CAUTIONS, WARNINGS, AND NOTIFICATIONS THAT CORRESPOND WITH THE 754 SCREEN WILL BE IN ALL CAPS

Inability to deliver high pressure O2 when needs exceed 21% FiO_2 (i.e. missing/unserviceable green high pressure hose).

Vent will alarm and show **O2 Low/Fail-Check Oxygen Source/Connections** on screen.

***NOTE**: First place the patient on BVM with supplemental oxygen. Second, check oxygen tank volume. Third, check the oxygen lines and connections.*

Alternative methods to increase delivered oxygen content:

1. Oxygen reservoir kit for low pressure supply (Part # 820-0097-15).
2. Oxygen reservoir fashioned from primary circuit and BVM.
   a. Connect short portion of main circuit tube to the BVM and to the air-inlet port.
   b. Connect BVM oxygen hose to the BVM and regulator.
   c. Set regulator to desired setting (~10LPM, but no lower than total minute volume).
3. Oxygen reservoir fashioned from second ventilator patient circuit.
   a. Cut/disconnect exhalation valve off of second ventilator circuit.
   b. Feed green transducer hose at least ¾ of the way down vent tubing (the goal is to get as close as possible to the air inlet port) and secure in place with tape (do not cover the end of the circuit).
   c. Connect the 90 degree/"L" shape fitting of the green transducer line to the oxygen regulator.
   d. Connect the opposite end of the vent tubing to the air inlet port.
   e. Set regulator on oxygen source to 10 LPM to deliver up to 99% F_IO_2.

Missing or damaged "Gas Out" leaf valve

Missing **Gas Out** leaf valve will trigger an alarm, give a **DISCONNECT-CHECK CIRCUIT CONNECTIONS**, no **PEAK** value will display, and little to no volume will be delivered to the patient.

1. Place the patient on BVM with supplemental oxygen.
2. Perform DOPE (Dislodgment, Obstruction, Pneumothorax, and Equipment) assessment.
3. Check **Gas Out** clear plastic leaf valve for installation and proper seating.
   - If the valve is folded, use a small object to gently unfold or push the valve back into place.
   - If missing, cover exterior **Gas Out** side ports with occlusive dressing (replacing **Gas Out** leaf valve is optimal, but is time consuming.)

WARNING: Occluding "Gas Out" side ports will enable the ventilator to provide full respirations, however, this will eliminate the anti-asphyxia function these ports provide. (Ventilator failure will result in increased resistance in spontaneous respiration) and strict surveillance must be kept on ventilator to ensure any further failure is caught immediately. Patients must immediately be transitioned to BVM in the event of any failure.

Compressor failure/alarms (may show CODE 2).

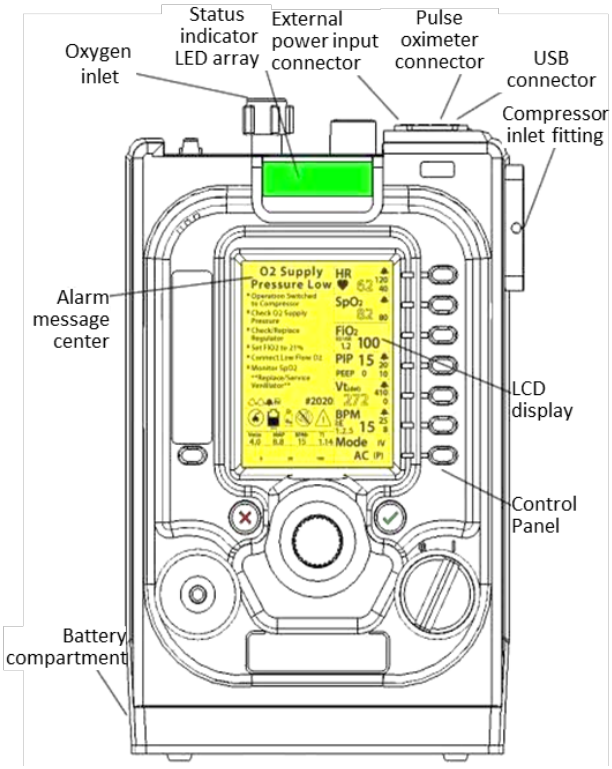
1. Place patient on BVM with supplemental O2.
2. Cycle ventilator to OFF.
3. Turn FiO_2 (knob 5) to 100%.
4. Cycle back on and to desired settings. MUST leave FiO_2 at 100%. PEEP will have to be reset when the vent is cycled on.

***NOTE**: This technique will transition the ventilator to using oxygen pressure instead of the compressor to gather drive ventilation and may hasten oxygen usage.*

Battery Failure

1. Place patient on BVM with supplemental O2.
2. Turn ventilator **OFF**.
3. Replace ventilator battery with battery from 326M suction apparatus (per the manufacturer, they are the exact same). The 326M battery is in the same location as the 754.
4. Resume normal operations. PEEP will have to be reset.

APPENDIX C: ZOLL EMV+ (731 SERIES)



1. Turn on the ventilator and ensure that the machine is functional and the battery is charged.
2. Attach the ventilator tubing and O2 tubing to the machine.
3. If the patient is a transfer on a vent, maintain ventilator settings from the medical treatment facility.
4. If the patient is "newly" on the ventilator, initial settings should include:
   a. MODE: AC
   b. BPM/RRate: 14BPM (10-30 range)
   c. TIDAL VOLUME: 6ml/kg IBW (4-8ml/kg IBW range)

   QUICK REFERENCE (Male): (Detailed quick reference in Appendix A)

   66" = ~380cc [min: 255 / max: 510]

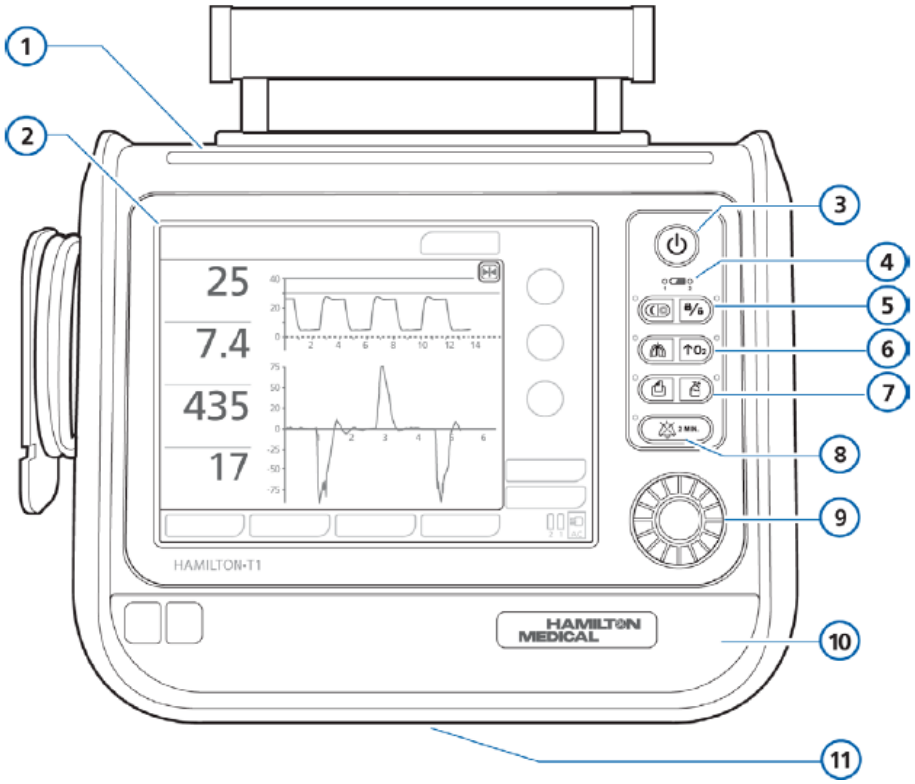
   69" = ~420cc [min: 283 / max: 566]

   72" = ~465cc [min: 310 / max: 621]

   75" = ~505cc [min: 338 / max: 676]

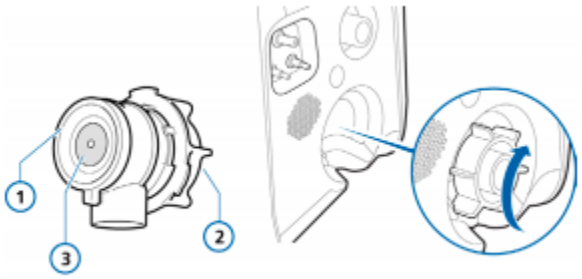
   d. FiO_2 : 21 - 100% (0.21-1.0) (low flow O2 @ 3 LPM = ~ 40% FiO_2 [flowrate on Saros oxygen concentrator])
   e. I:E Ratio: 1:2
   f. PEEP: 5 [Range 5-20]
5. Monitor waveform on the machine and visually inspect the patient to ensure no "breath stacking." If this occurs, a high-pressure alarm may sound. However, if breath stacking is suspected even in the absence of alarm – disconnect tubing and allow exhalation and decrease the I:E if possible from 1:2 to 1:4.

APPENDIX D: HAMILTON T1



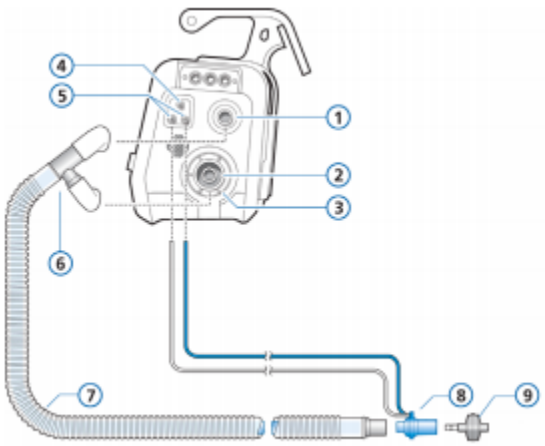
1 **Alarm lamp.** Red = high-priority alarm, yellow = medium- or low-priority alarm.
2 **Touch screen.** Provides access to measurements and controls.
3 **Power/Standby key.** Turns the ventilator on and off and accesses standby.
4 **Battery charge indicator.** Lit = battery is fully charged. Flashing = battery is charging.
5 **Day/Night key.** Switches between the Day and Night display brightness setting.
5 **Screen lock/unlock key.** Prevents inadvertent change of settings.
6 **Manual breath/inspiratory hold key.** Triggers a mandatory breath when pressed and released during exhalation. Triggers an inspiratory hold when held down during any breath phase. When active, the green indicator is lit.
6 **O2 enrichment key.** Delivers 100% oxygen for 2 min. Press the key a second time to cancel. Press **O2** key and disconnect patient to start a suctioning maneuver.
7 **Print screen key.** Save a JPG file of the current ventilator screen to a USB memory drive.
7 **Nebulizer on/off key.** Activates pneumatic nebulizer for 30 minutes or until pressed again during the inspiration phase if high-pressure oxygen (HPO) is connected.
8 **Alarm silence key.** Silences the main ventilator audible alarm for 2 min. Press the key a second time to cancel the alarm silence.
9 **Press-and-turn (P&T) knob.** Use to select and adjust ventilator settings.
10 **Front cover and battery.** The backup batteries are located inside the front cover.
11 **Underside of ventilator.** Expiratory valve bleed port. *Do not obstruct.*

1. Set up the ventilator.
    a. Install expiratory valve.



1 Expiratory valve membrane
2 Expiratory valve housing
3 Metal plate facing the ventilator

    b. Connect coaxial breathing circuit



1 To patient (inspiratory port)
2 From patient (expiratory port)
3 Adult/pediatric expiratory valve set
4 Nebulizer outlet
5 Flow sensor connectors
6 Limb connector
7 Coaxial inspiratory/expiratory limb
8 Flow sensor
9 HMEF

Connect the breathing circuit to the inspiratory and expiratory ports **(1, 2)** and the flow sensor tubes to the flow sensor connectors **(5)**.

    c. Enable Hamilton T1, EtC02, or Spo2 add ons if capable.
2. Perform pre-operational checks.
    a. Click **PreOp Checks** on main page.
    b. Conduct Tightness Test.
    c. Conduct Flow Sensor Test.

    Do not attach a patient to the ventilator without conducting both tests.
3. Select modes
    a. Input patient Gender and Height (this calculates all alarm values and “normal” ranges. ***Do not bypass this step***)
    b. Touch **Modes** to change ventilator mode.
    c. Select **ASV**.
4. Select settings
    a. Set Tidal Volume (4-8 ml/kg IBW) or Pressure Support (not to exceed 30 mmHg).

***NOTE**: This ventilator is "PEEP Compensated" which means when in Pressure Support mode if your Pressure Support is 20 and your PEEP is 10, your settings are actually 30 over 10. If you want 20 over 10, you need to see the Pressure Support at 10 and the PEEP at 10.*

This can get confusing, seek direction from medical control if necessary.

b. Set appropriate rate for age group.

c. Set Fi02 (21 to 100%).

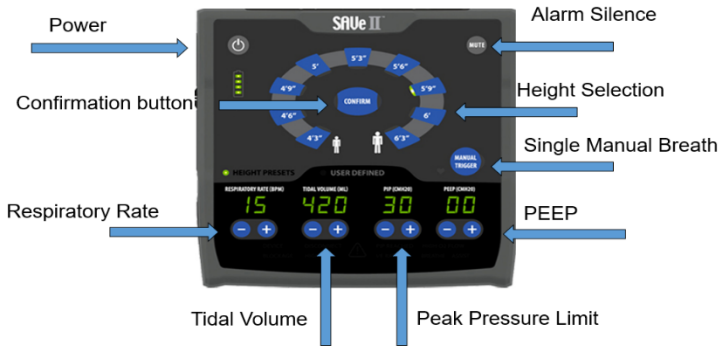
d. Set PEEP (5 to 20).

e. Adjust I:E Ratio as necessary.

5. Set Flow Trigger (0.5 to 5). Press the start ventilation button prior to connecting patient.
6. **Once the patient is on the ventilator, you may have to adjust alarm parameters**

APPENDIX E: SAVE II

NOTE: The SAVe II is designed for use in place of a Bag Valve Mask (BVM) in the pre-hospital environment. The intended use is to provide ventilator support or Positive Pressure Ventilation (PPV) to adults weighing >45kg (99lbs.).



1. Power on. The device will run through a self-test (all lights will illuminate, and will alarm for a moment).
2. Connect tubing: Tubing will only attach one way. Ensure any patient circuit is being attached on the light grey side of ports, as pictured above. Ensure all connections of the circuit are tight; loose connections may cause low pressure or disconnect alarm.
3. Select height and confirm (failure to select confirm will not change and or set appropriate settings). Any time a change is made, the CONFIRM button must be pressed. The device will default to a PEEP of 0; ensure adjustments are made IAW CPG or protocol.

4. Attach to airway device.

5. Confirm ventilations.

6. Adjust PEEP if needed by setting PEEP and hitting confirm.

***NOTE**: This device is intended for short term or transport use and is not intended to replace other ventilators available. Consider transitioning the patient to another ventilator (731, 754, or Hamilton T1) as soon as feasible.*

APPENDIX F: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of Department of Defense (DoD) policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion of off-label uses in CPGs is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion of off-label uses in CPGs is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, the DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

CLINICAL PRACTICE GUIDELINES FOR MILITARY WORKING DOGS

Military Working Dogs (MWDs) are critical assets for military police, special operations units, and others operating in today's combat environment. Expectations are that injured working dogs will receive the highest level of resuscitative care as far forward as possible, often in the absence of military veterinary personnel.

These guidelines are not a substitute for clinical judgments. (CPG ID: 16)

CHAPTER 1

Scope of Healthcare Provider Responsibilities

These clinical practice guidelines (CPGs) apply to deployed human healthcare providers (HCPs) in combat or austere areas of operations. Veterinary care is established at multiple locations throughout theater, and the veterinary health care team is the MWD's primary provider. However, HCPs are often the only medical personnel available to MWDs that are critically ill or injured. The reality is that HCPs will routinely manage working dogs in emergencies before they are ever seen by veterinary personnel.

Care by HCPs is limited to circumstances in which the dog is too unstable to transport to supporting veterinary facilities or medical evacuation is not possible due to weather or mission constraints; immediate care is necessary to preserve life, limb, or eyesight; and veterinary personnel are not available. HCPs should only perform medical or surgical procedures – within the scope of their training or experience – necessary to manage problems that immediately threaten life, limb, or eyesight, and to prepare the dog for evacuation to definitive veterinary care. Routine medical, dental, or surgical care is not to be provided by HCPs.

Emergent surgical management of injured MWDs may be necessary by HCPs to afford a chance at patient survival. This should be considered only if:

- The provider has the necessary advanced surgical training and experience.
- The provider feels there is a reasonable likelihood of success.
- The provider has the necessary support staff, facilities, and monitoring and intensive care facilities to manage the post-operative MWD without compromising human patient care.
- Emergent surgical management should be considered only in Role 2 or higher medical facilities and by trained surgical specialists with adequate staff. Direct communication with a US military veterinarian is essential before considering surgical management, and during and after surgery, to optimize outcome.

Considerations

Working dogs operated by allied military forces and DoD contractors may be presented for medical care by HCPs. Established agreements permit HCPs to provide necessary emergency care, just as if these dogs were MWDs.

The overarching goal when managing injured dogs is return to normal function and duty (RTD). Within reason, however, consider the adoption potential for dogs. Adoption of MWDs no longer fit for duty is authorized. Many MWDs with career-ending injuries have been successfully managed and ultimately adopted, some suffering these injuries while deployed. Consider emergency care, even if RTD is not likely but adoption is possible. HCPs should be reasonable, however, when considering the extent to which resources are allocated; dogs with multiple limb amputations or severe brain injury, for example, are not adoptable.

Information concerning MWDs (e.g., unit of assignment, operating location, illness or injury data, functional status) should be considered confidential and treated as such.

General Handling and Management of MWDs

MWDs are unpredictable and potentially dangerous animals, especially when ill, injured, or stressed, and especially when not under the control of a trained handler.

The dog handler is the best person to control the MWD; they have the most accurate information about past medical problems and the current situation, and they have first aid training and can assist in care. The MWD unit is responsible for providing a handler at all times.

Safety of HCPs and bystanders is paramount:

- Never examine a MWD without a handler present. Remove MWDs from areas where handlers are being treated; instances have occurred when MWDs aggressed on HCPs that the dog felt were threatening the handler.
- MWDs should be muzzled whenever being handled, unless medical issues prevent muzzling. Standard muzzles issued to handlers are ideal; however, roll gauze can be used for temporary control, looped tightly around the muzzle twice, and tied behind the head. Remove the muzzle when not actively handling the dog, if the dog is sedated or anesthetized, if the dog is having breathing difficulty, or if temperature extremes prevent cooling by panting.
- MWDs must be controlled and supervised at all times, especially if sedated or anesthetized. A handler must be immediately available 24 hours a day when MWDs are in a facility.
- MWDs must never be transported without a handler. If available, portable kennels are the best means of transport for stable MWDs. If a portable kennel is not available, MWDs transported in aircraft should be muzzled if their medical condition permits.

Evaluation and Treatment Tips

Note: Chapters 2-22 guide HCPs in management of specific scenarios involving life- or limb-threatening problems with MWDs.

Some supplies and equipment are unique to managing dogs, or differ from that used on people. Experience shows it is ideal to centrally locate these items in the area where injured dogs will be managed. Coordinate with supporting veterinary personnel for these items. Examples are dog hair clippers, dog muzzles, canine oxygen face masks, neonatal and pediatric blood pressure cuffs, and size 10mm and 11mm endotracheal and tracheostomy tubes. Durable medical equipment should be routinely disinfected for re-use, as is done after use on human patients.

MWDs with a catheter or bandage of any kind, or with wounds of any kind should be prevented from self-trauma and removal of devices. The simplest options for preventing self-trauma and device removal are either a loose-fitting muzzle (short-term use only) or application of a modified plastic bucket with the bottom cut off, secured around the neck using a collar (See Figures 21 and Figure 22).

Liberally clip hair at catheter sites, and around all wounds and over traumatized areas to reveal areas of "hidden" injury that might otherwise be missed.

Performance Improvement (PI) Monitoring

Intent (Expected Outcomes)

- HCPs manage MWDs safely in emergent situations to provide life-saving measures to resuscitate and stabilize injured dogs until evacuation is coordinated to a veterinary facility.
- HCPs do not perform medical or surgical procedures for non-emergent reasons or if veterinary personnel are available.
- HCPs promptly coordinate veterinary support and provide timely feedback in instances in which care is provided to MWDs.

Veterinary personnel will remain integrally involved in the decision chain for all MWD care issues. Current locations and contact information for theater veterinarians are found on the Veterinary Common Operating Picture or by contacting the TF MED/MED BDE TOC.

Performance/Adherence Measures

- Compliance review by supporting veterinary personnel of key data sources.
- Face-to-face discussions between supporting veterinary personnel and HCPs providing care.

Data Source

- Patient record generated by HCPs during care (Canine Resuscitation Record; See Chapter 22).
- Canine Tactical Combat Casualty Care card (See Chapter 22).

System Reporting and Frequency

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed biannually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Director, JTS Program Manager, and the JTS PI Division.

Responsibilities

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

The Director, DoD Military Working Dog Veterinary Service is responsible to update the MWD CPG in coordination with the JTTS and JTS Directors and is the final veterinary approval authority.

HCPs will:

- Notify veterinary personnel immediately upon notification of an inbound MWD or on the arrival of a MWD in any medical facility, especially in emergent situations.
- Complete medical care documentation as detailed in Chapter 22 any time emergent care is provided.

Normal Clinical Parameters for MWDs

Table 1. Normal Vital Signs at Rest.

NORMAL VITALS AT REST	
Temperature (rectal)	101° to 103° F
Heart/Pulse rate	60 - 80 bpm
Respiratory rate	16 - 30 bpm *(note that controlled panting is common in MWDs)*
Blood pressure	Systolic 120 mmHg, Diastolic 80mmHg, Mean 90-100 mmHg

Table 2. Complete Blood Cell Count Parameters.

BLOOD CELL COUNT PARAMETERS	
WBC	6 - 17 X 10^3/µL
RBC	5.5 - 8.5 X 10^6/µL
Hgb	12 - 18 g/dL
Hct	35 - 45%
MCV	60 - 77 fl
MCH	19.5 - 24.5 pg
MCHC	32 - 36 g/dL
Platelet count	200 - 900 X 10^3/µL

Table 3. Blood Chemistry Parameters.

***NOTE**: Results from serum chemistry analyzers calibrated for human serum may be unreliable or misleading based on methodology for **albumin** and **total calcium** concentrations.*

BLOOD CHEMISTRY PARAMETERS				
Albumin	2.5 - 4.4 g/dL		GGT	0 - 7 U/L
ALP	20 - 150 U/L		Glucose	60 - 110 mg/dL
ALT	10 - 118 U/L		HCO_3	17 - 25 mmol/L
Amylase	200 - 1200 U/L		Lactate	1.5 - 2.0 mmol/L
AST	14 - 45 U/L		pCO_2	24 - 38 mmHg
Bicarbonate	12 - 27 mmol/L		pH	7.35 - 7.45
BUN/SUN	7 - 25 mg/dL		pO_2	85 - 100 mmHg
Calcium (total)	8.6 - 11.8 mg/dL		Potassium	3.7 - 5.8 mmol/L
Chloride	105 - 111 mmol/L		Sodium	138 - 160 mmol/L
Creatine kinase	20 - 200 U/L		Total bilirubin	0.1 - 0.6 mg/dL
Creatinine	0.3 - 1.5 mg/dL		Total protein	5.4 - 8.2 g/dL

Unique Clinical Anatomy and Venous Access

Dogs differ anatomically and physiologically in several key areas in comparison to people. Knowledge of these differences will assist HCPs when managing MWDs.

Most MWDs are German shepherd dogs, Belgian Malinois, and Labrador retrievers, with an weight of 50-80# (23-36 kg). Dose drugs based on actual body weight whenever possible.

Canine blood can be tested using analyzers designed for people, with generally reliable results. Interpretation of results may be unreliable or misleading for albumin and total calcium, however, due to species-specific methodology differences. For all other parameters, if the results appear reasonable, trust them for decision-making.

Venous blood sampling and IV catheterization sites:

Use the cephalic or lateral saphenous veins for routine blood sampling, drug administration, and routine intravenous fluid therapy. Use the external jugular vein for long-term fluid therapy, large volume fluid delivery, and repeated blood sampling.

- Cephalic vein on the cranial (superior) aspect of the forearm (See Figures 1, 2, and 3).
- Lateral saphenous vein on the lateral aspect of the hind limb at the distal tibial area (See Figure 4).
- External jugular vein in the jugular furrow of the neck (See Figures 5-16). Standard human central venous catheter kits can be used; the Seldinger technique is most reliable.

Figure 1. Cephalic Vein Location on Superior Aspect of Forearm.

Figure 1 shows cephalic vein location on the cranial (superior) aspect of the forearm.

The vein is best punctured toward the elbow, as the accessory cephalic vein and cephalic vein join in a Y-shaped configuration more distally (toward the carpus).

Figure 2. Occluding the Vein.

Figure 2 shows proper technique for an assistant to occlude the vein, while extending the elbow joint. The assistant's thumb occludes the vein while rolling the vein outward at the elbow.

Figure 3. IV Catheter in Cephalic Vein of Forelimb.

Figure 3 shows properly placed and secured IV catheter in the cephalic vein of the forelimb of a MWD.

Figure 4. Lateral Saphenous Vein Location.

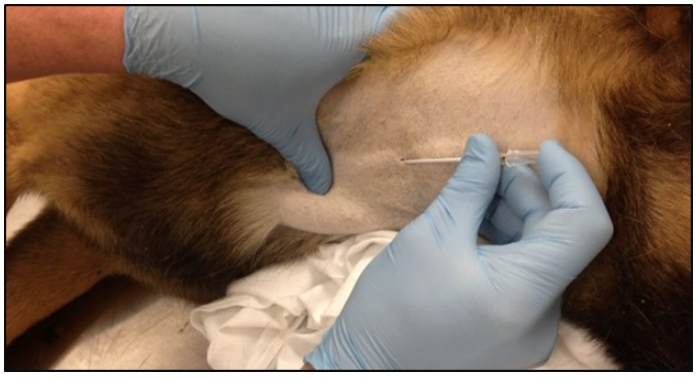
Figure 4 shows location of the lateral saphenous vein on the hind limb of a MWD, located on the lateral aspect of the distal tibial area, coursing caudodorsally from the hock (ankle) and over the gastrocnemius tendon.

Figures 5 – 16: External Jugular Vein Location and Central Venous Catheterization.

Figure 5 shows the right external jugular vein (dotted lines) located in the right jugular furrow. The vein is best punctured distal to the junction of the more-proximal tributaries (the optimal insertion site is noted by the red oval). Hair should be clipped and a sterile preparation should be performed.

Figure 6 shows a small skin nick (noted in the red oval) created over the intended catheter insertion site to facilitate penetration of the thick skin of the dog. This nick can be made with the tip of a #11 scalpel blade or the bevel of an 18-gauge needle.

Figure 7 shows insertion of a large bore catheter-over-needle through the skin nick, penetrating the skin and entering the external jugular vein. Note the use of the thumb of the opposite hand to occlude the vein. ***In this figure, and in Figures 8-12, sterile draping is removed to provide better visualization; perform catheterization using sterile technique.***



Jugular Vein Location & Central Venous Catheterization

Figure 8 shows full insertion of the over-the-needle catheter into the external jugular vein, after removal of the needle.

Figure 9 shows insertion of a Seldinger guide wire adapter into the hub of the catheter that has been placed into the external jugular vein.

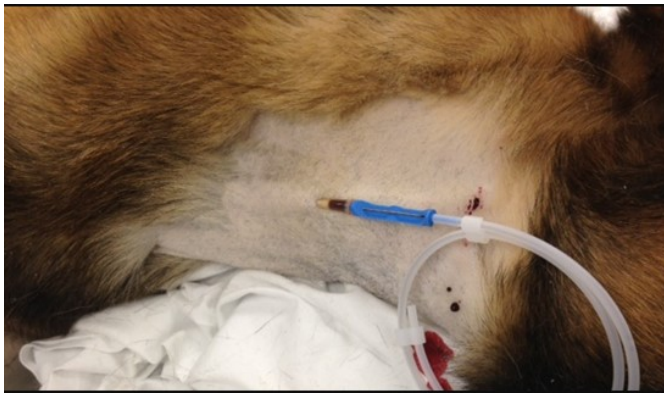


Figure 10 shows advancement of the Seldinger guide wire through the catheter and into the external jugular vein. Once the guidewire is advanced about two-thirds of its length into the vein, remove the catheter, leaving only the guidewire in place.

Figure 11 shows initial advancement of the multi-lumen central venous catheter over the guidewire. Use of a dilator (not shown) is often necessary before this step to enlarge the puncture site in the skin.

Figure 12 shows advancement of the catheter into the external jugular vein. Note extension of the guidewire from the proximal end of the catheter (red oval).

Figure 13 shows full insertion of the catheter into the external jugular vein, complete removal of the guidewire, and attachment of an injection port on the catheter hub.

Jugular Vein Location & Central Venous Catheterization

Figure 14 shows the optimal method to secure central venous catheters to the dog's skin using separate sutures at the wings of the catheter hub and circumferentially around the catheter base.

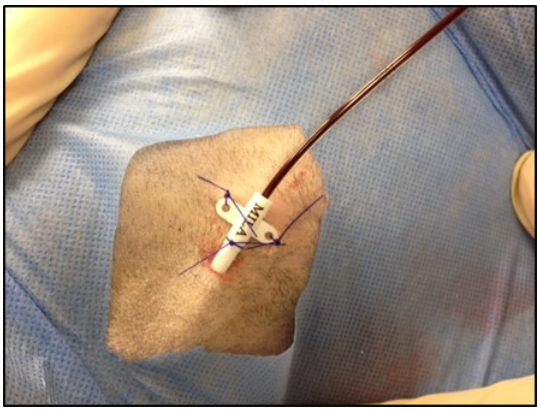

Figure 15 shows the optimal method to initially secure the central venous catheter using roll gauze or cast padding. Note that the catheter tubing (dotted line) is gently curved caudally and secured between snug layers of gauze/padding.

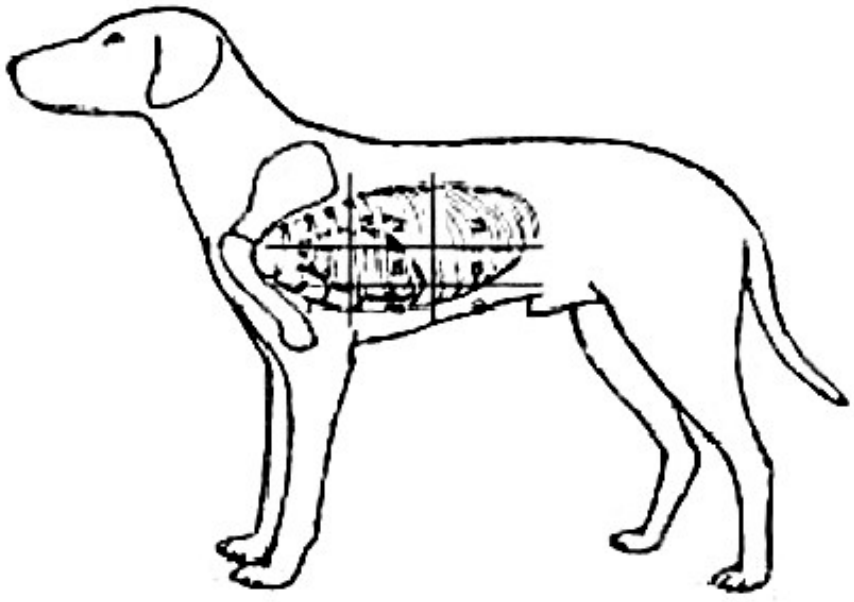
Figure 16 shows the optimal method to completely secure the central venous catheter using non-adherent bandage material placed over the underlying roll qauze/padding. Note: At least 2 fingers can be inserted beneath the bandage, ensuring the bandaging is not too tight.

Routine Cardiovascular Monitoring

- Heart sounds are best auscultated over the lower lateral thoracic wall between the 4th-5th intercostal spaces, typically where the elbow crosses the chest wall when the forelimb is pulled caudally (See Figure 17).

Figure 17. Heart Sounds Location.

Figure 17 shows optimal location for auscultation of the heart sounds and palpation of the heartbeat, in the 4th-6th intercostal space just above the sternum and just caudal to the elbow.



- The arterial pulse is best palpated at the femoral artery on the medial aspect of the proximal thigh in the inguinal area, or at the dorsal metatarsal artery on the dorsal aspect of the proximal hind paw. (Figure 18)
- Arterial blood pressure measurement is best measured non-invasively using the dorsal metatarsal artery, located on the dorsal aspect of the hind paw. Alternative sites are the lower forearm and tail base. Neonatal (size 4 or 5) or pediatric (size 6-8) human cuffs and an oscillometric technique work well. Use pediatric settings on the monitor.

Figure 18. Pulse location.

Figure 18 shows location for palpation of the femoral arterial pulse, in the inguinal region on the medial aspect of the proximal thigh.

Routine Cardiovascular Monitoring

- ECG adhesive electrodes should be taped to the pads of the paws of the left forelimb (black lead), right forelimb (white lead), and left hind limb (red lead), as shown in Figure 19. 3-lead electrocardiograms are the norm and are sufficient. Canine ECG complexes resemble human complexes, with minor variations in key electrocardiographic intervals.

Figure 19. Placement of ECG Electrode Pads.

Figure 19 shows a technique for placement of adhesive ECG electrodes.

- Pulse oximetry probes used for people (typically finger probes) are best placed on the tongue for optimal reliability (See Figure 20) in unconscious, sedated or anesthetized dogs. In conscious dogs, use the ear pinna, lip fold, or flank skin fold; while not optimal for oximetry, these alternate sites generally yield reliable results in most instances.

Figure 20. Placement of Human Pulse Oximeter Finger Probe on Tongue.

Figure 20 shows a technique for placement of standard human pulse oximeter finger probe on the tongue of an anesthetized dog.

Prevention of Self-trauma & Removal of Devices

Military working dogs will chew at catheters, bandages, and monitoring devices, and will excessively lick and chew at wounds to the point of causing foreign body ingestion and self-trauma. Use muzzles in the immediate period of initial monitoring and care to prevent this.

Tape catheters around the entire circumference of the limb, including the hub and catheter adapter port to adequately secure the catheter. The tape should be snug, but caution used to prevent excessive tightness that will result in distal edema.

For long-term management, a simple option is to fashion a preventive device. The bottom of a standard bucket is removed, 4-5 holes are drilled in the base of the bucket, and cable ties are used through these holes to secure the bucket to the dog's leather collar. The bucket-collar combination is then applied. (See Figures 21 and 22). Supporting veterinary personnel or MWD handlers should provide these.

Figure 21 shows the technique to make a bucket to prevent self-trauma by MWDs.

The bottom of a standard plastic bucket is removed, 4-5 holes are drilled near the base, and cable ties are used to secure the bucket to the dog's leather collar.

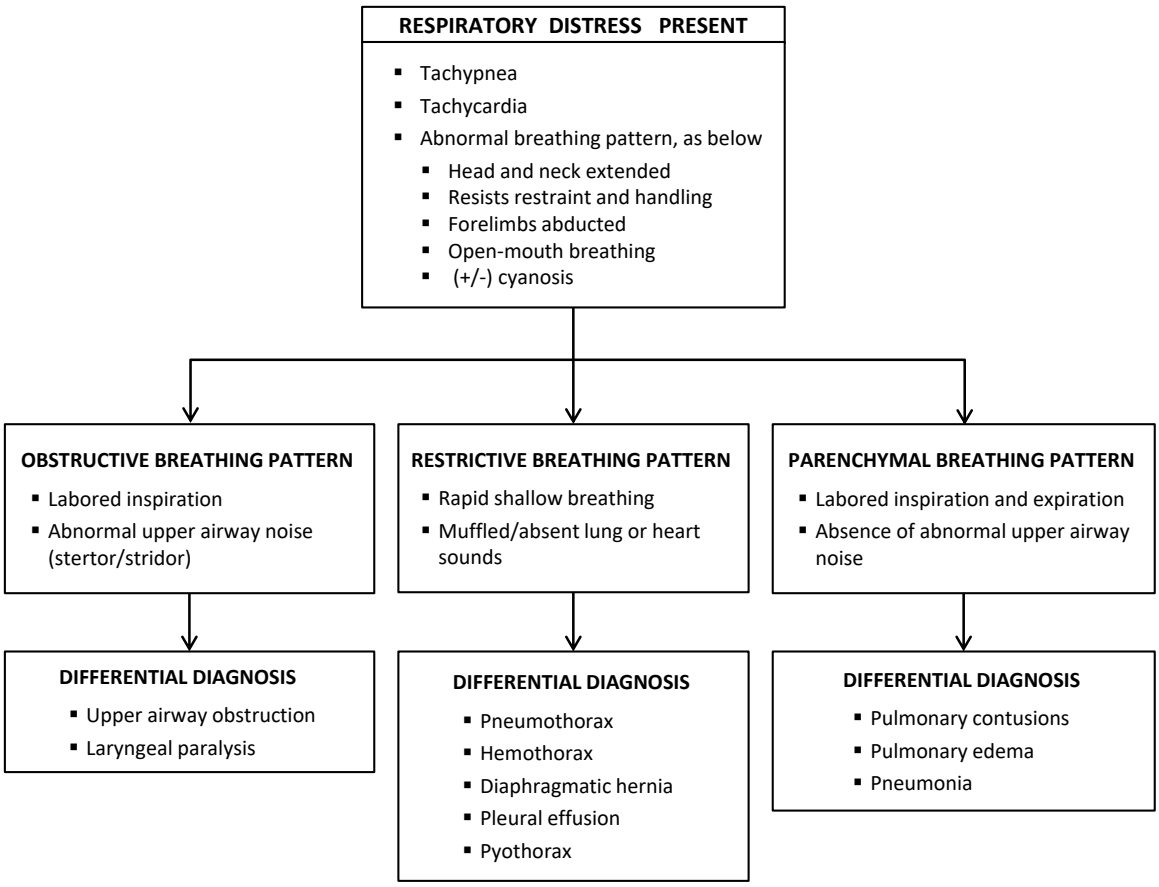
Figure 22 shows the bucket-collar device applied to a Military Working Dog.

Emergency Airway Management

Respiratory distress develops in deployed MWDs most commonly due to trauma. MWDs in respiratory distress are fighting to get oxygen: they are anxious, usually have obvious labored breathing, usually have their head and neck extended and elbows and upper legs held away from the chest, don't want to lie down, and fight restraint and handling. Cyanosis, if present, is a late finding. MWDs in respiratory distress typically have 1 of 3 characteristic breathing patterns that help localize the problem.

Figure 23 presents a clinical algorithm for differentiating the most likely cause of a patient's distress based on the pattern of breathing.

Figure 23. Clinical Algorithm for Differentiating Causes of Respiratory Arrest Based on Breathing Pattern.[1]



Oxygen Supplementation

Oxygen supplementation is essential. Provide 100% oxygen to all trauma patients and any patient that is showing signs of respiratory distress, until proven unnecessary.[4] Oxygen cages (makeshift or manufactured) and oxygen tents are impractical or not available in the typical HCP situation, so evacuate the MWD to the supporting veterinary facility if long-term oxygen therapy is necessary.

Conscious MWDs: Use face mask or "blow by" technique (hold end of oxygen tubing or circuit as close to nose and mouth as possible or attach to muzzle) using high flow rates of 10-15 L/min.[5] Use caution; ensure handler has control of the MWD at all times. Agitated, distressed or dyspneic MWDs will bite and can cause serious injury to the HCP or MWD handler. Figure 24 shows simple yet effective techniques to safely provide "blow-by" oxygen supplementation to muzzled MWDs. While not the ideal method, acceptable inspired oxygen concentrations of 40-70% are achieved with this technique,[5] which may be life-saving.

Unconscious MWDs: Use tracheal insufflation, orotracheal intubation, or tracheostomy (see Table 4, Table 5, and Table 6 for techniques).

Figure 24. Administration of Supplemental Oxygen.[4]
Figure 24 shows techniques for safe administration of supplemental oxygen to conscious or fractious muzzled dogs.

Upper Airway Obstruction with Obstructive Breathing Pattern

A patient with an obstructive breathing pattern typically has respiratory distress characterized by labored inspiration and abnormal upper airway noise such as stridor or stertor (See Figure 23).

- Common causes in trauma patients are facial and oropharyngeal swelling (jaw fractures, facial trauma), cervical injury (tracheal compression by hemorrhage in neck area, muscle edema), direct tracheal injury, severe snake and insect envenomation, bite wounds, smoke inhalation, electrocution, and foreign objects.
- Diagnosis is usually obvious based on history of trauma and presenting signs. For every trauma patient, carefully ensure the airway is open by physically opening the mouth, examining the oral cavity, and watching the patient breath. Palpate and examine the face, muzzle, nose, mouth, external laryngeal area, and trachea for deformities, traumatic wounds, or other abnormalities
- If the airway is not patent, immediately takes steps to open the airway (See Figure 25 next page).

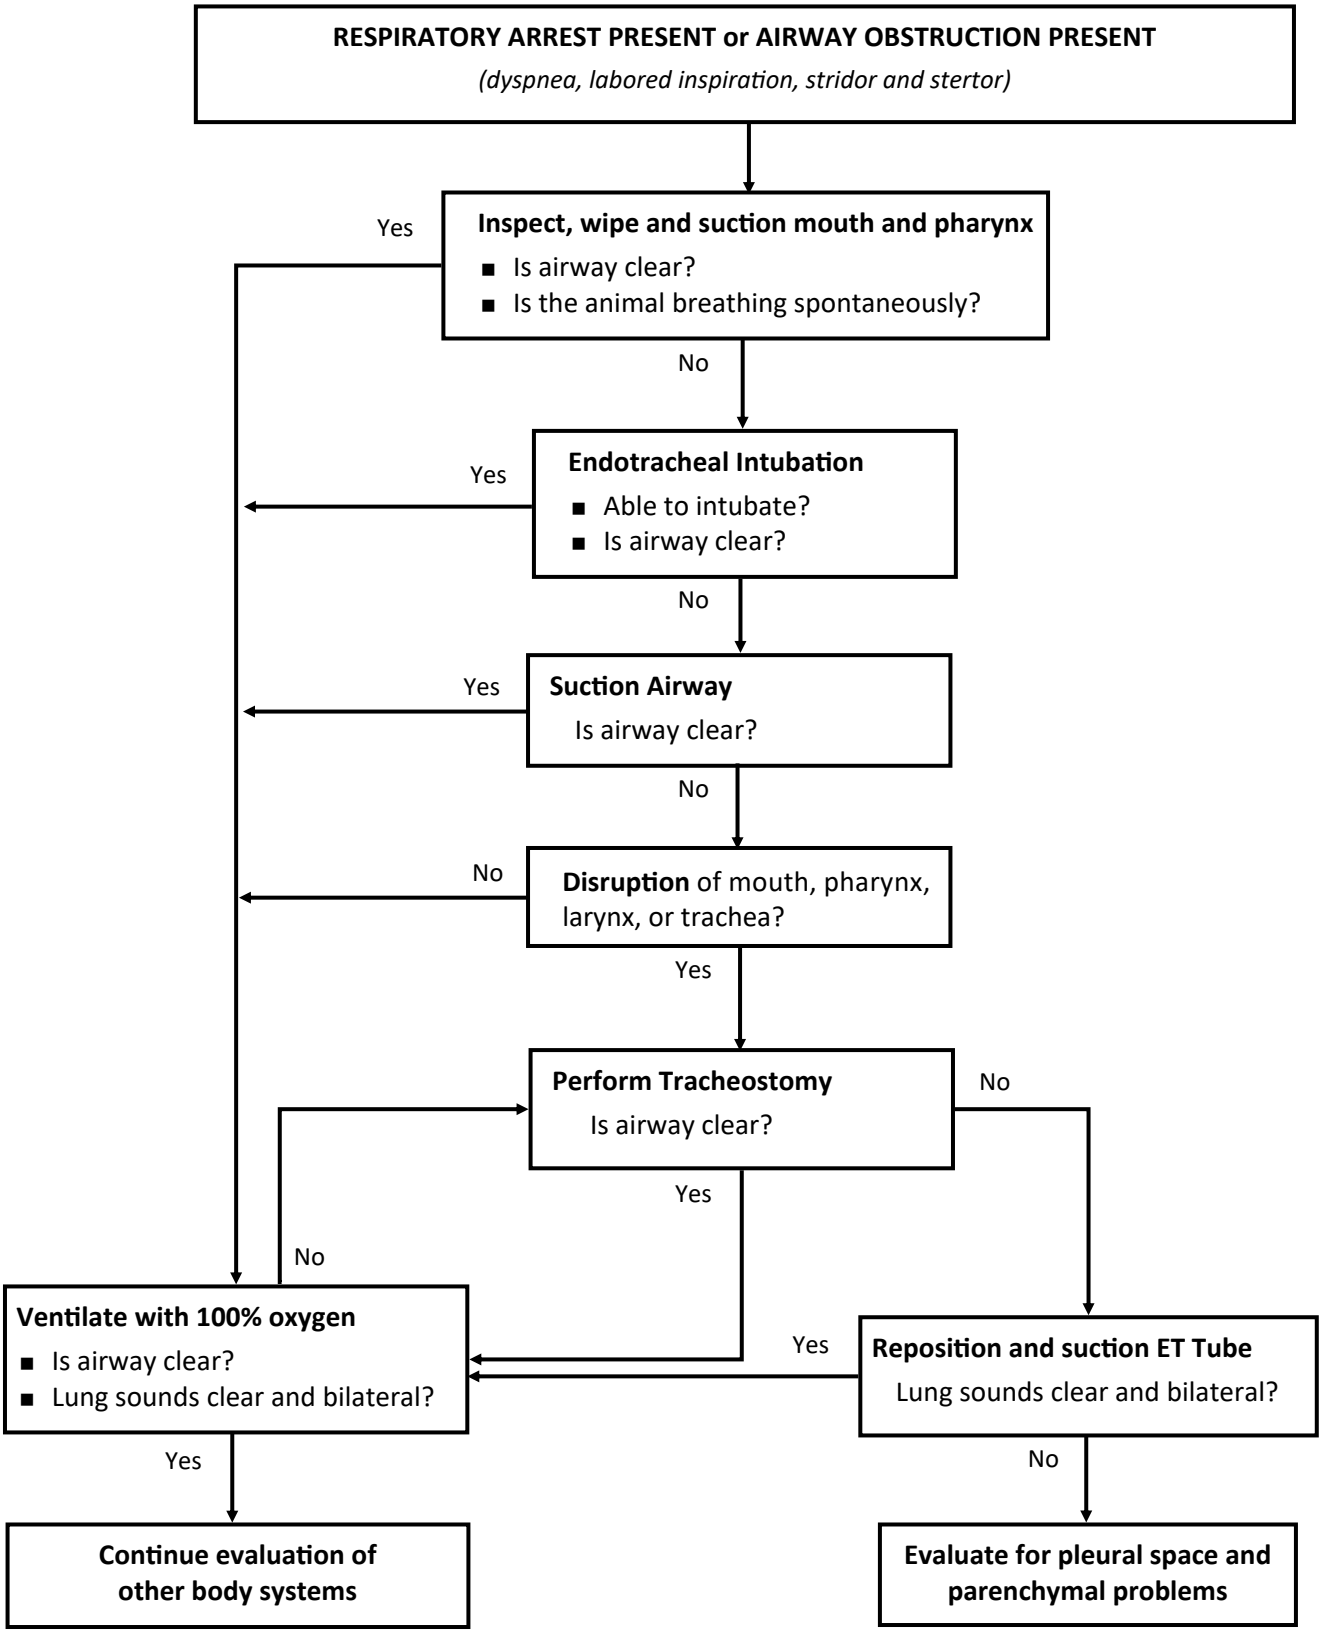
1. Provide oxygen therapy as above.
2. Bypass the obstruction until the patient is more stable:

    1) Attempt to remove the obstruction quickly by sweeping the mouth and pharyngeal area with a finger or gauze, suction the area, or use large forceps to remove objects that may be obstructing the passage.

    2) Do not attempt a Heimlich maneuver unless you know the object is smooth (e.g., ball); most trauma patients do not have a smooth foreign body obstruction, and the maneuver can cause significant patient distress and possibly further injury.

- If the obstruction cannot be removed in a few seconds, consider tracheal insufflation with oxygen for immediate oxygen delivery (See Table 4 for technique), and perform an emergency tracheostomy (See Table 5 for technique.
- Patient anxiety is frequently a compounding factor; tranquilize, sedate, or anesthetize if necessary.
- Management of patients with tracheostomy tubes requires 24-hour care and observation. Perform tracheal and pulmonary toilet as for human patients. Perform local wound care at least every 12 hours. Tube dislodgement is a potentially life-threatening complication that must be guarded against and monitored.

Figure 25. Airway Obstruction Management Algorithm for MWDs.



Tracheal Insufflation with Oxygen

TABLE 4. TRACHEAL INSUFFLATION WITH OXYGEN FOR MWD TECHNIQUE[6]
1. Clip hair and surgically prepare a 6 inch X 6 inch area of the ventral neck area just distal to the larynx.
2. For conscious MWDs, sedate and use 20 mg lidocaine locally.
3. Attach a 10 mL syringe to the hub of a 14 or 16 gauge, 6 inch, over-the-needle catheter.
4. Stabilize the trachea with one hand.
5. While holding the catheter-syringe apparatus at a 45° angle, direct the catheter through the skin and annular ring between the 3rd and 4th or 4th and 5th tracheal cartilages, directed ventrally down the trachea. Do not pass through the cricothyroid membrane in dogs.
6. Begin to slowly aspirate with the syringe as you pass the catheter through skin.
7. Once the tip of the needle is through the skin, aspiration of air signifies successful entry into the tracheal lumen.
8. Once the catheter is successfully introduced into the tracheal lumen, stabilize the needle to prevent any further advancement of the needle into the trachea.
9. Advance the catheter OFF the needle, directed down the trachea, until the hub of the catheter is in contact with the skin.
10. Remove the needle from the catheter.
11. Attach oxygen tubing to hub of catheter and provide high-flow oxygen (10-15 L/min).
12. Do not use this method for more than 30-45 minutes, as hypercapnia will develop and lung barotrauma may occur due to high airway pressures. Use tracheal insufflations as a “bridge” to more practical methods (e.g., orotracheal intubation, tracheostomy).

Emergency Tracheostomy

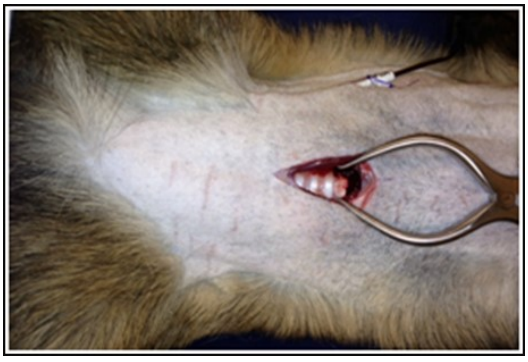
TABLE 5. EMERGENCY TRACHEOSTOMY OF MWD TECHNIQUE[6]

1. Position the animal in dorsal recumbency if unconscious, sedated, or anesthetized, extend the neck, and place a rolled towel or sandbag under the neck to force the trachea upwards. In conscious MWDs, position the MWD in sternal recumbency and extend the head upward to expose the ventral neck; sedate the dog and locally anesthetize the incision site with 20 mg lidocaine.

2. Clip the hair over the center of the ventral neck from the larynx to approximately the center of the neck, and prep the skin with surgical disinfectant.

3. Make a full-thickness, ventral midline skin incision 2-3 finger widths below the larynx (ideally over the 3rd to 5th cartilage rings) parallel with the long axis of the trachea. Do NOT make a transverse skin incision (perpendicular to the long axis of the trachea), as this increases the risk of injury to adjacent vessels and nerves.

4. Separate the muscle bellies overlying the trachea using sharp or blunt dissection. Place a Gelpi or Weitlaner retractor to spread the muscle bellies and allow visualization of the trachea.



5. Stabilize the trachea with the non-dominant hand.

TABLE 5. EMERGENCY TRACHEOSTOMY (CONTINUED)

6. Make a transverse incision completely through the annular ligament between the 3rd and 4th or 4th and 5th tracheal cartilages to create the tracheostomy. Do NOT extend the incision more than one-half (50%) of the diameter of the trachea. Do NOT incise at the cricothyroid ligament, as is done in people.

7. Using a cricothyroidotomy hook or stay sutures, retract the lower tracheal ring to open the tracheal lumen.

8. Insert a tracheostomy tube (ideal) or endotracheal tube through the incision and direct the distal opening down the trachea. Use the largest tube that will fit in the trachea; 7-11mm internal diameter tubes are typical.

9. Once the tube has been inserted, place long stay sutures around the cartilage rings above and below the tracheostomy. These allow rapid control of the airway should the tube become dislodged, and facilitates tube maintenance.

10. Secure the tracheostomy tube to the patient using umbilical tape, roll gauze, or similar material tied to the wings of the tube and passed around the neck and tied with a quick release knot. Do NOT suture the tube to the skin, as it cannot be removed rapidly if it obstructs.

11. Insert the inner cannula (if provided) in the tracheostomy tube (if used) and inflate the cuff of the tracheostomy tube.

Orotracheal Intubation

TABLE 6. OROTRACHEAL INTUBATION OF MWD TECHNIQUE[6]
1. Typical MWD needs a 9-11 mm internal diameter cuffed endotracheal tube.
2. Premeasure intended insertion length by placing the tube alongside the extended head and neck of the dog. Locate the larynx and position the cuff just below it. With the tube still lined up along side of the head and neck and the cuff positioned just below the larynx, apply a piece of tape to the tube opposite the lower canine teeth or incisors as a depth indicator when inserting the tube.
3. Cut and tie an 18 to 24 inch length of roll gauze to the end of the tube with the tape on it.
4. Lightly lubricate the cuffed end of the tube with sterile lubricant.
5. Place the MWD in sternal recumbency.
6. Have the handler lift and extend the dog's neck with one hand holding the upper jaw and the other hand holding the back of the head. Rolling the upper lips away improves visibility.
7. Grasp the animal's tongue with a dry 4X4 gauze sponge and gently pull the tongue out and down between the lower canine teeth.
8. Holding the laryngoscope in the other hand, place the tip of the blade on the base of the animal's tongue near the epiglottis and apply gentle downward pressure on the tip of the laryngoscope blade to visualize the opening to the trachea. 9. Transfer the laryngoscope to the hand holding the animal's tongue.

10. With the free hand, using a slight rotating motion, guide the tube over the epiglottis, between the vocal cords, through the laryngeal opening, into to the trachea.

11. Advance the endotracheal tube into the trachea until the tape marker reaches the landmark.

12. Verify endotracheal tube placement.
    a. Palpate the dog's neck and feel for 1 tube. If 2 tubes are felt, the endotracheal tube is in the esophagus (1 "tube" is the trachea and the other is the endotracheal tube in the esophagus). Remove the tube and attempt intubation again if 2 tubes are felt.
    b. Place the base of the laryngoscope at a 90 degree angle next to the end of the endotracheal tube and look for fogging of the base caused by the animal exhaling air through the endotracheal tube. If fogging is noted, the tube is likely correctly placed.
    c. Attach a capnometer (if available) to the endotracheal tube and measure E_TCO_2. If E_TCO_2 is measured >10 mmHg, the tube is correctly positioned.

13. Inflate the cuff with the syringe until back pressure is noted in the syringe. Check for leaks and normal lung sounds during assisted ventilation.

14. Secure the tube into place by securing the attached roll gauze behind the canine teeth. Tie the gauze using a bow knot around the upper or lower jaw of the animal.

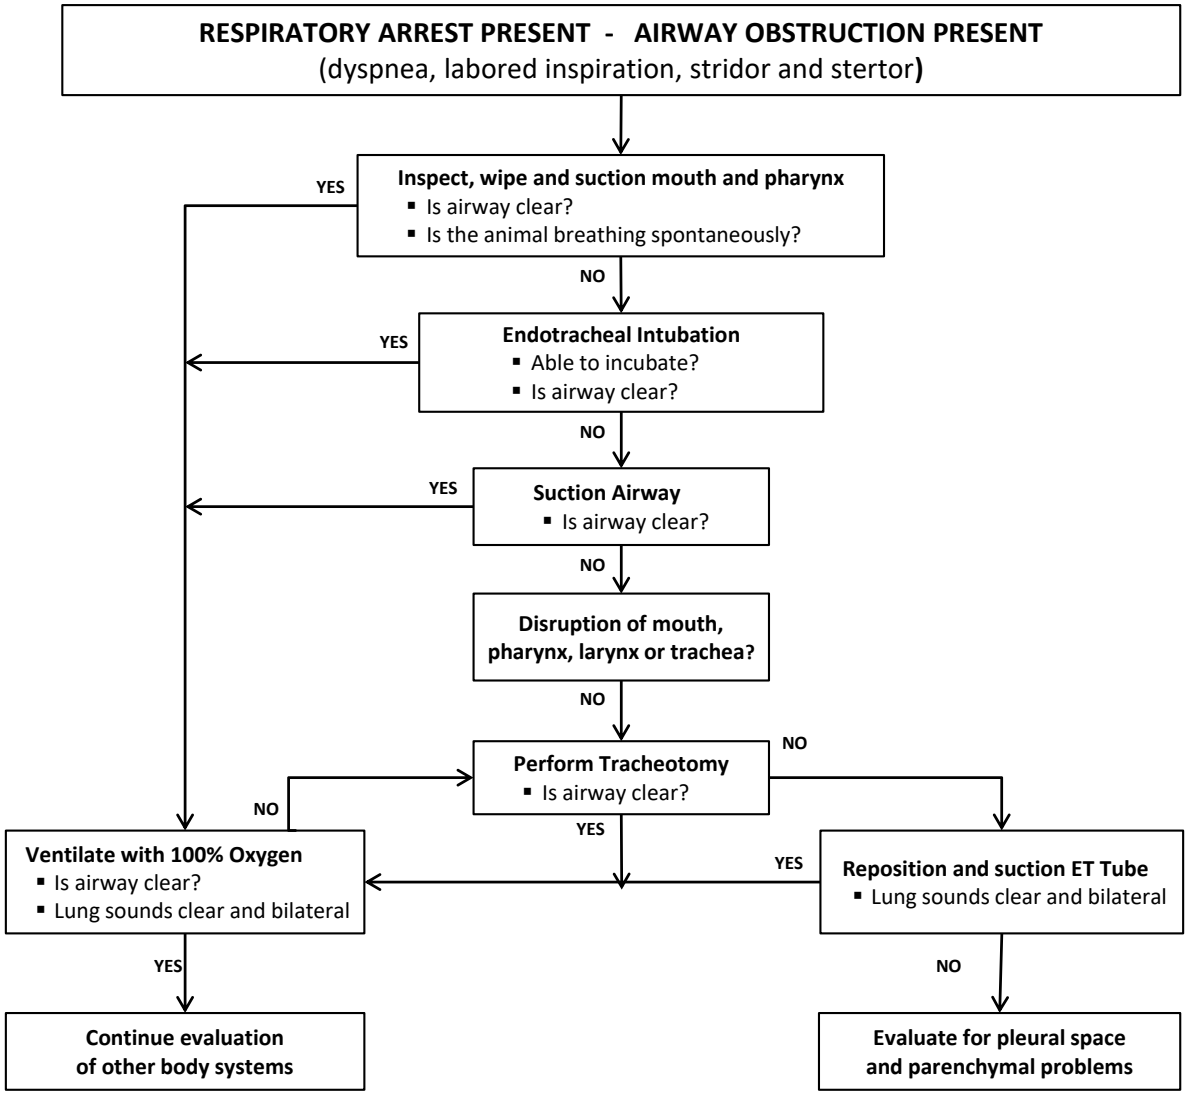
Penetrating Chest Wounds & Respiratory Distress

Respiratory distress develops in deployed MWDs most commonly due to trauma. MWDs in respiratory distress are fighting to get oxygen: they are anxious, usually have obvious problems breathing, usually have their head and neck extended, elbows and upper legs held out from the chest, don't want to lie down, and fight restraint and handling. Cyanosis, if present, is a late finding.

MWDs in respiratory distress typically have 1 of 3 characteristic breathing patterns that help localize the problem. A clinical algorithm for differentiating the most likely cause of a patient's distress based on the pattern of breathing is provided (See Figure 26).

Provide supplemental oxygen for any dog in respiratory distress (See Chapter 3).

Figure 26. Clinical Algorithm for Differentiating Cause of Distress Based on Breathing Pattern.[1]



Thoracic Radiography and Thoracic Focused Assessment with Sonography in Trauma (TFAST)

Thoracic radiography and TFAST exams are useful adjunct procedures, especially in the diagnosis and treatment of pneumothorax, hemothorax, pleural effusion, pulmonary contusions, or pulmonary edema. Radiography is also appropriate for documentation of correct thoracostomy tube placement.

Perform thoracic radiography on every traumatized MWD, if available, even if there is no clinical evidence of thoracic trauma. A significant number of trauma patients without outward evidence of chest trauma have hidden trauma that may manifest later, complicate management, or worsen with treatment of other conditions.

TFAST should be performed on every MWD that presents with a history of trauma, if the HCP has significant experience in its use; TFAST requires a high degree of experience to optimize diagnostic reliability. As with human casualties, TFAST is sensitive and specific for the diagnosis of pneumothorax and pulmonary parenchymal fluid, and for rapidly evaluating for pericardial and pleural effusions.[4] Figure 27 shows the imaging locations for TFAST in the dog. Figure 28 describes a clinical management algorithm for the use of TFAST in dogs.

Figure 27. Imaging Locations for TFAST.[4]
Figure 27 shows the ultrasound probe locations for TFAST in the dog.

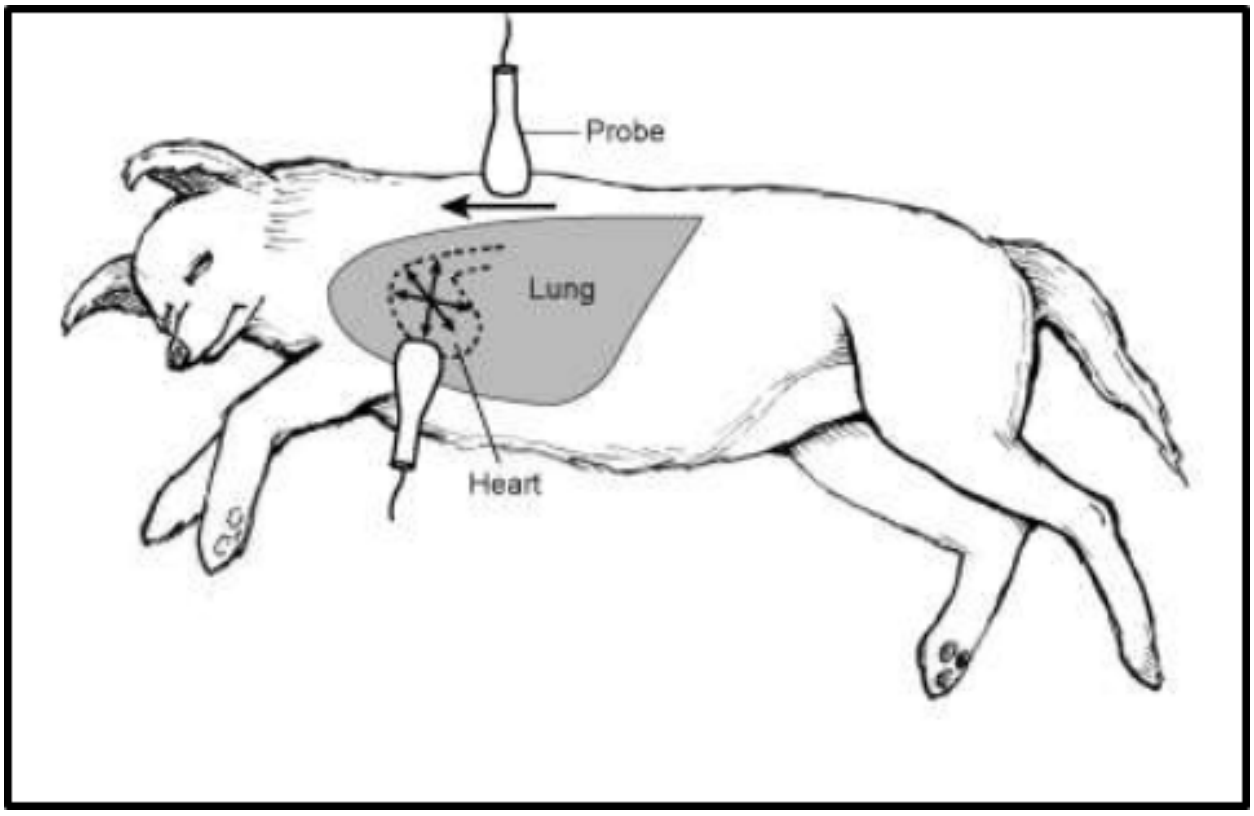


Figure 28. Clinical Management Algorithm for TFAST Use in Military Working Dogs.[4]

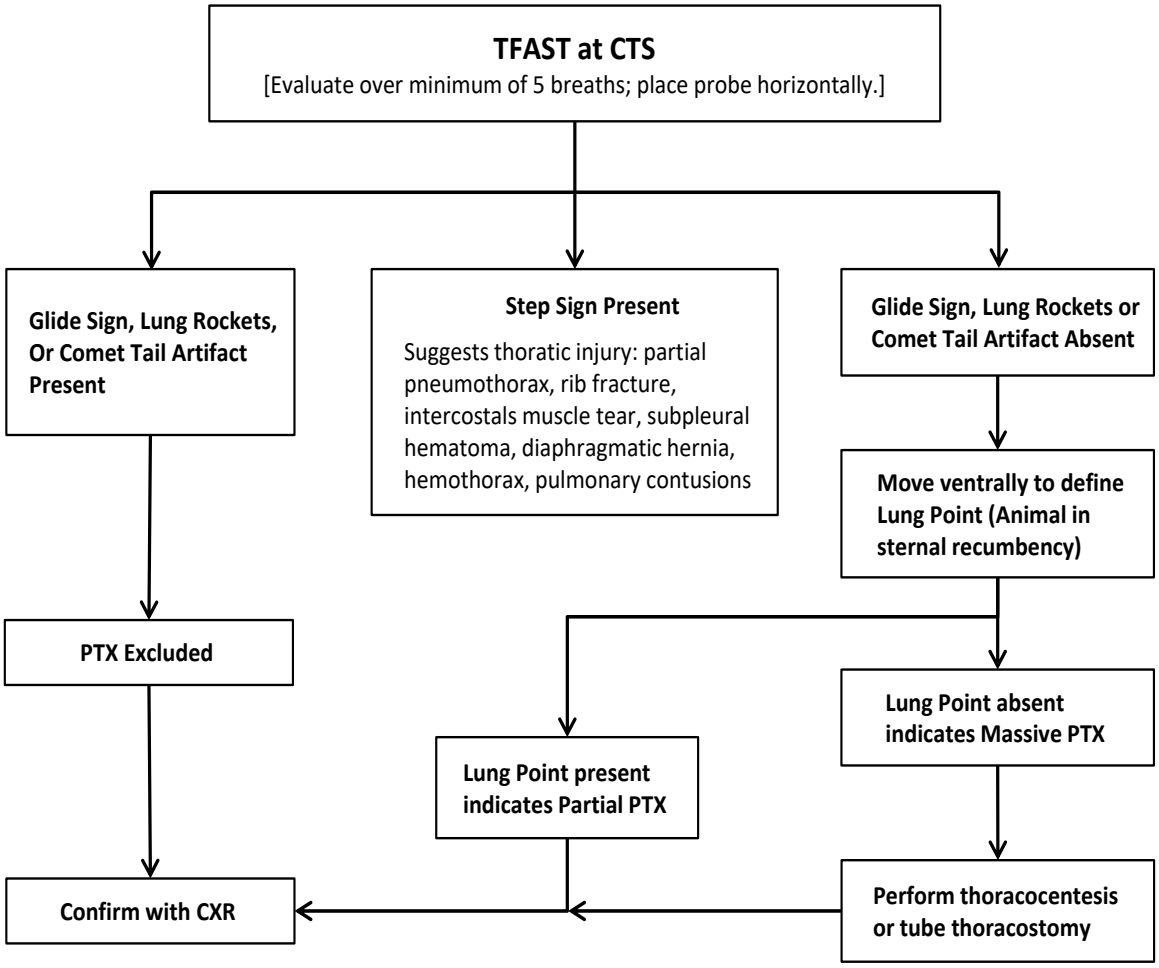


TFAST at CTS
[Evaluate over minimum of 5 breaths; place probe horizontally.]
Glide Sign, Lung Rockets, Or Comet Tail Artifact Present
Step Sign Present
Suggests thoratic injury: partial pneumothorax, rib fracture, intercostals muscle tear, subpleural hematoma, diaphragmatic hernia, hemothorax, pulmonary contusions
Glide Sign, Lung Rockets or Comet Tail Artifact Absent
Move ventrally to define Lung Point (Animal in sternal recumbency)
PTX Excluded
Lung Point absent indicates Massive PTX
Lung Point present indicates Partial PTX
Confirm with CXR
Perform thoracocentesis or tube thoracostomy

Note: CTS refers to probe imaging location at the conventional Chest Tube Site (8th-11th intercostal space). PTX refers to pneumothorax. CXR = thoracic radiography.

Thoracic Injury

Up to 50% of traumatized dogs have some form of thoracic injury.[5-12] Pneumothorax (PTX) and pulmonary contusions are very common. Dogs with thoracic injury typically have restrictive and parenchymal breathing patterns (See Figure 26).

Rib Cage Trauma

This includes flail chest, rib fractures, intercostal muscle rupture, and penetrating wounds. Signs mimic pleural space injury (restrictive breathing pattern). Usually the defect is obvious, especially if paradoxical chest wall motion is noted.

- Adequate management usually involves careful handling, laying the patient with affected side down, minimizing restrictive chest bandaging, and providing analgesia. External splinting or surgical management is usually not necessary unless injury is severe or extensive, or the chest wall is compromised and prolonged interference with gas exchange and ventilation is evident.
- Pain can substantially interfere with gas exchange and ventilation. Alleviate pain once the patient is stabilized to improve oxygenation and ventilation. Systemic or local analgesia are acceptable options (See Chapter 16). Local nerve/rib blocks and intrapleural analgesia administration work well and are readily accomplished.

Pleural Space Trauma

This includes PTX (open, closed, tension), hemothorax (HTX), and diaphragmatic hernia. A restrictive breathing pattern is the classic presentation—shallow, rapid respiration with muffled lung and/or heart sounds. Auscult the chest for decreased lung sounds over most of the thorax, which suggests either fluid (blood) or air in the pleural space, pulmonary contusions, or diaphragmatic hernia.

- Open PTX requires immediate action. Rapidly clip hair from around the wound, and apply any occlusive seal over the wound. Apply a chest bandage to secure the material. Delay wound closure until the MWD is stable. Open PTX always requires chest decompression after closure of the wound.
- The presence of decreased lung sounds in a trauma patient with signs of respiratory distress, or rapid clinical deterioration in a MWD with respiratory distress is sufficient justification for needle thoracocentesis.
- Thoracocentesis is readily and rapidly accomplished, and safe when performed properly – "When in doubt, tap it!" Figure 29 on the next page shows the location for needle thoracocentesis in dogs.[13] See Table 8 for thoracocentesis technique in MWDs.
- The mediastinum in dogs is thin and typically ruptures; therefore, ***always tap both sides of the chest***, even if a positive tap is achieved on one side of the chest, as air will form pockets and will migrate.
- Repeated thoracenteses may be required to stabilize the patient. A negative chest tap doesn't always mean there's not an abnormal accumulation of air or fluid in the pleural space – it may mean you just couldn't find it! "When in doubt, tap it again!"
- In dogs, the intercostal artery, vein, and nerve run on the caudal aspect of each rib; thus, the best approach is by inserting the needle or catheter in the center of the intercostal space or at the cranial aspect of a rib.

Figure 29. Location for Needle Thoracocentesis.

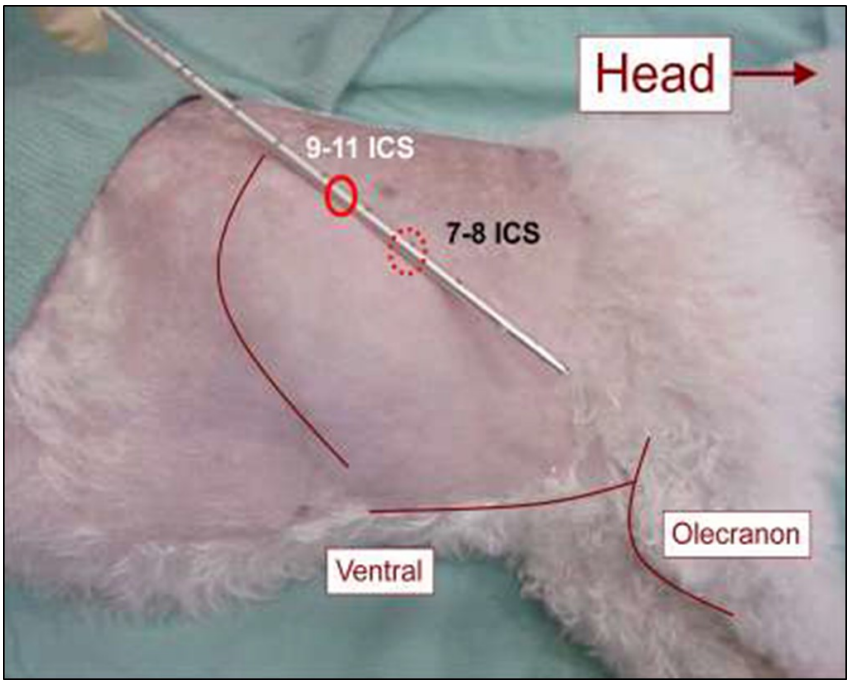
Figure 29 shows anatomic location for needle thoracocentesis in dogs, with the dog in lateral or sternal recumbency, and the needle inserted generally on the mid-lateral thorax between the 6th to 8th intercostal space. Count forward from the last rib (#13; red dotted line) to find the insertion site.

Immediate placement of a thoracostomy tube is indicated if negative pressure cannot be achieved with needle thoracocentesis, if large amounts of blood are aspirated, or if repeated thoracocenteses are required to maintain negative pleural pressure.

- A general rule of thumb for thoracostomy tube sizes is the chest tube should be the largest size that comfortably fits in the intercostal space. For most MWDs, use fenestrated tubes that are 24-36 Fr. Figure 30 shows the correct anatomic orientation for chest tubes placed in dogs. Table 9 describes techniques for chest tube placement in MWDs.
- Tube thoracostomy is a painful procedure. In emergent or critically ill patients, local analgesia may not be necessary. Consider local anesthesia, intercostal nerve blocks, and intrapleural analgesia in all other patients (See Chapter 16).
- Remove chest tubes when air or fluid accumulation is less than 2-4 mL/kg body weight per day.
- The chest tube will ideally lie in the pleural space, generally oriented cranioventrally to maximize removal of air and fluid. It is best to pre-measure the tube visually before placement to ensure proper depth of insertion. Be certain the last fenestration of the tube will be within the chest cavity.
    - Patients with chest tubes in place MUST be monitored continuously!
    - Some form of removal of air or fluid must be used. This can be continuous suction or intermittent aspiration by personnel.

Figure 30. Anatomic Orientation for Chest Tube Placement.

Figure 30 shows correct placement of a chest tube on the lateral aspect of the chest in a dog, with the tube penetrating the skin at the 9th to 11th intercostal space (ICS), tunneling cranioventrally to penetrate the chest wall at the 7th to 8th ICS, directed toward the olecranon of the elbow. Photo courtesy of Dr. Tim Hackett.



Resuscitative Thoracotomy

- Emergent thoracotomy may be indicated, keeping in mind caveats discussed previously.
- Thoracotomy in dogs is generally best done through a LEFT lateral thoracic wall approach, generally at the 4th to 5th or 5th to 6th intercostal space to afford optimal visualization. A median approach is not recommended in MWDs, given difficulties in post-operative management.
- Euthanasia should be considered for a MWD for which a resuscitative thoracotomy is deemed necessary but cannot be performed or has proven unsuccessful (See Chapter 21).

Parenchymal Trauma

Pulmonary contusions and intrabronchial hemorrhage are common. A restrictive breathing pattern may be noted in patients with mild and moderate parenchymal injury. Patients with severe parenchymal injury often have a parenchymal pattern, seen as respiratory distress with labored inspiration and expiration, with or without hemoptysis.

- Auscult the chest for decreased lung sounds, which suggest either fluid (blood) or air in the pleural space, or pulmonary contusions. A patchy distribution of altered lung sounds may be noted, which helps differentiate parenchymal injury from pleural space trauma.

- A negative thoracocentesis suggests the presence of pulmonary contusions in patients with these clinical signs. Note that radiographic signs (mixed interstitial-alveolar pattern) may lag 12-24 hours, and the stress of the process is usually not warranted.
- Hemoptysis, especially of arterialized (bright red) blood suggests significant large pulmonary vessel trauma that typically carries a very guarded prognosis.
- Most MWDs with pulmonary contusions do not require mechanical ventilation. Management of pulmonary contusions involves minimizing stress, providing oxygen supplementation, cautious intravenous fluid administration to prevent progression of contusions and/or development of pulmonary edema, and possible addition of colloids to the fluid therapy plan to decrease the amount of lung water that may accumulate during shock resuscitation. Diuretics and steroids are not indicated in treatment of pulmonary contusions, and may increase patient morbidity and mortality.
- Severe, life-threatening major pulmonary vessel hemorrhage may require resuscitative thoracotomy. Refer to the discussion of **Resuscitative Thoracotomy** in this chapter for guidance and technique.

Diaphragmatic Hernia

Auscultation of borborygma over the area of the lung field suggests the presence of a diaphragmatic hernia, but can be misleading. Standard radiography and ultrasonography procedures are diagnostic. Assume a hernia is present, and carefully manage the patient to minimize discomfort and further organ herniation until the patient is stable enough to allow definitive diagnosis of the hernia.

- ***Diaphragmatic hernia (DH) is usually not considered a surgical emergency unless the stomach is involved, or the patient's condition deteriorates or fails to respond to conservative management.*** In most cases, the patient should be stabilized for shock and other organ injury, with definitive repair of the hernia at a later time. Most patients suffering trauma severe enough to rupture the diaphragm have other pulmonary injuries that would preclude anesthesia and intermittent positive pressure ventilation (IPPV) (e.g., contusions, pneumothorax).
- Emergent repair of a DH may be indicated. Repair is performed via a cranial ventral midline laparotomy, with retraction of the liver and stomach caudally, to afford optimal visualization.
  - Some means of positive pressure ventilation is necessary intraoperatively.
  - At least 1 thoracostomy tube should be placed intraoperatively and maintained for at least 24 hours post-operatively to manage pneumothorax.
  - Generally, rents in the diaphragm due to trauma occur in the muscular portions of the diaphragm, and are readily repaired using a simple continuous suture closure.

Ventilatory Support

Ventilatory support (e.g., manual IPPV or mechanical ventilation) may be required for dogs that fail to respond to correction or stabilization of the primary respiratory problem and supplemental oxygen support.[15] Ventilatory support requires a heavily sedated or anesthetized patient, even if a tracheostomy tube is in place (See Chapter 16).

- Manual intermittent positive pressure ventilation (MIPPV) is feasible if personnel can be spared for this, and is ideal for short-term (i.e., <6 hours) of ventilator support.
- There may be instances in which mechanical ventilation (MV) is necessary to afford a chance for patient survival. MV may be necessary if MIPPV fails or duration of ventilator support is expected to be >6 hours. Providers must note that MV should be considered only if the provider has the necessary advanced MV training and experience, the provider feels there is a reasonable likelihood of success, and the provider has the necessary support staff, facilities, and monitoring and intensive care facilities to manage a MWD on MV without compromising human patient care. Thus, MV should be considered only in Level 2 or higher medical facilities and by trained specialists with adequate staff.
- Generally, it is best to induce general anesthesia and initially manage the ventilated dog using Controlled Ventilation or Assist-Control ventilator mode. Key ventilator settings are shown (See Table 7).

TABLE 7: MECHANICAL VENTILATOR SETTINGS & KEY PARAMETERS[13]

PARAMETER	NORMAL LUNGS	ABNORMAL LUNGS
F_IO_2	100%, then reduce to <60%	100%, then reduce to <60%
Tidal Volume (V_T)	5 – 15 mL/kg	5 – 15 mL/kg
Breathing Rate (f)	8 – 20 bpm	8 – 20 bpm
Minute Ventilation (V_E)	150 – 250 mL/kg/min	150 – 250 mL/kg/min
Peak Inspiratory Psi (PIP)	10 – 20 cmH_2O	15 – 25 cmH_2O
Positive End-Expiratory Psi (PEEP)	0 – 2 cmH_2O	2 – 8 cmH_2O
Trigger Sensitivity	-2 cmH_2O or 2 L/min	-2 cmH_2O or 2 L/min
Inspiratory: Expiratory Ratio (I:E)	1:2	1:2
Inspiratory Time	~ 1 sec	~ 1 sec

TABLE 8. NEEDLE THORACOCENTESIS OF MWDS[14]

1. Position the animal in sternal recumbency if conscious or lateral recumbency if unconscious, sedated, or anesthetized.
2. Clip the hair from and surgically prepare a 6 inch X 6 inch square area of skin on the mid-lateral aspect of the thorax centered between the 6th to 8th ribs.
   - If pneumothorax is suspected, prepare the thoracenteses sites at the junctions of the upper 1/3rd and lower 2/3rds of the thoracic wall.
   - If pleural effusion is suspected, prepare the thoracenteses sites at the costochondral junctions.
3. In conscious MWDs and if time, infiltrate 1 mL of local anesthetic (20 mg lidocaine or 5 mg bupivacaine) in the skin to the pleura.
4. Assemble an emergency thoracocentesis set. For a tension PTX, a 1-1.5 inch, 16-18 gauge over-the-needle catheter is sufficient to relieve tension. For other types of PTX, use a 1-1.5 inch, 18 gauge over-the-needle catheter, to which sterile extension tubing and a stopcock and 60 cc syringe are attached; this allows aspiration of air and fluid without iatrogenic PTX. ***Do NOT use the standard Needle Decompression Device (3.25 inch, 16 gauge), as risk of cardiac or pulmonary vessel trauma is high.***
5. Hold the needle with the thumb and index finger of one hand and brace the hand on the lateral aspect of the thorax by firmly resting the "knife" of the hand on the thorax near the proposed thoracocentesis site.
6. Hold the syringe in your dominant hand, or have an assistant manipulate the syringe and stopcock while you manipulate the needle. The syringe should be empty and the stopcock closed to room air.
7. While stabilizing the hand holding the needle, insert the needle at the proposed thoracocentesis site through the skin, intercostal muscles, and parietal pleura until ½ the length of the needle has been inserted.
8. While stabilizing the depth of the needle with your non-dominant hand, aspirate with the syringe plunger in an attempt to remove air or fluid.
9. If you are successful in removing air or fluid, close the stopcock to the patient and expel the contents from the syringe through the stopcock without removing the needle from the pleural space or breaking aseptic technique.
10. Repeat until no further air or fluid can be removed.
11. If you are not successful in removing air or fluid, insert the needle to the hub while aspirating with the syringe, or redirect the needle cranially, caudally, dorsally and ventrally, or do both in an attempt to tap a pocket of air or fluid.
12. If you are still unsuccessful in removing air or fluid, completely remove the needle from the thorax and attempt thoracocentesis in an intercostal space cranial or caudal to the initial site.

TABLE 9. TUBE THORACOSTOMY OF MILITARY WORKING DOGS[15]

1. Clip the hair from and surgically prepare an area of skin from the 4th to the 12th rib, and from the dorsal midline to the ventral midline.

2. Infiltrate local anesthetic (20 mg lidocaine +/- 10 mg bupivacaine) at the proposed skin incision site between the 9th and 11th intercostal space at the junction of the upper 1/3rd and the lower 2/3rds of the lateral thorax. Continue infiltration of the subcutaneous tissues cranioventrally to the intercostal space at the intended site of penetration of the thoracic wall between the 6th and 8th intercostal space. Infiltrate the intercostal muscles, down to the level of the parietal pleura.

3. Make a skin incision with a #10 scalpel blade that is the same diameter as the thoracostomy tube. Note that an incision that is too large increases the risk of iatrogenic PTX and fluid leakage.

4. Insert the thoracostomy tube using either a trocar or forceps through the skin incision and advance the tube cranioventrally toward the intercostal space where you intend to penetrate the thorax. This creates a subcutaneous tunnel and orients the tube to lie in the intended direction in the chest.

   Note: *The interval between the skin incision and the intercostals space where the tube penetrates the thorax must be at least 2 intercostal spaces in width to allow sufficient creation of a subcutaneous tunnel that is important in minimizing iatrogenic PTX and fluid leakage.*

   Note*: MWDs rarely develop pleural adhesions, so digital exploration before tube placement is not necessary.*

   Trocar Technique: (RECOMMENDED technique)

   1) Insert the tip of the tube through the skin incision and advance the tube subcutaneously cranioventrally at least 2 intercostal spaces. Be sure to hold the trocar firmly in the tube.
   2) Firmly drive the tip of the stylet into the intercostal musculature as you raise the thoracostomy tube vertically so that the tube is almost perpendicular to the thorax.
   3) This movement will cause the skin to bunch over the intercostal space and will expose the distal part of the tube that was in the skin tunnel.
   4) Firmly grasp the distal-most part of the thoracostomy tube with one hand approximately 2 cm from the tip to prevent inadvertent over insertion of the trocar when advancing the tube in the next step. Note that this step is vital, as this hand acts as a “brake” to prevent lung and heart trauma as the tube is inserted.
   5) Using either a single, sharp blow to the proximal blunt end of the stylet or firm continuous downward pressure on the proximal blunt end of the stylet, penetrate the intercostal muscles and pleura to advance the tube into the pleural space approximately 2 cm.
   6) Once the tip of the thoracostomy tube has been inserted approximately 2 cm into the pleural space, lay the tube flat against the body wall AS YOU BEGIN TO ADVANCE THE TUBE in the pleural space cranioventrally toward the point of the elbow.
   7) As the tube is advanced, begin to slide the stylet out of the tube.
   8) Clamp the thoracostomy tube using the box lock of the Rochester-Carmalt or similar forceps as the stylet is removed to prevent pneumothorax.
   9) Close the proximal (outer) opening of the thoracostomy tube using either a Heimlich valve or tubing adapter and stopcock so that air does not enter the pleural space.

TABLE 9. TUBE THORACOSTOMY OF MWDS[15] (CONTINUED)

Forceps Technique: (NOT ideal; more traumatic and technically demanding)

1) Create a subcutaneous tunnel by bluntly advancing a 7" curved Rochester-Carmalt forceps or similar forceps (without the tube) cranioventrally from the skin incision site to the proposed intercostal space where the thoracostomy tube will penetrate the thorax.
2) Forcefully drive the tip of the forceps through the intercostal muscles and parietal pleura using a firm, quick thrusting motion, to enter the chest cavity.
3) While the tips of the forceps are inserted through the intercostal muscles and pleura, firmly open the jaws of the forceps to dilate the penetration site in the thoracic wall.
4) Remove the forceps and grasp the distal end of the thoracostomy tube with the jaws of the forceps such that the length of the tube is lying over the handles of the forceps. Just a small part of the tip of the tube should extend beyond the tip of the forceps.
5) Attach a Heimlich valve or clamp the thoracostomy tube BEFORE placing the tube to prevent pneumothorax.
6) Insert the forceps holding the tube through the skin incision and advance the tube and forceps cranioventrally through the subcutaneous tunnel to and through the intercostal opening.
7) Without removing the forceps, open the jaws of the forceps to release the thoracostomy tube. Advance the thoracostomy tube into the pleural space in a cranioventral direction toward the point of the elbow.
8) As the thoracostomy tube is advanced into the pleural space, slowly remove the forceps completely.
9) Continue to advance the thoracostomy tube until you are absolutely certain the most proximal fenestration of the tube is well within the pleural space, and is not in the subcutaneous tunnel or outside the skin.

5. Secure the chest tube to the skin using a horizontal mattress suture through the skin ventral to the skin tunnel, a purse string suture at the skin incision site that surrounds the tube where it enters the skin, and a "finger trap" suture around the tube anchored to the skin. Incorporate the chest tube in a bandage applied around the thorax to protect the tube.

CHAPTER 5

Cardiopulmonary Resuscitation (CPR)

Indications for CPR

HCPs should consider CPR of MWDs in cases of non-traumatic cardiopulmonary arrest (anesthesia-related, hypothermia, near drowning, electrocution). If the tactical situation and resources permit, HCPs may consider CPR in MWDs with CPA due to blast injury, blunt trauma, or penetrating trauma, although successful resuscitation in these cases is unlikely. Overall survival in dogs is approximately 5%.

Clinical Management Algorithm for CPR

In general, CPR is performed in much the same manner as for people.[1] Management guidelines for CPR in dogs are provided (See Figure 31 and Table 10).

Basic Life Support[2-4]

2-person, closed-chest CPR should be initiated as soon as CPA is declared.

- Circulation – Immediately begin sustained, forceful chest compressions with the MWD in lateral recumbency (on either side) at a rate of 100 compressions per minute. Sustain compressions for at least 2-3 minutes per cycle. Hand placement can be directly over the heart (where the elbow crosses the chest above the sternum when the forearm is pulled caudally) or over the widest part of the chest (See Figure 32). Ensure adequate relief of downward pressure during the relaxation phase of the compressions. As for people, "PUSH HARD and PUSH FAST."[1]

- Airway – Establish an airway as rapidly as possible and as soon as possible after identifying a patient in CPA. However, start chest compressions first! Intubate the MWD if possible; if intubation is not possible, perform an emergent tracheostomy without delay (See Chapter 2).

- Breathing – Ventilate the patient at a rate of 8-10 breaths per minute. Avoid hyperventilation. Give oxygen if available; room air is acceptable if oxygen is not available.

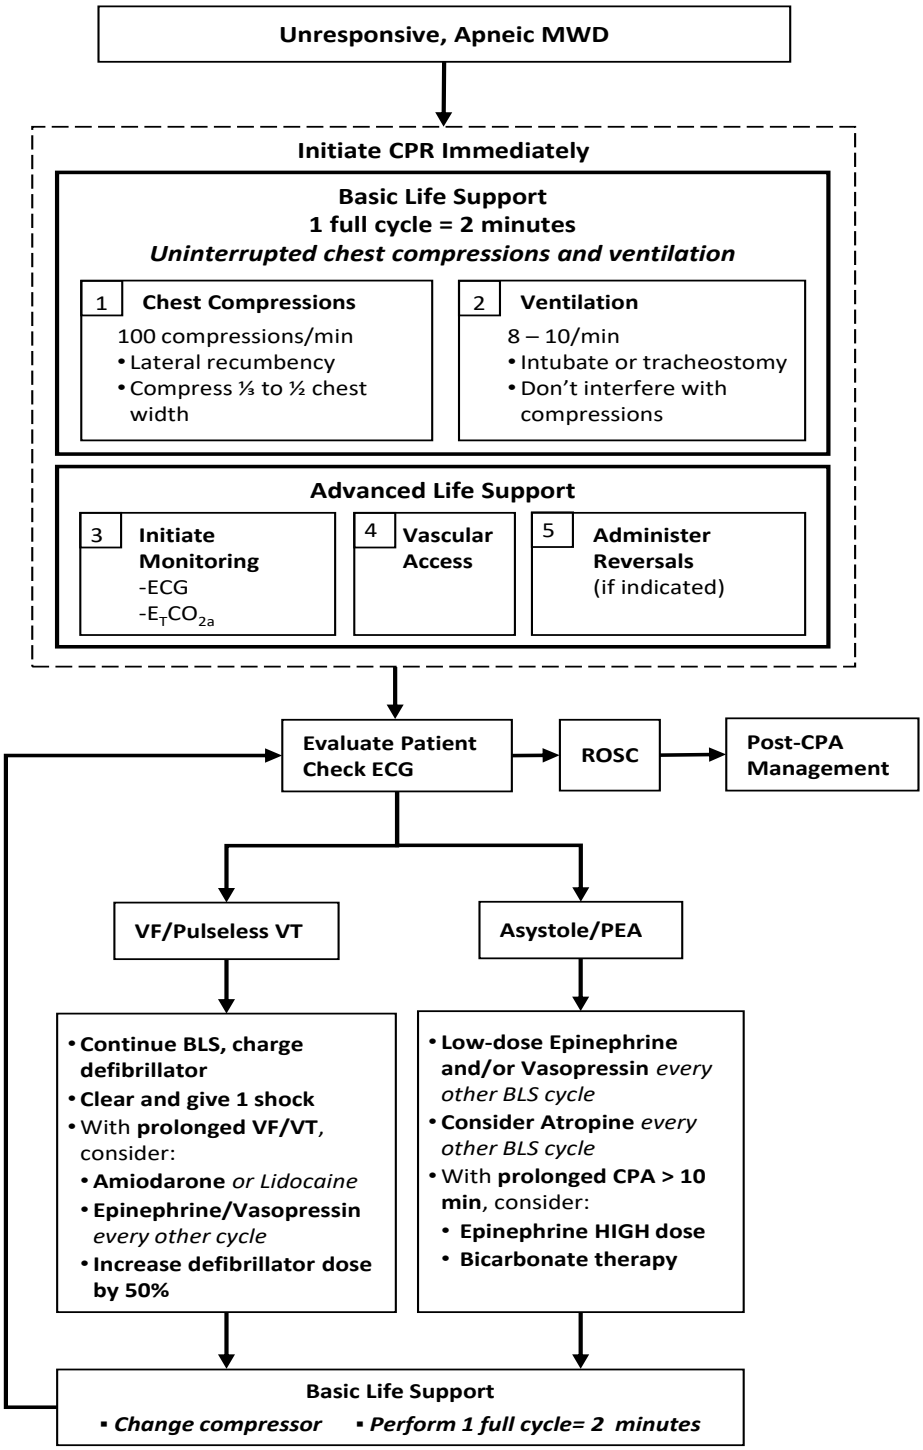
Figure 31. CPR Algorithm for Military Working Dogs.[2]



Clinical algorithm for canine cardiopulmonary resuscitation. Adapted from Cole SG, Otto CM, Hughes D. Cardiopulmonary-cerebral resuscitation in small animals–a clinical practice review, Part II. J Vet Emerg Crit Care 2003;13:1323. Used with permission

Advanced Life Support[5]

Initiate ALS as soon as feasible, with ECG monitoring to guide management. Figure 31[2] and Table 10 direct specific actions based on the arrest rhythm present. In contrast to people, the most common arrest rhythm in MWDs is pulseless electrical activity (PEA; 24%), followed by asystole (23%), and then ventricular fibrillation (VF; 20%). Sinus bradycardia commonly precedes arrest in many situations in dogs.[2,5]

- 70% of MWDs that arrest will have PEA, asystole, or sinus bradycardia as the initial arrest rhythm.[2,5] Epinephrine or vasopressin are best choices for these rhythms or for empiric use if ECG capability is not available. In the deployed setting, there is no role for transthoracic pacing in MWDs with PEA or asystole.
- Bradycardia due to a pronounced vagal response is very common in dogs, and use of atropine may prevent development of cardiopulmonary arrest.
- VF, while present initially in only 20% of MWDs with an arrest rhythm, often develops during resuscitation.[2] Perform external defibrillation if possible and as rapidly as possible if VF is noted; biphasic defibrillation is ideal.[5,7] Apply paddles to either side of the chest with the MWD in dorsal recumbency (on its back), or place a flat paddle under the MWD lying in lateral recumbency and a standard paddle on the upper chest wall. Defibrillate up to 3 times at each energy level if prior attempts are not successful, but perform aggressive chest compressions for at least 2 minutes before attempting each defibrillation.
- IV access is critical. Place multiple IV or IO catheters or perform venous cut-down (See Chapter 6, Figure 33). Follow all drugs with a 10 mL saline push. Do not give large volumes of fluids to MWDs during CPR, unless severe hypovolemia is thought present. Give fluids initially to facilitate drug delivery only.

Tips for Successful CPR in MWDS[2,3]

- Avoid interrupting chest compressions! The key to successful resuscitation is to SUSTAIN chest compressions aggressively for 2-3 minutes before stopping to check status.
- Most people apply too little force when performing chest compressions! Do not be concerned with breaking ribs or injuring the heart or chest with BLS. In contrast to CPR in people, the thorax of MWDs is more compliant and fractures are rare.
- Maintain a steady and continuous rate of chest compression and ventilation. Minimize the number of times you stop to check the patient. Most people stop too frequently, which makes BLS less successful.
- During CPR, consider sodium bicarbonate (1-2 mEq/kg IV, repeated every 10 minutes) if metabolic acidosis (pH <7.0) is present, or empirically if CPR is prolonged >10 minutes.
- During CPR, consider magnesium sulfate (30 mg/kg IV, once) in patients with refractory VT.

Single Person CPR

Single-person CPR on dogs is extremely challenging, with very poor success rates, and should be initiated only if other personnel are immediately nearby and can be mobilized to assist in 1-2 minutes. If single-person CPR is performed, the responder should only perform chest compressions, as this optimizes circulation.

Post-Resuscitation Care[6]

Resuscitated MWDs will require intensive care to optimize long-term outcome. Many MWDs will arrest again, and most do so in the first 4 hours after resuscitation.[2,3] Successful return of spontaneous circulation and resuscitation are unlikely if an MWD arrests again, and HCPs should balance resources against repeated attempts at resuscitation. Key management issues for MWDs in the post-resuscitation phase follow.

- Control seizures that develop with diazepam or midazolam (0.3 mg/kg; IV, IO, or intranasally), repeated every 15-30 minutes if necessary. If available, give phenobarbital (15 mg/kg IV or IO) loading dose, and 2.5 mg/kg IV every 12 hours thereafter if seizures persist or status epilepticus develops.
- Prevent and reduce cerebral edema. Use mannitol (1 gram/kg, IV, twice, 4-6 hrs apart), avoid hyperventilation, give a single dose of dexamethasone (0.5 mg/kg IV) or methylprednisolone sodium succinate (30 mg/kg, IV, once), avoid jugular vein compression, and maintain normoxemia and normotension.
- Maintain adequate ventilation, maintaining a patent airway and using manual IPPV at 8-10 breaths per minute, targeting an E_TCO_2 of 25-60 mmHg.
- Maintain adequate oxygenation, targeting a SpO_2 > 95% using supplemental oxygen for a minimum of 12 hours.
- Maintain normotension using IV fluids in bolus challenges, targeting a MAP > 65 mmHg or Sys > 90 mmHg. Isotonic crystalloids at 10-15 mL/kg over 15 minutes are usually effective.
- Use synthetic colloids if 2-3 bolus challenges do not achieve normotension. Give 2-3 bolus challenges of hydroxyethyl starch (HES) at 10 mL/kg over 15 minutes. Once normotension is achieved, give crystalloid IV fluids at 3-5 mL/kg/hour for maintenance. Given the dismal outcome in post-resuscitation MWDs that require vasopressor support, there is no role in the deployed setting for vasopressor therapy in MWDs in the post-resuscitation phase.
- Control pathologic ventricular arrhythmias with a lidocaine CRI (50-75 mcg/kg/min).
- Do not attempt tight control of blood glucose with insulin. Supplement IV fluids if hypoglycemia is present (5% dextrose), but avoid hyperglycemia.
- There is no role for therapeutic hypothermia in MWDs during the post-resuscitation period. Avoid hyperthermia; tolerate mild hypothermia (>92° F) if it develops.

Discontinuation of CPR

CPR should be discontinued 1) if the animal is successfully resuscitated, 2) if the senior HCP directs that efforts cease, or 3) if effective CPR has been attempted for at least 20 minutes without success.

Resuscitative Thoracostomy and Open-Chest CPR

There is no role for open-chest CPR by HCPs in MWDs. Euthanasia is indicated for any MWD for which a resuscitative thoracostomy is deemed necessary to manage CPR (See Chapter 21).

TABLE 10. MWD CPR PROTOCOL.[2-7]

BASIC LIFE SUPPORT		
Focus	**Actions**	**Comments**
CIRCULATION	IMMEDIATE chest compressions FAST and HARD -- 100/min	SUSTAIN for 2 minute cycles!
AIRWAY	Clear airway > Intubate or Tracheostomy	Don't interfere with compressions!
BREATHING	Manually ventilate (100% oxygen) 8-10 breaths/min	Don't hyperventilate!

ADVANCED LIFE SUPPORT

- ECG interpretation is essential
- Venous access is critical -- Place multiple peripheral lines and/or IO catheters -- Consider central line when able
- Follow all drugs with 10 mL saline push
- Do NOT give large volumes of fluids during CPR, unless the MWD is hypovolemic

ASYSTOLE, PEA, SINUS BRADYCARDIA		
Drugs	**Dose and Route**	**Comments**
VASOPRESSIN ***and*** EPINEPHRINE	0.8 U/kg -- IV or IO — ***ONCE!*** 0.01 mg/kg -- IV or IO	70% of arrests have these initial arrhythmias. These drugs are best for empiric use if ECG is not available, or if indicated by ECG.
…and…		
ATROPINE	0.04 mg/kg -- IV or IO ***only if bradycardia preceded arrest***	

VENTRICULAR FIBRILLATION or PULSELESS VENTRICULAR TACHYCARDIA		
ELECTRICAL DEFIBRILLATION	2 - 5 Joules/kg (biphasic) 4 – 6 J/kg (monophasic)	Only 20% of patients present initially with these arrhythmias. However, V Fib and pulseless V tach often develop during CPR.
	Immediately start compressions for 1 cycle after every defib attempt	
	Defibrillate TWICE more if needed at same energy level, BUT ***resume chest compressions for 1 cycle after each defib***	
…DRUG THERAPY if DEFIBRILLATION UNSUCCESSFUL…		
EPINEPHRINE	0.01 mg/kg -- IV or IO	Give SODIUM BICARBONATE every 10 minutes during CPR if pH is <7.0 or CPR is prolonged more than 10 minutes. **1-2 mEq/L, IV**
…or…		
VASOPRESSIN ***and*** LIDOCAINE	0.8 U/kg -- IV or IO -- ***ONCE!*** 2 mg/kg -- IV or IO	
…or…		Give MAGNESIUM SULFATE if patient has refractory VENTRICULAR TACHYCARDIA. **30 mg/kg, IV, once**
AMIODARONE	5 - 10 mg/kg -- IV or IO	
DEFIBRILLATE at 50% INCREASED energy if REFRACTORY		

TABLE 10. MWD CPR PROTOCOL.[2-7] (Continued)		
POST-RESUSCITATION MANAGEMENT		
▪ Maintain NORMOTENSION -- Target MAP of >65 mmHg or Systolic BP >90 mmHg ▪ Maintain VENTILATION -- Target RR of 8 - 10 bpm -- Target E_TCO_2 of 25 - 60 mmHg; consider IPPV/MV if needed ▪ Maintain OXYGENATION -- Target SpO_2 >95% with supplemental oxygen as needed		
CONTROL SEIZURES		
MIDAZOLAM or DIAZEPAM		0.3 mg/kg -- IV, IO, or INTRANASAL *prn*
MANAGE CEREBRAL EDEMA		
MANNITOL	1 - 2 grams/kg -- IV over 30 min	▪ Avoid HYPERVENTILATION ▪ Avoid JUGULAR VENOUS ▪ COMPRESSION ▪ Avoid HYPERTHERMIA ▪ Tolerate MILD HYPOTHERMIA
and		
DEXAMETHASONE	0.5 mg/kg -- IV -- ONCE	
…or…		
METHYLPREDNISOLONE	30 mg/kg -- IV -- ONCE	
CONTROL PATHOLOGIC VENTRICULAR ARRHYTHMIAS		
LIDOCAINE	CRI @ 50 - 75 mcg/kg/min	CORRECT H's and T's FIRST
CONTROL HYPOGLYCEMIA		
SUPPLEMENT IV fluids with 5% dextrose -- MONITOR blood glucose q4-6 -- AVOID intensive glucose titration

CHAPTER 6

Shock Management

Shock in deployed MWDs will most likely be due to hemorrhage from trauma or hypovolemia due to heat injury or gastrointestinal losses. Control bleeding (if present) and then stabilize the patient using targeted fluid therapy. Figure 33 provides a clinical management algorithm for shock management in MWDs.

Immediate Hemorrhage Control

Treatment by handlers and combat medics may have been performed, with varying degrees of success.[1,2] Expect dogs to arrive with pressure dressings, hemostatic gauze packed into wounds, and improvised tourniquets. Expect untreated or inadequately treated extremity hemorrhage, and suspect "hidden" intracavitary hemorrhage in the chest and abdomen.

- Assess for unrecognized hemorrhage and control all sources of external bleeding. Use direct pressure initially, or rapidly clamp and ligate major vessels if traumatized. Dogs have excellent collateral circulation, and paired major vessels can be ligated without concern for tissue ischemia or edema, to include the femoral arteries and veins, external jugular veins, external carotid arteries, and brachial arteries and veins.[3,4]
- Tourniquets are unreliable on the limbs of dogs due to the anatomic shape of the leg. Conventional human tourniquets do not remain in place or effectively control hemorrhage. Some success is reported in use of improvised tourniquets, such as surgical rubber tubing or constrictive gauze bandage. If delay in definitive care of major extremity trauma is expected, use hemostatic agents, direct pressure, and compressive bandaging to assist with hemorrhage control.
- Use thoracic FAST (TFAST) and abdominal FAST (AFAST) to rapidly scan for intracavitary fluid (See Chapter 4 and Chapter 7).[5,6] Assume intracavitary fluid is due to bleeding until proven otherwise.

Clinical Signs of Shock in MWDs[7,8]

Dogs in shock are amazing in how stable they appear on initial presentation, due to compensatory mechanisms.

- MWDs in early (compensatory) shock may have tachycardia, tachypnea, alert mentation, rapid arterial pulses with a normal or increased pulse pressure, decreased capillary refill time (< 2 seconds), and normal or bright red mucous membranes. While this MWD seems normal, it is already in compensatory shock. Immediate treatment at this point may stop the progression of shock.
- As the early decompensatory phase of shock begins, tachycardia persists, pulse pressure and quality begins to drop or may be normal, capillary refill time becomes prolonged, mucous membranes appear pale or blanched, peripheral body temperature drops, and mental depression develops. Aggressive treatment must be provided to halt ongoing shock.
- As late decompensatory shock develops, the heart rate drops despite a decreased cardiac output, capillary refill time is very prolonged or absent, pulses are poor or absent, both peripheral and core temperature is very low, and marked mental depression (stupor) is present. Irreversible cellular injury may be present to such a severe degree that despite aggressive measures at this point, many patients will die.

Standard Shock Therapy

Provide immediate fluid therapy targeted to specific endpoints, provide supplemental oxygen, and identify and treat the cause for the shock. Tranexamic acid (TXA) or ε-aminocaproic acid (EACA) may be helpful in dogs with catastrophic hemorrhage.

1. Place multiple large-bore IV or IO catheters or perform venous cut-down.

   - Do not delay in placing catheters. *The IO route is rapid, reliable and safe — USE IT!* Place peripheral or central lines when feasible. If one percutaneous attempt is not successful in a shock patient, immediately choose an alternate percutaneous site and also begin an immediate venous cutdown or perform IO catheterization. The cephalic veins and external jugular veins are ideal for peripheral catheterization.

   - The proximal cranial medial tibia and the proximal lateral humerus are ideal for IO catheter placement, using the same technique as for people (See Figures 34-37). Most MWDs weigh >40#, so use adult (25mm X 15 gauge) IO catheters. Use pediatric (15mm X 15 gauge) IO catheters in dogs weighing less than 40#.

2. Give crystalloid fluids as the first-line treatment.[9-14]

   - Normosol-R® or Plasmalyte-A® are optimal for dogs; however, saline or LRS are acceptable in emergent cases.

   - Crystalloid fluid challenges, as needed based on response to therapy, are better than large volume fluid administration.[11-13] Be prepared to administer up to 90 mL/kg of crystalloids in the first hour (1 blood volume for the dog). Aggressive, but careful, fluid delivery, with frequent reassessment of the patient's status, is critical. Most MWDs can be resuscitated with much less than this calculated maximum volume.

   - For quick reference, ADD a ZERO to the dog's body weight (***in pounds***) to approximate a safe but effective bolus volume. For example, a 45# dog would need about a 450 mL bolus, and a 75# dog would need about 750 mL as a bolus.

3. Use synthetic colloids and hypertonic saline (HTS) in dogs with refractory shock. Very limited data in dogs suggest increased risks,[15-18] but dogs do not seem as sensitive to the adverse effects of these fluids as are people. Two recent studies in dogs showed no adverse side effects, specifically acute kidney injury, with tetrastarch use.[19,20] The benefits outweigh the risks, so be aggressive with synthetic colloid and HTS.[15-17]

   - Give hydroxyethyl starch (HES) as an IV or IO bolus of 10-20 mL/kg total over 5-10 minutes if clinical signs of shock do not abate after the first 30 minutes or the first 2 bolus crystalloid challenges), or response to crystalloid challenges is not sustained.[11-13,15,20,21] Repeat this bolus if no response to therapy.

   - Use HTS IV boluses, if 7.0 - 7.5% HTS is available, for MWDs that fail to respond to 2 or 3 boluses of crystalloids and/or 1 or 2 boluses of HES. Give 4 mL/kg over 5 minutes.[11-13,20] Do not administer HTS by the IO route.

Standard Shock Therapy (continued)

4. Human serum albumin (HSA) use. Do not give HSA or other synthetic colloids (e.g., dextrans) to MWDs, because severe allergic reactions are possible (HSA) and coagulopathies are common (dextrans). Some data suggest benefit in a very limited subset of patients with severe hypoalbuminemia,[22,23] but risks far outweigh potential benefit in dogs with shock.

5. Blood product use. Canine blood products are not available for immediate HCP use.[2] Dogs cannot be transfused with human blood products. HCPs will have to manage hemorrhagic shock with crystalloid and colloid therapy.

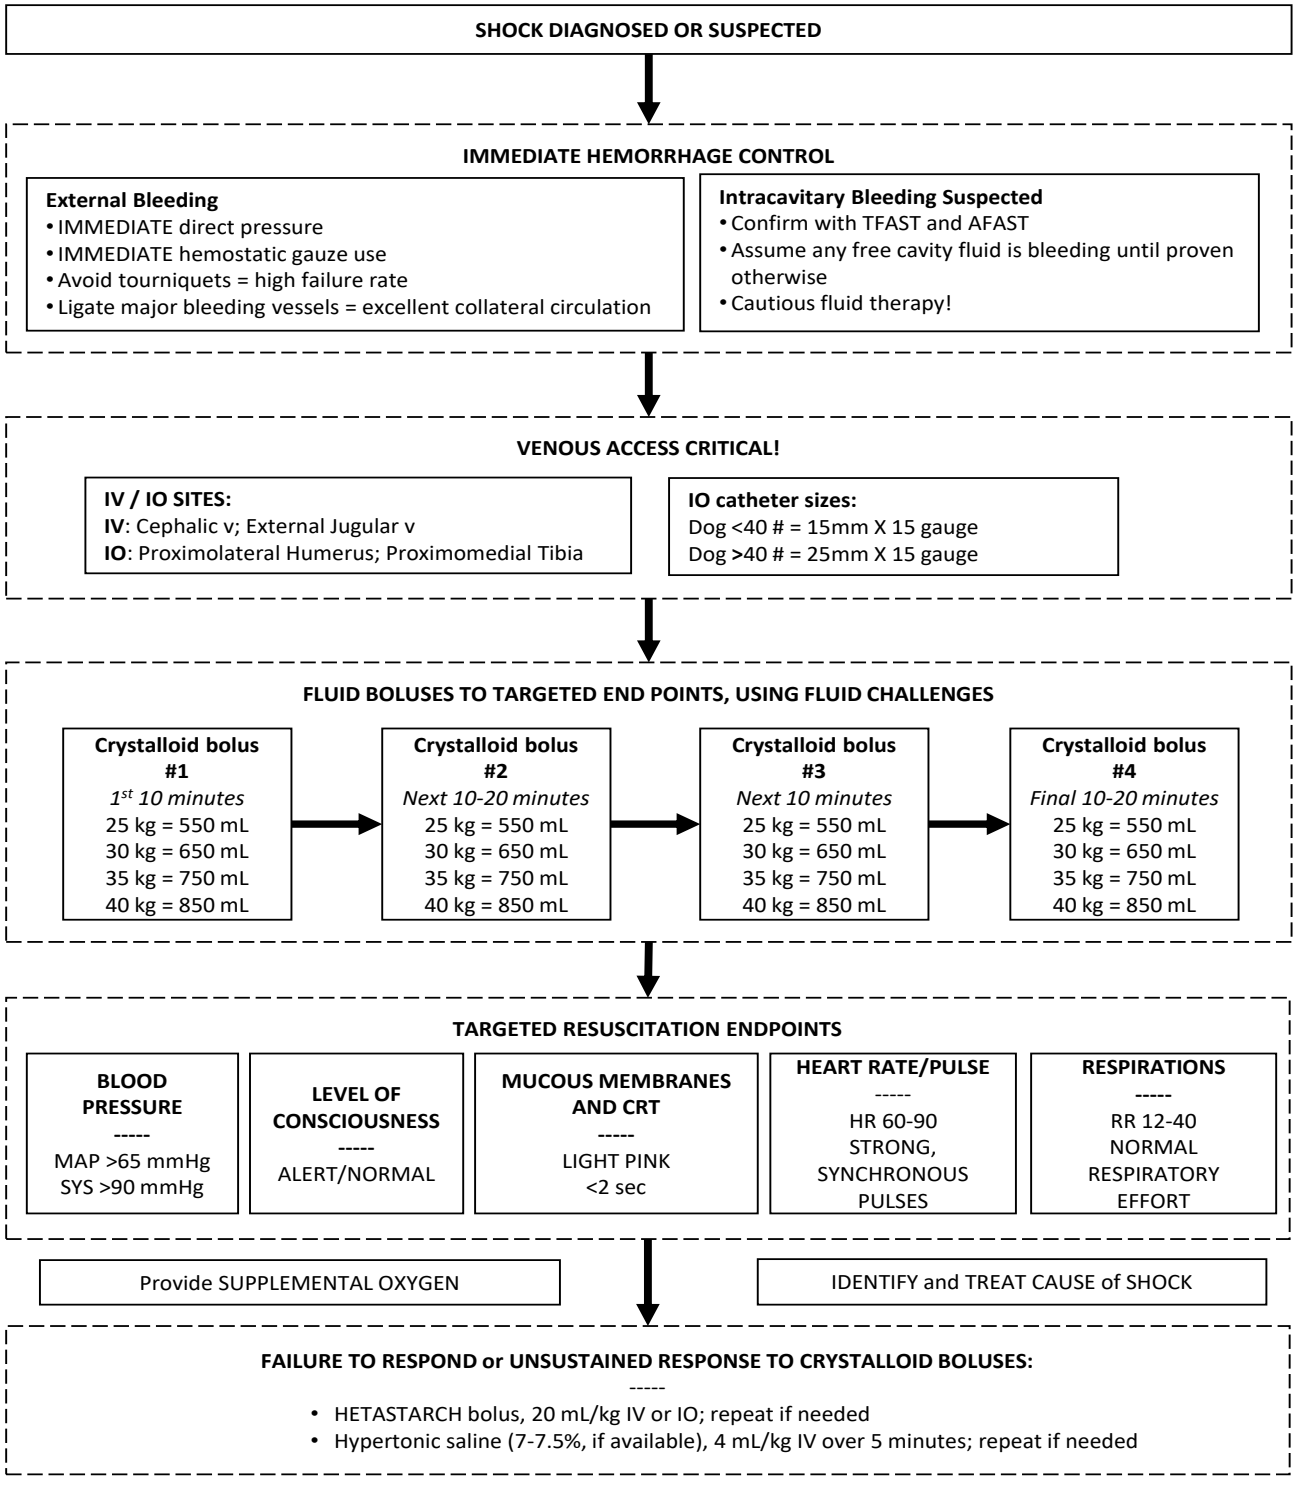
6. Tranexamic acid (TXA) and ε-aminocaproic acid (EACA) use. There is limited, but promising, data to guide use of TXA[24-27] and EACA[28] in dogs with hemorrhage. Dogs appear to be hyperfibrinolytic compared to humans, suggesting higher doses of TXA may be needed in dogs. Consider TXA or EACA if the dog is anticipated to need significant blood transfusion, such as severe hemorrhagic shock, limb amputation, penetrating torso trauma with severe non-compressible bleeding, because canine blood products are not available. Administer these drugs as soon as possible after trauma, but NO LATER THAN 3 HOURS post injury.
   - TXA: 10 mg/kg in 100 mL NS or LRS, IV over 15 min.
   - EACA: 150 mg/kg in 100 mL NS or LRS, IV over 15 min.
   - If bleeding continues, a CRI of additional TXA at 10 mg/kg/hour for 3 hours can be administered.

7. Targeted shock resuscitation end points that are practical for HCPs include systolic and mean arterial pressures, level of consciousness and mentation, mucous membrane color and capillary refill time, HR, RR, and pulse quality.
   - Target a MAP >65 mmHg or a Sys >90 mmHg. Note that neonatal or pediatric blood pressure cuffs must be used (See Chapter 2).
   - Target normal level of consciousness (LOC) and an alert mentation.
   - Target light pink-to-salmon pink MM and a CRT <2 seconds.
   - Target a HR that is 60-90 beats per minute at rest with a strong, synchronous pulse quality.
   - Target a respiratory rate at rest of 12-40 breaths per minute with normal effort.
   - Once shock has abated, continue IV crystalloid fluids at 3-5 mL/kg/hour for 12-24 hours to maintain adequate intravascular volume.

8. Provide supplemental oxygen therapy. Oxygen supplementation is critical. Every shock patient should receive supplemental oxygen therapy until stable (See Chapter 3).

9. Identify and treat the cause of shock. The cause of shock must be corrected, if possible.
   - Patients with massive intra-abdominal or intrathoracic bleeding need surgery to find the site of bleeding and surgically correct the loss of blood, with the caveats in mind as discussed previously.
   - Chapter 4 addresses emergent resuscitative thoracotomy. Chapter 7 addresses emergent abdominal laparotomy.
   - Euthanasia should be considered to prevent undue suffering for a MWD for which emergent surgery is deemed necessary but cannot be performed or has proven unsuccessful (See Chapter 21).

Figure 33. Clinical Management Algorithm for Shock Resuscitation in MWDs.



SHOCK DIAGNOSED OR SUSPECTED
IMMEDIATE HEMORRHAGE CONTROL
External Bleeding
• IMMEDIATE direct pressure
• IMMEDIATE hemostatic gauze use
• Avoid tourniquets = high failure rate
• Ligate major bleeding vessels = excellent collateral circulation
Intracavitary Bleeding Suspected
• Confirm with TFAST and AFAST
• Assume any free cavity fluid is bleeding until proven otherwise
• Cautious fluid therapy!
VENOUS ACCESS CRITICAL!
IV / IO SITES:
IV: Cephalic v; External Jugular v
IO: Proximolateral Humerus; Proximomedial Tibia
IO catheter sizes:
Dog <40 # = 15mm X 15 gauge
Dog >40 # = 25mm X 15 gauge
FLUID BOLUSES TO TARGETED END POINTS, USING FLUID CHALLENGES
Crystalloid bolus #1
1st 10 minutes
25 kg = 550 mL
30 kg = 650 mL
35 kg = 750 mL
40 kg = 850 mL
Crystalloid bolus #2
Next 10-20 minutes
25 kg = 550 mL
30 kg = 650 mL
35 kg = 750 mL
40 kg = 850 mL
Crystalloid bolus #3
Next 10 minutes
25 kg = 550 mL
30 kg = 650 mL
35 kg = 750 mL
40 kg = 850 mL
Crystalloid bolus #4
Final 10-20 minutes
25 kg = 550 mL
30 kg = 650 mL
35 kg = 750 mL
40 kg = 850 mL
TARGETED RESUSCITATION ENDPOINTS
BLOOD PRESSURE
MAP >65 mmHg
SYS >90 mmHg
LEVEL OF CONSCIOUSNESS
ALERT/NORMAL
MUCOUS MEMBRANES AND CRT
LIGHT PINK
<2 sec
HEART RATE/PULSE
HR 60-90
STRONG, SYNCHRONOUS PULSES
RESPIRATIONS
RR 12-40
NORMAL RESPIRATORY EFFORT
Provide SUPPLEMENTAL OXYGEN
IDENTIFY and TREAT CAUSE of SHOCK
FAILURE TO RESPOND or UNSUSTAINED RESPONSE TO CRYSTALLOID BOLUSES:
• HETASTARCH bolus, 20 mL/kg IV or IO; repeat if needed
• Hypertonic saline (7-7.5%, if available), 4 mL/kg IV over 5 minutes; repeat if needed

Figures 34-37. Intra-osseous Catheter Placement (Tibia) in a MWD.
Note: Sterile draping is removed to provide better visualization; perform catheterization using sterile technique.

Figure 34 shows the general landmark for IO catheterization on the upper medial aspect of the hind leg of the dog.

Figure 35 shows the intended insertion site (red oval) on the proximal medial tibial crest, just distal to the knee joint. The area should be clipped of hair and prepared for aseptic catheter placement.

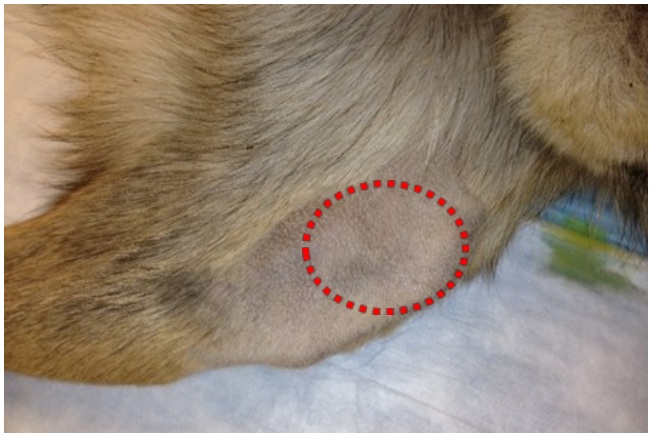


Figure 36 shows insertion of a pediatric IO catheter in the proximomedial tibia using the EZ-IO® device.

Figure 37 shows full insertion of the IO catheter, after removal of the stylet.

Abdominal Trauma

Abdominal Injuries in Deployed MWDs

These injuries are the result of either blunt abdominal trauma (BAT) or penetrating abdominal trauma (PAT).[1-7] Management of these types of injuries differs markedly. Conservative medical management is usually indicated for MWDs with blunt abdominal trauma; whereas, urgent exploratory surgery is generally recommended for MWDs with penetrating injuries. A clinical management algorithm for MWDs with abdominal trauma is provided. (See Figure 38).

Physical Exam Finding Supporting Abdominal Trauma

Suspect significant intra-abdominal injury in any MWD that presents with abdominal rigidity or sensitivity to palpation, increasing abdominal size over time, visible bruising of the abdominal wall, or failure to respond to or deterioration in face of aggressive trauma resuscitation. Wounds involving more than the skin and superficial subcutaneous tissues dictate detailed examination to determine if the body wall was penetrated, and may require surgical exploration.

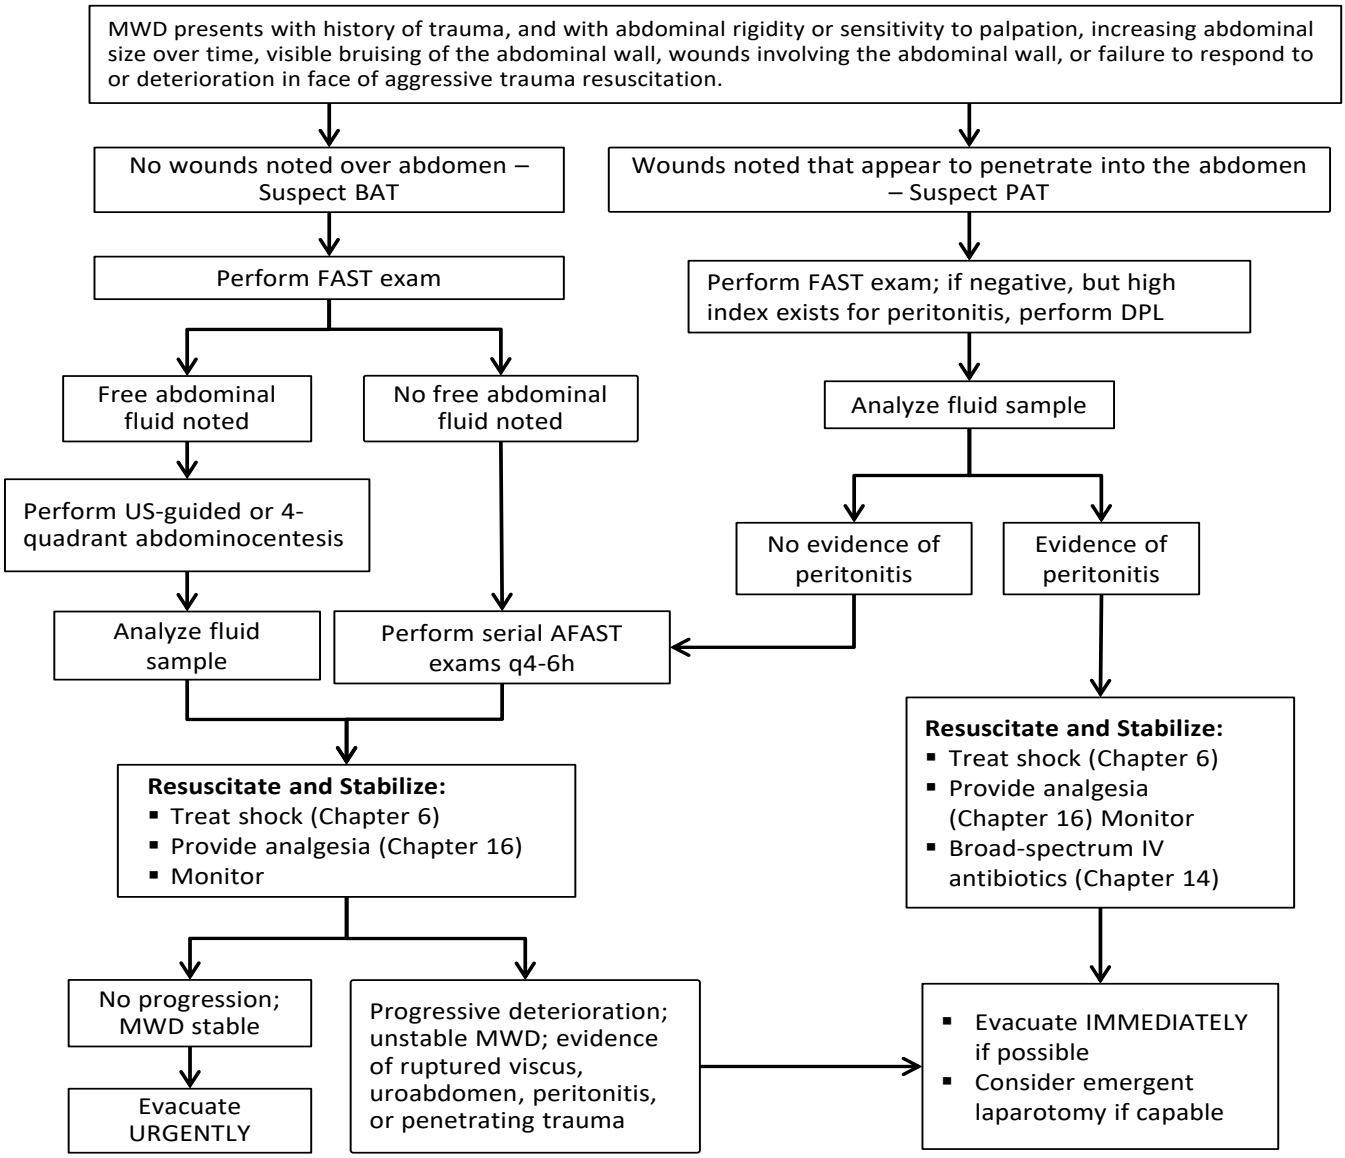
Diagnosis of Abdominal Trauma

The diagnostic method of choice for evaluating patients with suspected blunt abdominal trauma is the abdominal FAST (AFAST) exam, with ultrasound-guided or 4-quadrant needle abdominocentesis if free abdominal fluid is noted. Consider CT if advanced imaging is available.

Perform an AFAST exam during the initial evaluation phase of every MWD with a history of trauma, acute collapse, or weakness. FAST is proven in dogs to be extremely reliable in detecting free abdominal fluid and can be performed rapidly during resuscitation.[8]

- Examine 4 quadrants. Probe placement for dogs includes the diaphragmatic-hepatic site (DH) caudal to the liver, the splenorenal site (SR) around the left kidney, the cystocolic site (CC) cranial to the urinary bladder, and the hepatorenal site (HR) around the right kidney.[8] Figure 39 on page 51 provides a schematic showing probe placement in dogs. Fan the probe in the cranial-caudal and lateral-medial planes.

Figure 38. Clinical Management Algorithm for MWDs with Abdominal Trauma.



MWD presents with history of trauma, and with abdominal rigidity or sensitivity to palpation, increasing abdominal size over time, visible bruising of the abdominal wall, wounds involving the abdominal wall, or failure to respond to or deterioration in face of aggressive trauma resuscitation.
No wounds noted over abdomen – Suspect BAT
Wounds noted that appear to penetrate into the abdomen – Suspect PAT
Perform FAST exam
Perform FAST exam; if negative, but high index exists for peritonitis, perform DPL
Free abdominal fluid noted
No free abdominal fluid noted
Analyze fluid sample
Perform US-guided or 4-quadrant abdominocentesis
No evidence of peritonitis
Evidence of peritonitis
Analyze fluid sample
Perform serial AFAST exams q4-6h
Resuscitate and Stabilize:
Treat shock (Chapter 6)
Provide analgesia (Chapter 16) Monitor
Broad-spectrum IV antibiotics (Chapter 14)
Resuscitate and Stabilize:
Treat shock (Chapter 6)
Provide analgesia (Chapter 16)
Monitor
No progression; MWD stable
Progressive deterioration; unstable MWD; evidence of ruptured viscus, uroabdomen, peritonitis, or penetrating trauma
Evacuate IMMEDIATELY if possible
Consider emergent laparotomy if capable
Evacuate URGENTLY

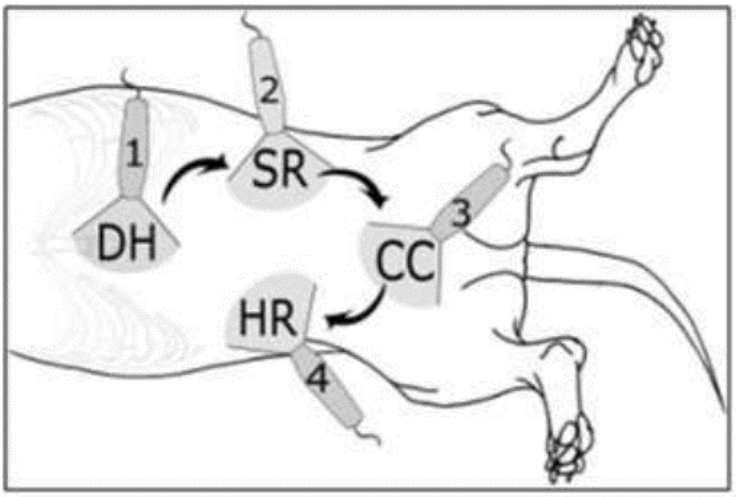


Figure 39. Imaging Locations for AFAST.

Figure 39 shows ultrasound probe placement sites for AFAST scanning of dogs. The dog's head is to the left; the dog is in right lateral recumbency.

DH = diaphragmatic-hepatic

SR = splenorenal

CC = cystocolic

HR = hepatorenal

- Score the AFAST exam, with 1 point for each quadrant that has free fluid identified. Perform serial FAST exams every 4-6 hours and compare scores. MWDs with increasing scores should be monitored closely and prepared for URGENT evacuation or surgery, as exploratory surgery may be necessary for MWDs with scores of 3/4 or 4/4[8] or with clinical deterioration.

Perform a 4-quadrant abdominocentesis in any patient with free fluid in the abdomen.[9] This technique is quick and easy to perform, and usually differentiates abdominal hemorrhage or biliary or urinary tract injury. The general rule of thumb is that a positive peritoneal tap is a reliable indicator that some hemorrhage has occurred or that free urine or bile is in the abdominal cavity, but that a negative tap does not rule these out.

- Place the dog in lateral recumbency. Clip the abdomen of hair and prepare for aseptic procedure.
- "Divide" the abdomen into 4 quadrants, and tap each quadrant sequentially, unless a positive yield is obtained in a quadrant. Perform abdominocentesis on the "down" quadrants, rolling the dog over for the opposite quadrants.
- A large bore needle (18 or 20 gauge) is quickly inserted perpendicular to and through the body wall approximately 2 inches off the midline in each quadrant. Alternatively, a large bore over-the-needle catheter can be aseptically fenestrated and inserted into the abdomen. This increases the likelihood for higher yield because the fenestrations are less likely to occlude.
- The presence of blood suggests intra-abdominal hemorrhage, and the presence of clear or yellowish fluid suggests urine.
- As much sample is collected by gravity drip or slight suction with a 3 cc syringe and saved in serum tubes and EDTA tube. The fluid is analyzed cytologically, and for glucose, lactate, hematocrit, total protein concentration, BUN or creatinine, bilirubin, amylase or lipase, ALT, and ALKP.
  - Assess cytology for the presence of bacteria or other organisms, or fecal or food material that would suggest gastrointestinal rupture and contamination.
  - The peritoneal fluid glucose and lactate concentrations can be measured and compared to serum levels to aid in differentiating possible septic peritonitis in the absence of cytological evidence. An increased abdominal fluid lactate >2.5 mmol/L or an abdominal fluid-to-peripheral blood lactate

difference of >2 mmol/L strongly suggests a septic peritonitis.[10,11] An abdominal fluid glucose concentration that is >20 mg/dL lower than peripheral blood glucose concentration strongly suggests a septic peritonitis.[10,11]

- The hematocrit and total protein concentration are compared to a simultaneously collected peripheral blood sample. If the hematocrit and total protein concentration are similar, significant hemorrhage into the abdomen is probable, and surgical intervention may be necessary, but base this decision on the patient's status more than the actual number. If the hematocrit and total protein concentration of the abdominal fluid are very low, minor hemorrhage is more likely, and a more conservative approach – based on the patient's status – is recommended.

- The presence of bilirubin suggests gall bladder injury, although this may not be present for several days after trauma.[9] Amylase or lipase with values higher than systemic circulation suggests pancreatic trauma. A ratio of 1.4:1 in comparing abdominal fluid potassium with peripheral blood potassium concentrations has 100% sensitivity and specificity for uroperitoneum.[12] Comparison of abdominal fluid creatinine to peripheral blood creatinine concentrations shows 86% sensitivity and 100% specificity for ratios >2:1.[12] Elevated ALT suggests direct liver injury, and elevated ALKP suggests bowel injury or ischemia, but these are non-specific and can rarely be used to guide management decisions.

Consider diagnostic peritoneal lavage (DPL) in any MWD in which major abdominal trauma is suspected, but AFAST and abdominocentesis are unrewarding.[9] If available, CT or MRI may be better modalities.

- Use a specialized DPL catheter or aseptically fenestrate a large bore over-the-needle (OTN) catheter.
- Sedate the patient if necessary and locally anesthetize the site of catheter insertion using 20 mg lidocaine.
- Percutaneously insert the catheter; a small stab incision may be needed if a larger catheter is used.
- Immediately after entering the abdominal cavity, remove the needle and advance the catheter in a caudodorsal direction to avoid the omentum and cranial abdominal organs.
- Infuse 20 mL/kg warmed, sterile saline aseptically over 5-10 minutes.
- Aseptically plug the catheter and gently roll the MWD from side to side for several minutes to allow the infusate to mix.
- Either aspirate effluent or allow gravity-dependent drainage to collect a sample for analysis.
- Analyze the sample for the same parameters described for abdominocentesis.

Blunt Abdominal Trauma (BAT)

The usual organs in MWDs subjected to blunt trauma are the spleen, liver, and urinary bladder, in this order of frequency. Splenic and hepatic injuries are usually fractures of the organ; major vessel trauma is uncommon.[1-7]

- Intra-abdominal hemorrhage. Most hemoperitoneum cases in MWDs are due to splenic and hepatic frac-

tures, which can vary markedly in size, with a significant difference in quantity of blood lost into the abdomen.

- The majority of MWDs with BAT and intra-abdominal hemorrhage that survive to admission can be successfully managed conservatively, since most of the time the source of hemorrhage is small liver and splenic fractures. These usually will spontaneously cease bleeding given time and conservative fluid therapy. Monitor the MWD closely, as some will require exploratory laparotomy and surgical correction of hemorrhage, especially those that do not respond or deteriorate.
- Given the difficulty in maintaining an abdominal counterpressure bandage, and the risk of respiratory compromise, do not apply an abdominal counterpressure bandage on a MWD.
- Patients with massive intra-abdominal bleeding need surgery to find the site of bleeding and surgically correct the loss of blood. There may be instances in which emergent laparatomy is necessary by HCPs to afford a chance at patient survival. See **Emergent Abdominal Laparotomy** in this chapter for guidance.

- Urinary tract trauma. Urinary bladder rupture, with uroperitoneum, is fairly common, especially if the animal had not voided before the trauma.
  - MWDs with acute urologic trauma and uroperitoneum should be stabilized for other injuries, and aggressively managed for shock. Primary repair of a ruptured urinary bladder or other urologic injury must wait until the patient stabilizes to minimize the risk of complications associated with taking an unstable patient to surgery.
  - In many cases, urologic injury is not apparent for several days after trauma, so a high index of suspicion must be maintained. Special studies (ultrasound, excretory urography, contrast urethrocystography) may need to be performed to rule out urologic trauma.
  - In patients with known urologic tears and urine leakage, abdominal drains may be indicated if surgery is delayed for several days while the patient stabilizes. This will allow removal of urine, which will minimize chemical peritonitis and electrolyte and acid-base imbalances (metabolic acidosis, hyperkalemia). Intensive fluid therapy to correct or prevent electrolyte and acid-base imbalances is often necessary, especially if several days have passed since traumatic injury.
  - Surgical repair must only be performed after the patient is stabilized. Patients with severe uroabdomen need surgery to define the extent of injury and correct the problem. There may be instances in which emergent laparatomy is necessary by HCPs to afford a chance at patient survival. See **Emergent Abdominal Laparotomy** in this chapter.
- Ruptured abdominal viscus. Patients with a ruptured gastrointestinal viscus are candidates for emergent exploratory surgery to identify the part of the tract that is injured and allow primary repair. Delay in repairing bowel perforation can rapidly lead to septic peritonitis, septic shock, and rapid patient deterioration.[13]

TABLE 11. ANTIBIOTIC SELECTION AND DOSING FOR MWDS			
ANTIBIOTIC	**DOSE FOR MWD**	**ROUTE**	**FREQUENCY**
Amoxicillin-Clavulanic Acid	13.75 mg/kg	PO	q 12 h
Ampicillin Sulbactam	20 – 30 mg/kg	IV q	8 h
Cefazolin	20 -30 mg/kg	IV q	8 h
Cefotaxime	22 mg/kg	IV q	8 h
Ceftriaxone	25 mg/kg	IV q	8-12 h
Cephalexin	20 – 30 mg/kg	PO q	12 h

- Broad-spectrum antibiotic therapy is vital, especially against anaerobic and gram negative bacteria. Table 11 lists antibiotic options for initial use in MWDs with ruptured viscus or septic peritonitis.
- Shock management is of special importance. Every attempt must be made to stabilize the patient as much as possible, with URGENT evacuation to a veterinary facility for definitive repair.
- Patients with ruptured abdominal viscus need surgery to define the extent of injury and correct the problem. There may be instances in which emergent laparatomy is necessary by HCPs to afford a chance at patient survival. See **Emergent Abdominal Laparotomy** in this chapter for guidance.

Penetrating Abdominal Trauma

Exploratory laparotomy as a diagnostic and therapeutic modality is clearly indicated in trauma patients if penetrating trauma is highly suspected or known, or if the patient's status deteriorates despite aggressive resuscitation attempts and major organ hemorrhage or injury is suspected or known.[13]

- Non-invasive diagnostic imaging is recommended in an attempt to confirm a suspicion of major internal organ injury. Perform AFAST, abdominocentesis, and/or DPL as necessary, and advanced imaging if available.
- Patients with penetrating abdominal injuries and a high index of suspicion for peritonitis, bowel injury, ruptured viscus, major hemorrhage, or other life-threatening problem need emergent surgery to further define the extent of injury and provide corrective surgery. There may be instances in which emergent laparatomy is necessary by HCPs to afford a chance at patient survival. See **Emergent Abdominal Laparotomy** in this chapter for guidance. Empiric antibiotic therapy is critical (See Table 11).

Emergent Abdominal Laparotomy

Some patients with severe abdominal trauma require surgery to define the extent of injury and attempt repair of the problem, remembering the caveats discussed previously.[13]

- Surgical management includes an approach through the ventral midline under general anesthesia with the dog in dorsal recumbency, to expose the abdominal cavity.

- A complete abdominal exploratory is necessary to define all injuries. Routine exploratory techniques used for people are appropriate for dogs.
- Surgical management will depend on the injuries noted. Expect hemoabdomen, liver and spleen trauma with hemorrhage, major vessel injuries with hemorrhage, bowel perforation, hollow viscus injuries, urinary tract injuries, and abdominal wall injuries. Repair of injuries in the dog is essentially the same as repair in human casualties.
- Abdominal wall closure is in 3 layers: 0 non-absorbable simple interrupted linea alba closure; 2-0 absorbable simple continuous subcutaneous closure; routine skin closure.

CHAPTER 8

Gastrointestinal Emergencies

Among other gastrointestinal emergencies, MWDs are at increased risk for development of two life-threatening gastrointestinal emergencies: Gastric Dilatation-Volvulus Syndrome, and mesenteric volvulus.[1-3]

Gastric Dilation-Volvulus Syndrome (GDV or "bloat")

GDV is a multifactorial, rapidly progressing, life-threatening surgical emergency common in large-breed dogs, to include MWDs.[4] In GDV, the stomach rapidly dilates (gastric dilation) with fluid, food, and air, and then rotates along the long axis (volvulus). When volvulus develops, the esophagus and duodenum become twisted, preventing passage of stomach contents. The amount of air, food, and fluid that accumulates is dramatic and progressively worsens – typically over 30 minutes to 4 hours – and causes shock by interfering with venous return from the abdomen and pelvic limbs. Death in cases of GDV in the short-term is due to shock. Death in the long-term is due to gastric wall necrosis and rupture with secondary sepsis, DIC, or cardiac arrhythmias.[4-5]

Most MWDs have had a prophylactic gastropexy performed before deployment. This elective surgical procedure creates a surgical adhesion between the stomach and the inner abdominal wall that is very effective at preventing volvulus. While gastric dilation (GD) can still occur, this in and of itself is seldom severe enough to cause shock, since accumulated gas and stomach contents can be vomited or passed into the bowel. However, HCPs should recognize that many deployed working dogs operated by Allied military forces and DoD contractors likely have not been gastropexied, and – in rare cases – a gastropexy can fail, and GDV must be a differential in dogs with typical signs.

Clinical Signs of GDV

GDV patients classically present with a constellation of clinical signs that should prompt immediate evaluation. MWD handlers are trained to recognize these signs, and handlers may have performed emergency care before the dog is presented to a MTF, to include gastric decompression.

Early signs of GDV include varying degrees of abdominal distention (tympany) from stomach filling with air, food, and fluid; nonproductive retching, attempted vomiting without result, or retching a small amount of saliva ("dry heaves"); signs of pain (grunting, especially when the stomach or abdomen is palpated); signs of anxiety, which is commonly noted as pacing, anxious stares, and inability to get comfortable when lying down; and signs of compensatory shock (tachycardia, tachypnea).

As GDV progresses, clinical signs of advancing shock ensue. MWDs may present at any time in the continuum of the syndrome, and often present *in extremis* if recognition or care has been delayed.

HCPs should assume GDV is present and take immediate action if an MWD presents with signs of shock, abdominal distension, non-productive vomiting or retching, and signs of anxiety or pain.

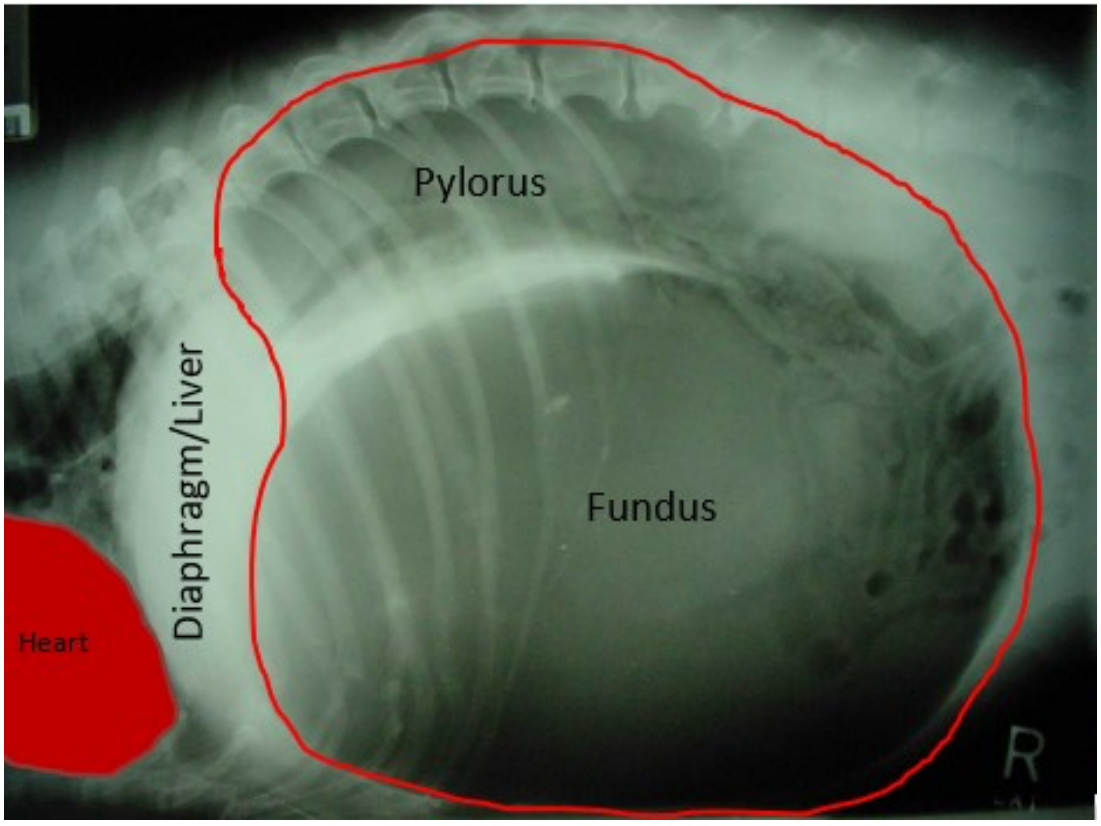
Definitive Diagnosis of GDV

Confirmation of GDV is based on abdominal radiographs that demonstrate marked gastric dilation with air (See Figure 40). Radiography, if available, is recommended if there is doubt about the diagnosis, as other conditions (e.g., hemoperitoneum, abdominal neoplasia, ascites) mimic some of the signs of GDV. Generally, a single right lateral radiograph is sufficient.

Management of GDV

A management algorithm is provided (See Figure 41). The hallmark immediate treatment of GDV includes rapid decompression of gas from the dilated stomach, shock therapy, monitoring for complications, repeated decompression if dilation recurs, and rapid evacuation to veterinary facilities for definitive surgery. GDV is a surgical emergency; surgery is required to derotate the stomach and perform gastropexy, and to perform partial gastric resection or splenectomy if warranted, with extended monitoring for common life-threatening sequellae in the post-operative period.

Figure 40. Radiograph with Gastric Dilation Volvulus.
Figure 40 shows a right lateral radiograph of a dog with marked gastric dilation due to GDV. Head is to left. Red line depicts general outline of the massively distended stomach, with the pylorus malpositioned dorsal to the fundus.



GDV Management Summary

- **Treat shock.** Provide 100% oxygen (See Chapter 4). Administer intravenous fluids to targeted end-points (See Chapter 6, Figure 33).
- **Decompress the stomach by percutaneous trocarization of the stomach:**
- Position yourself on the left side of the patient, or lay the dog with its left side down (left lateral recumbency).
- **Locate the insertion point:**
  - Palpate the last rib.
  - Move the hand 2 inches caudal to the last rib, midway between the spine and the ventral border of the abdomen on the right side.
  - Auscult the lateral abdominal wall at the most distended area while percussing (flicking) the abdominal wall firmly with a finger. This percussion will elicit a "pinging" sound, and the site of insertion of the trocar should be at the point of loudest "pinging."
- Clip the hair over a 6-inch X 6-inch area over this area. Prepare the area using surgical scrub.
- Forcefully insert a 10-14 gauge trocar or 14-18 gauge IV over-the-needle catheter through the skin, abdominal wall, and stomach wall. Note gas or air escaping through the trocar/needle from the stomach to signify a successful trocarization.
- Note: If no air or gas is coming from the trocar, attempt gastric trocarization one more time. If still unsuccessful, do not attempt any further trocarizations. Emergent surgery is indicated if trocarisation is not possible.
- Gently apply external pressure to the abdominal wall to assist in decompressing air from the stomach.
- Once the majority of the air is evacuated, remove the trocar/needle, because leaving it inserted may cause trauma to internal organs.

Common Complications Associated with GDV

Monitor for the most common complications seen in MWDs with GDV, to include ventricular arrhythmias, persistent shock, recurrent gastric dilation, nausea and vomiting, ileus, electrolyte abnormalities (especially potassium), and metabolic acidosis. Multi-organ failure may develop, depending on the degree and duration of shock.

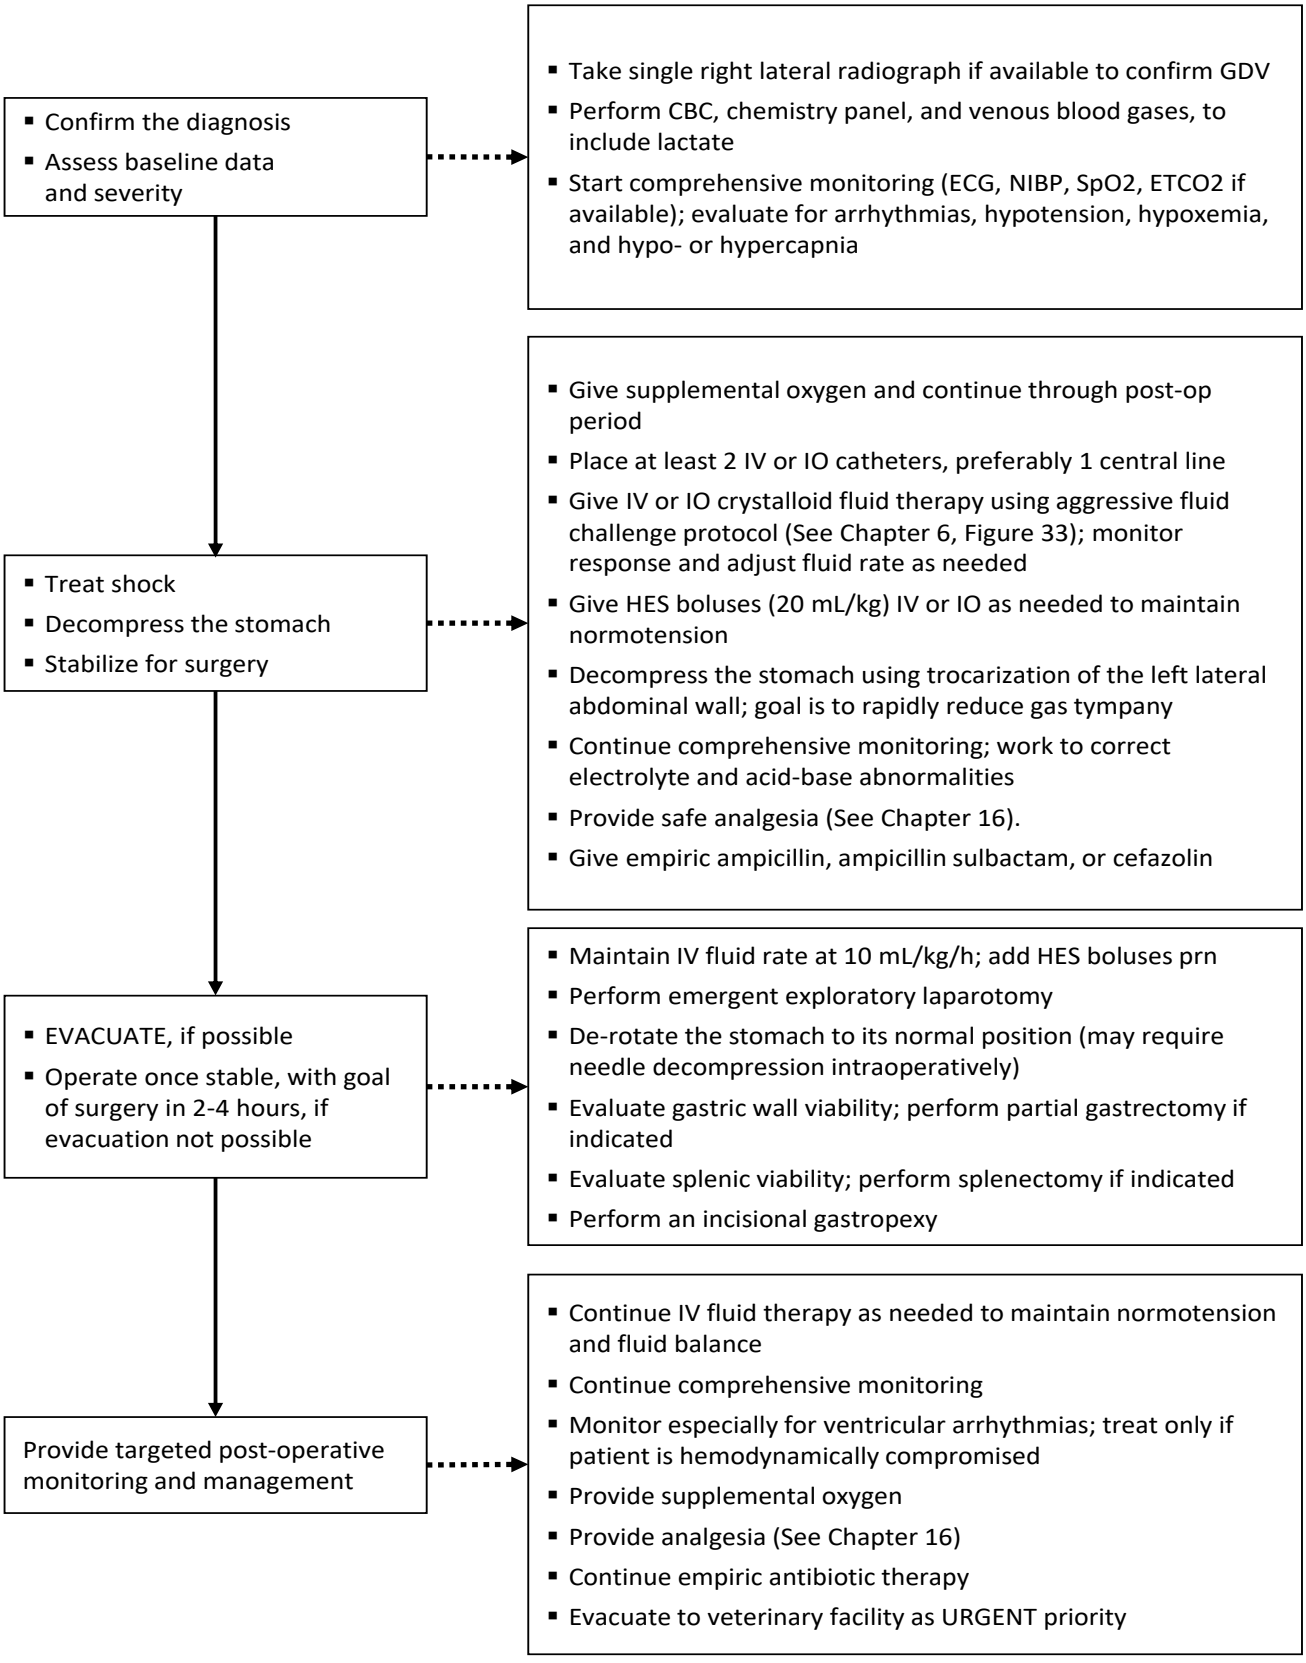
Definitive Surgical Management of GDV

Evacuate the MWD to a veterinary facility as soon as it is stabilized. Any MWD with GDV should be considered an URGENT casualty. Definitive surgical management – consisting of exploratory laparotomy, derotation of the stomach, gastropexy, and possible partial gastric resection and/or splenectomy – requires trained personnel intimate with the anatomy and physiology of the dog.

Emergency surgical exploration of the abdomen and attempted surgical management of GDV by HCPs in the deployed setting may be necessary if evacuation will be delayed more than 4-6 hours.

- It is essential to counter shock and stabilize the dog before considering operative management.
- Surgical management includes an approach through the ventral midline under general anesthesia, with the dog in dorsal recumbency, to expose the abdominal cavity (See Chapter 16.)
- GDV is confirmed once the abdomen is open by identifying a dilated stomach covered by omentum.
- The stomach is de-rotated to its normal position by grasping the stomach on both extreme lateral aspects simultaneously, and rotating the stomach counterclockwise (when viewed from the dog's right side in dorsal recumbency).
- A markedly tympanic stomach may need to be further decompressed by intraoperative needle decompression with suction to allow adequate manipulation.
- Typically, the gastric wall has variable degrees of bruising, especially at the cardia, and may have developed partial- or full-thickness necrosis. If bruising persists or worsens intraoperatively, or if gastric wall necrosis is suspected, perform a partial gastrectomy of suspect gastric wall. Gastrectomy is ideally performed using TA or GIA surgical stapling equipment or an inverting double-layer gastric wall suture pattern of non-absorbable suture. Note that postoperative mortality in dogs that require gastrectomy is approximately 25 -35%, compared to mortality <10% in dogs that do not require gastrectomy.
- Typically, intra-abdominal bleeding is encountered due to rupture of the short gastric arteries and/or splenic injury. Assess the viability of the spleen and perform splenectomy if splenic thrombosis, marked splenic vessel injury and bleeding, or splenic lacerations are noted. Arcade ligation, with special attention to the major splenic vessels, is optimal, and is best done with LDS stapling equipment (for vessels <4 mm diameter) and suture ligation (for vessels >4 mm diameter) using transfixation sutures.
- Perform an incisional gastropexy (to prevent future GDV). Create a 3-4 cm incision in the seromuscular layer of the right pyloric area of the stomach wall. Create a similarly-sized incision in the right ventrolateral abdominal wall musculature. Appose the margins of the gastric wall incision against the margins of the incision in the abdominal wall musculature and create a gastropexy by suturing each margin using 0 or 2-0 non-absorbable suture.
- Abdominal wall closure is in 3 layers: 0 non-absorbable simple interrupted linea alba closure; 2-0 absorbable simple continuous subcutaneous closure; routine skin closure.

Figure 41. Clinical Management Algorithm for Gastric Dilatation-Volvulus (GDV) in Military Working Dogs.



Confirm the diagnosis
Assess baseline data and severity
Take single right lateral radiograph if available to confirm GDV
Perform CBC, chemistry panel, and venous blood gases, to include lactate
Start comprehensive monitoring (ECG, NIBP, SpO2, ETCO2 if available); evaluate for arrhythmias, hypotension, hypoxemia, and hypo- or hypercapnia
Treat shock
Decompress the stomach
Stabilize for surgery
Give supplemental oxygen and continue through post-op period
Place at least 2 IV or IO catheters, preferably 1 central line
Give IV or IO crystalloid fluid therapy using aggressive fluid challenge protocol (See Chapter 6, Figure 33); monitor response and adjust fluid rate as needed
Give HES boluses (20 mL/kg) IV or IO as needed to maintain normotension
Decompress the stomach using trocarization of the left lateral abdominal wall; goal is to rapidly reduce gas tympany
Continue comprehensive monitoring; work to correct electrolyte and acid-base abnormalities
Provide safe analgesia (See Chapter 16).
Give empiric ampicillin, ampicillin sulbactam, or cefazolin
EVACUATE, if possible
Operate once stable, with goal of surgery in 2-4 hours, if evacuation not possible
Maintain IV fluid rate at 10 mL/kg/h; add HES boluses prn
Perform emergent exploratory laparotomy
De-rotate the stomach to its normal position (may require needle decompression intraoperatively)
Evaluate gastric wall viability; perform partial gastrectomy if indicated
Evaluate splenic viability; perform splenectomy if indicated
Perform an incisional gastropexy
Provide targeted post-operative monitoring and management
Continue IV fluid therapy as needed to maintain normotension and fluid balance
Continue comprehensive monitoring
Monitor especially for ventricular arrhythmias; treat only if patient is hemodynamically compromised
Provide supplemental oxygen
Provide analgesia (See Chapter 16)
Continue empiric antibiotic therapy
Evacuate to veterinary facility as URGENT priority

Mesenteric Volvulus

Mesenteric volvulus (MV) is a rapidly progressive and often fatal condition in which intestinal rotation develops around the root of the mesentery. Although rare, it appears to be increasing in frequency in MWDs.[3] The case fatality rate was 92% in a recent report of 54 MWDs with MV; of these 24% were found dead and 76% were identified antemortem, and only 14% of the 126 reported cases have survived.[3] Rapid recognition is necessary to afford MWDs a chance at survival.

- In MV, the cranial mesenteric blood vessels and branches obstruct due to rotation, causing ischemic necrosis of the aborad duodenum, all the jejunum, ileum and cecum, ascending and transverse colon, and orad descending colon.
- Death is due to rapidly progressive vascular obstruction, intestinal anoxia, shock, endotoxemia, and cardiovascular failure.[3]
- Statistical analysis of MV in 54 MWDs[3] suggests key risk factors include German shepherd breed, age, prophylactic gastropexy or other abdominal surgery, history of gastrointestinal disease, use of nonsteroidal anti-inflammatory drugs, and increased humidity on the day of occurrence.

Clinical Signs and Imaging Findings Suggesting MV

- Peracute-to-acute onset of vomiting, mild abdominal distension, and shock.
- Hemorrhagic diarrhea with or without tenesmus.
- Intense abdominal pain on palpation.
- Rapidly progressive deterioration in clinical presentation.
- Extreme gas distension of the majority of the small and large bowel (See Figure 42 below).

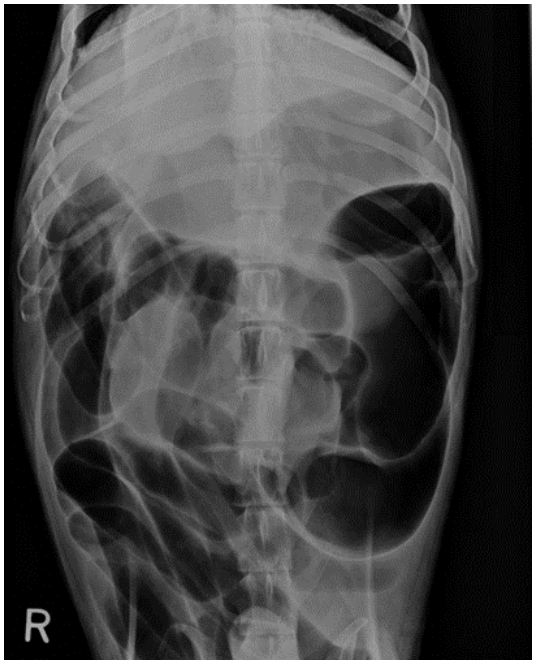


Figure 42. Lateral and ventrodorsal abdominal radiographs of a dog with MV, demonstrating near complete and severe gas distension of the entire bowel.

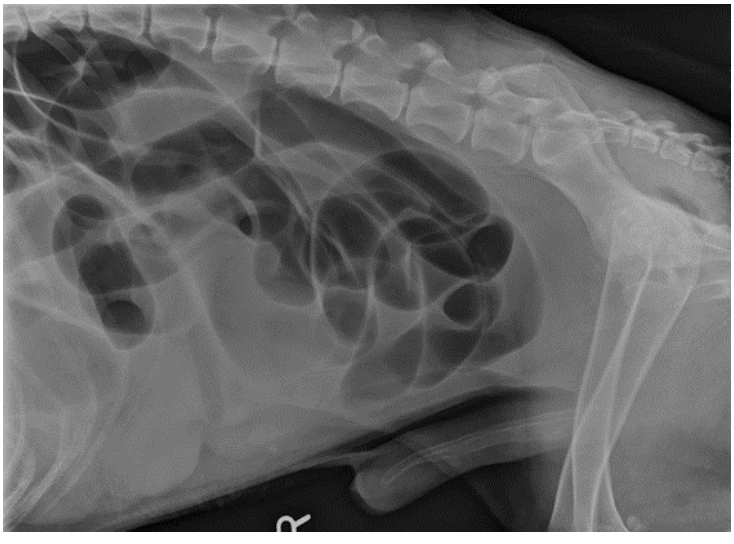

Emergent Management of MV

MV is a true surgical emergency. The hallmark immediate treatment of MV includes rapid assessment and determination of the need for emergent abdominal surgery, and aggressive shock therapy – err on the side of emergent abdominal laparotomy if clinical signs and imaging suggest MV. It is unlikely the dog can be evacuated soon enough to veterinary facilities, so be prepared to operate in the MTF. Extended monitoring for common life-threatening sequellae is required in the post-operative period.

Treat shock:

- Provide 100% oxygen (See Chapter 4).
- Administer intravenous fluids to targeted endpoints (See Chapter 6, Figure 33).

Perform emergent exploratory laparotomy:

- It is essential to begin to counter shock as you prepare for surgery.
- Surgical goals are to confirm the diagnosis, determine surgical options, and assess prognosis.
- Surgical management includes an approach through the ventral midline under general anesthesia (See Chapter 16), with the dog in dorsal recumbency, to expose the abdominal cavity.
- Operative management by resection and anastomosis should only be considered if the following conditions are met:
  - The duodenum is intact in its entirety;
  - At least 2cm of healthy ileum is present;
  - At least 50% of the jejunum is assessed to be viable;
  - No large bowel is affected.
- Abdominal wall closure is in 3 layers: 0 non-absorbable simple interrupted linea alba closure; 2-0 absorbable simple continuous subcutaneous closure; routine skin closure.

Euthanasia should be considered for an MWD presenting in extremis, or in dogs that fail to respond to therapy, that deteriorate despite care, or in which operative management is not feasible (See Chapter 21).

Common Complications Associated with MV

Monitor for the most common complications seen in MWDs with MV, to include ventricular arrhythmias, persistent shock, septic peritonitis, nausea and vomiting, ileus, and metabolic acidosis. Multi-organ failure may develop, depending on the degree and duration of shock.

CHAPTER 9

Heat Injury

Heat loss in dogs is via convection, conduction, and evaporative loss, contrasted to radiant heat loss of humans.[1] Panting is the only significant cooling mechanism for dogs. A recent study[2] in exercising MWDs demonstrates that temperatures up to 106^0 F are not uncommon in healthy MWDs during work, and that body temperature continues to increase over the course of 15 minutes after exercise; dogs not affected with heat injury rapidly normalized their temperatures within 15-20 minutes.

In MWDs, heat-induced injury usually develops due to heavy exertion in environments with high temperatures, compounded by high humidity and/or inadequate acclimation. Rarely, MWDs may develop heat-induced injury if left in or trapped in closed vehicles or containers in high-heat environment, or due to partial airway obstruction of any cause. The subsequent hyperthermia exceeds the capability of the MWD to compensate.

There are three types of heat-induced injury in veterinary patients, based on the severity of the resulting injury: mild ("heat stress"), moderate ("heat exhaustion"), or severe ("heat stroke"). Severe heat injury is associated with a mortality rate of 50-64%.[3-5]

Mild Heat Injury[6-9]

- Mild heat injury is characterized clinically by development of excessive thirst, discomfort associated with physical activity, but with controlled panting (i.e., the patient can control or reduce panting when exposed to a noxious inhalant such as alcohol).
- Treatment of mild heat injury involves removing the patient from the source of heat, stopping exercise, cooling by use of fans or movement to an air-conditioned area, and offering cold water for the dog to drink.
- Close monitoring for several hours is necessary to ensure heat stress does not progress, or rebound hypothermia does not develop.
- Key parameters to monitor, in addition to frequent body temperature measurement, include changes in mentation, development of petecchiae or ecchymoses, hematuria, weakness or collapse, clinical signs of shock (e.g., tachypnea, tachycardia, weak pulse quality, pale mucous membranes), and anxiety or restlessness.

Moderate Heat Injury[6-9]

- Moderate heat injury is present when the signs of heat stress are present, as well as weakness, anxiety, and uncontrolled panting (i.e., the patient cannot reduce or stop panting when exposed to a noxious inhalant), but CNS abnormalities are not present.
- Treatment of moderate heat injury is the same as for heat stress, but more aggressive measures at cooling are often necessary.
- The patient must be removed from the source of heat and all activity must be stopped.
- Cooling by use of fans or movement to an air-conditioned area should be done if possible. The hallmark treatment for moderate and severe heat injuries is to thoroughly soak the hair coat to the skin with tepid water to reduce core body temperature.
- Close monitoring for several hours as stated for heat stress is necessary to ensure heat exhaustion does not progress, or rebound hypothermia does not develop.

Severe Heat Injury[3-9]

- Severe heat injury is present when signs of heat exhaustion are present, coupled with varying degrees of central nervous system (CNS) abnormalities (encephalopathy). The most common CNS abnormalities include changes in mentation and level of consciousness (e.g., obtunded, stupor, coma), seizures, abnormal pupil size, cortical blindness, head tremors, and ataxia. Heat stroke is a life-threatening condition.
- It is characterized by a severe increase in core temperature and widespread, multiple organ injury with risk of progression to multi-organ failure.
- No specific body temperature defines heat stroke in MWDs; however, temperatures as low as 105.8°F have been associated with pathology. Most commonly, heat stroke is seen in MWDs with rectal temperatures >107°. Studies report multiple serious complications and high fatality rates in heat stroke patients despite proper treatment.[3-5] Table 12 describes the management of MWDs with heat-induced injury.

Initial Management Considerations for Heat-injured MWDs[7,10]

- Triage of the MWD with heat injury is similar for other types of injury or illness, but with emphasis on assessing mentation, airway and breathing, circulation, and body temperature. MWDs typically present with obtundation or stupor; however, heat stroke patients can be alert and responsive, stuporous, or comatose. MWDs presenting in stupor or coma are in imminent danger of death. Some heat stroke patients present actively seizuring.
- Anticipate that in a state of hyperthermia, the patient's initial physiological response will be to move blood to the surface vessels to maximize conductive cooling. The initial phase will generally include renal and

splanchnic vasoconstriction, peripheral vasodilatation, and increased cardiac output. Over time, if the body temperature remains high, splanchnic and renal vasoconstriction will eventually fail, creating conditions favorable for venous pooling and hypovolemia or distributive shock. Monitor continuous ECG, blood pressure, mucus membrane color, and capillary refill time.

- Rectal temperature may lag behind core body temperature by up to 15 minutes.[3] Heat stroke patients may therefore be hypothermic, hyperthermic, or normothermic upon presentation, based on cooling measures initiated by the handler and length of time since onset of heat stroke.

Emergency Management of Heat Injury[7,10,11]

- Intubate MWDs if apneic or not breathing adequately; maintain IPPV at 8-12 breaths/minute. Protect the airway if intubated while cooling with water, to reduce chances of aspiration of running water. Provide supplemental oxygen until normoxemia is confirmed with the MWD breathing room air. Use "blow by" technique if not intubated (See Chapter 3), as oxygen masks can increase humidity and prevent maximal heat dissipation.

- MWDs with a rectal temperature > 105° F require emergency cooling measures. Use a combination of cooling methods! The rate of cooling should be as rapidly as possible until the body temperature is 105° F. The most practical, most expedient, and most rapid method to reduce body temperature is to soak the patient thoroughly to the skin with room-temperature water. The patient can be placed under running tepid water in a well-drained tub or submerged partially in a tub of tepid water. The key is to soak the entire MWD as rapidly as possible, and to soak through the hair coat to soak the skin thoroughly.

- The value of intravenous fluids in patient cooling and support cannot be overstated. Unless there are specific contraindications, intravenous fluid therapy using room-temperature fluids should be initiated for any MWD with heat stroke. Adequate circulating blood and plasma volume are required for conduction to maximize heat dissipation, and IV room-temperature fluids reduces core body temperature.

- Use additional cooling methods! Direct fans on the MWD to facilitate surface cooling. If possible, move MWD to a cool room or reduce the ambient temperature of the treatment room.

- Use of cold intravenous fluids, ice-water baths, and surface cooling with ice water or ice packs are contraindicated because they cause peripheral vasoconstriction with sustained increase in core temperature, cause shivering which generates more internal heat, and promote capillary sludging which contributes to coagulopathy. Placing isopropyl alcohol on the footpads is commonly done, but is ineffective because the paw pads have such a small surface area.

- Once the patient's body temperature is <105°, the rate of cooling can be reduced to avoid rebound hypothermia. Discontinue ancillary cooling measures (e.g., remove fans, return room temperature to normal), and dry the MWD's skin.

- Once the MWD's body temperature is <103°, provide supportive warming, cease all cooling efforts, monitor temperature continuously, and be prepared to actively warm the patient to prevent an excessive drop in body temperature (rebound hypothermia). Although warming a patient with a temperature of 103° F may

seem counterintuitive, HCPs should anticipate a period of rebound hypothermia, and understand that the delay between rectal temperature and true core temperature likely means that the true core temperature may be lower.

- HCPs should evacuate any MWD heat stroke casualty to veterinary facilities on an URGENT basis if feasible.

Monitor and Treat Concurrent or Developing Problems[7,10,11]

- Shock is common in MWDs with heat stroke. Manage shock (See Chapter 6, Figure 33). Monitor blood pressure, lactate clearance, clinical assessment of perfusion, and assessment of volume status until the MWD is evacuated.

- Glucose, acid-base, and electrolyte abnormalities are common. If able, monitor blood glucose and venous blood gas analyses every 6-12 hours. If concurrent pulmonary abnormalities are present, monitor arterial blood gas analysis (or surrogates such as pulse oximetry and capnography). Supplement maintenaced IV fluids with dextrose to 5% and with KCl at 20 mEq/L routinely to maintain normoglycemia and normokalemia.

- Hypercoagulable and consumptive coagulopathic states (e.g., DIC) are common. Gastrointestinal hemorrhage is common during recovery, and may be present on admission. FFP or canine serum albumin may be necessary; however, these are not available to HCPs, and HCPs must not give human FFP or human serum albumin to dogs. Coagulation testing for MWDs will be problematic for HCPs, as analyzers for human blood will not provide accurate results for canine blood. HCPs should monitor the MWD and CBCs (if available) for evidence of thrombocytopenia (petecchiae, ecchymoses, low platelet count). HCPs should monitor for signs of clotting abnormalities (e.g., hematoma formation, intracavitary bleeding, epistaxis, hematuria). MWDs rarely require whole blood or pRBCs to treat complications of heat-induced illness; frozen plasma or fresh frozen plasma may be necessary in severe cases. HCPs must never give human blood to dogs. URGENT evacuation to veterinary facilities is critical to survival of MWDs that develop bleeding disorders, as veterinary personnel can facilitate canine blood product collection and administration.

- Cardiac arrhythmias, especially ventricular arrhythmias, are common, but rarely require intervention. Perform continuous or intermittent ECG monitoring. Treat ventricular arrhythmias only if causing hemodynamic compromise, using lidocaine (2 mg/kg IV bolus, then 50-75 mcg/kg/min CRI).

- Vomiting and diarrhea are typical. Diarrhea is often hemorrhagic. Start systemic antibiotic therapy (See Chapter 14) for any MWD with hemorrhagic diarrhea. Start famotidine therapy (1 mg/kg IV, IM, or PO q12h) for any MWD with heat stroke. Treat nausea and vomiting with ondansetron (1 mg/kg, IV or PO, q12-24h). Add sucralfate (1 gram PO q8h) for any MWD with hematemesis. Allow food and water once vomiting has resolved. Hygiene is critical, and bedding should be changed as needed; shave long tail hair and wrap tails to minimize soiling.

- Renal insufficiency is uncommon, but possible. Maintain urine production at 1-2 ml/kg/hour. Monitoring urine output in males will be difficult without canine-specific urethral catheters; use estimates of voiding or weigh absorbent pads or blankets to estimate urine output. Alternatively, in male dogs, adapt a 10- or 12-Fr

suction catheter (ubiquitous in trauma bays) by removing the control valve end, aseptically inserting the remaining catheter into the urethra to the level of the urinary bladder, and connecting the distal end to a sterile empty IV bag or closed collection system by way of an adapter.

- Treat seizures with a benzodiazepine (diazepam or midazolam, 0.3 mg/kg; IV, IN, rectally) as needed, up to 3 doses over 2 hours. If seizures continue, give phenobarbital (15-20 mg/kg total dose, divided into 4 doses and given IV every 30-60 minutes as needed to control seizures) and start oral phenobarbital (2.5 mg/kg PO q12h) 12 hours after last IV dose. Treat any MWD with stupor or coma with mannitol on admission (1.5 grams/kg, IV, over 30 minutes) and repeat every 4-6 hours for up to 2 additional doses). CNS abnormalities typically resolve with mild or moderate cases of heat stroke. Cortical blindness is common and usually resolves over a period of several days.

Prognosis: Nucleated Red Blood Cells, Heat Injury Severity Scoring System

- A study in 40 dogs[12] demonstrated that 90% of dogs presenting with heatstroke had increased peripheral nucleated red blood cells (nRBC) at presentation, with a cut-off point of 18 nRBC/100 leukocytes corresponding to a sensitivity and specificity of 91 and 88%, respectively, for death. Dogs with nRBC above this cut-off were significantly more likely to have life-threatening complications such as kidney failure and disseminated intravascular coagulopathy, as well. Thus, rapidly screening for the presence of nRBC may be useful to confirm clinical suspicion of heatstroke, and guide aggressiveness of therapy and monitoring.

- A severity scoring system[10] has been validated in dogs with clinical heat stroke that may prove useful to gauge severity of injury and prognosis based on key clinical and laboratory parameters noted within the first 24 hours of admission. Parameters useful to measure include heart rate, blood glucose, and coagulation tests. Clinically, the presence of obesity, acute collapse, shock, seizures, altered mental status, coagulopathy, acute kidney injury, and acute lung injury are documented risk factors for death. While calculating this score is beyond the scope of practice for HCPs, it is key to recognize those parameters and conditions that are significantly associated with outcome and complications, and to document these results, as this guides the aggressiveness of therapy and monitoring.

TABLE 12. MWD HEAT INJURY PROTOCOL[5-10]

PHASE	CLINICAL SIGNS	
MILD (Stress)	Controlled panting, excessive thirst, discomfort	Dehydration typically accompanies heat injury --> treat dehydration and monitor for shock
MODERATE (Exhaustion)	**UN**controlled panting, weakness, ataxia, anxiety, petecchiae/ecchymoses	
SEVERE (Stroke)	Moderate signs, ***PLUS*** CNS signs, collapse, shock	

TREATMENT OF MILD HEAT INJURY

1. Cease work
2. Remove from source of heat (move to shade or air-conditioned area if possible, use fans if available)
3. Offer cool water in small increments frequently
4. Monitor temperature q 15-30 min to ensure mild injury doesn't progress; perform serial physical exams

TREATMENT OF MODERATE AND SEVERE HEAT INJURY -- ANY DOG WITH TEMPERATURE >105^0 F

1. Immediately soak the dog's skin with water – Saturate to the skin!!
2. Continue soaking until body temperature is reduced to <105^0 F.
3. Start IV fluid therapy
4. Follow SHOCK RESUSCITATION PROTOCOL if dog is in shock (See Chapter 6, Figure 33)
5. Give IV fluids at 3-5 mL/kg/hr if not in shock
6. Triage the patient based on severity of injury
7. Protect the airway (intubate or tracheostomy *prn*), treat dehydration or shock, support ventilation *prn*
8. Be prepared to support/correct REBOUND HYPOTHERMIA
9. Dog may be hypothermic on arrival or develop hypothermia during treatment
10. DO NOT USE cold or iced IV fluids, surface cooling with ice, or ice water immersion

REDUCE cooling efforts once the body temperature is <105^0 F. Dry the hair, stop fans, increase room temperature, etc.

CEASE cooling efforts once the body temperature is <103^0 F to prevent rebound hypothermia. Actively warm the dog if temperature is <100^0 F

PROVIDE INTENSIVE MONITORING AND MANAGEMENT

Maintain NORMOTENSION -- Target MAP of >65 mmHg or Systolic BP >90 mmHg

Maintain VENTILATION -- Target RR of 8 - 10 bpm -- Target E_TCO_2 25 - 60 mmHg

Maintain OXYGENATION -- Target SpO_2 >95% with supplemental oxygen *prn*

CONTROL SEIZURES

MIDAZOLAM or DIAZEPAM	0.3 mg/kg -- IV, IO, or INTRANASAL *prn*

TABLE 12: MWD HEAT INJURY PROTOCOL[5-10] (continued)	
MANAGE CEREBRAL EDEMA	
MANNITOL	1 - 2 grams/kg -- IV over 30 min
and	
DEXAMETHASONE	0.5 mg/kg IV ONCE
…or…	
METHYLPREDNISOLONE	30 mg/kg -- IV -- ONCE
CONTROL PATHOLOGIC VENTRICULAR ARRHYTHMIAS	
LIDOCAINE CRI @ 50 - 75 mcg/kg/min	CORRECT H's and T's FIRST

CONTROL HYPOGLYCEMIA	MANAGE ANCILLARY PROBLEMS
▪ SUPPLEMENT IV fluids with 5% dextrose ▪ MONITOR blood glucose q4-6h ▪ AVOID intensive glucose titration	▪ Anti-emetics + gastrointestinal protectants ▪ Potassium Supplementation ▪ Mobility

Hypothermia and Cold Injuries

Hypothermia in MWDs may be caused by exposure to low environmental temperatures (primary hypothermia), or low body temperature due to trauma, toxicity, underling illness, or anesthesia and surgery (secondary hypothermia).[1] Most commonly, HCPs will be presented with dogs suffering secondary hypothermia.

Classification of Hypothermia

MWDs with primary hypothermia can apparently tolerate much more severe hypothermia than MWDs with secondary hypothermia, and adverse effects due to hypothermia have been reported in dogs with secondary hypothermia at significantly closer-to-normal temperatures than patients with primary hypothermia.[1]

- Primary hypothermia is classified as mild (90-99° F), moderate (82-90° F), severe (68-82° F), or profound (less than 68° F).
- Secondary hypothermia is classified as mild (98-99.9° F), moderate (96-98° F), severe (92-96° F), or profound (less than 92° F).

Management of Hypothermia

- Warm hypothermic MWDs rapidly but carefully. Anticipate possible complications. Cardiovascular support (principally IV fluid therapy), management of co-existing problems, and prevention of rewarming complications are necessary (See Table 13).
- Rewarm MWDs at a target rate of increase of 2-4° F per hour.
- Use a combination of methods based on the severity of hypothermia and the MWD's status.
- Rewarm MWDs with mild hypothermia and normovolemia using passive surface warming. Apply external blankets, towels, or other devices to prevent heat loss while the animal 'self-generates' heat. These measures will not be effective as sole measures if shivering is absent.[1]
- Rewarm MWDs with moderate hypothermia using active surface warming.
  - Use externally-applied heat sources such as forced-air devices, warm water bottles, or warm-water circulating heating pads to provide heat to offset the patient's inability to generate heat.
  - Provide IV fluid volume support to maintain normotension and prevent rewarming shock (See Chapter 6, Figure 33).

- Apply heat to the thorax and abdomen, and not the extremities, as this avoids peripheral vasodilatation and prevents the decreased thermoregulatory response seen when extremities are warmed, both of which contribute to persistent hypothermia and "afterdrop."[1,5]

- Rewarm MWDs with severe or profound hypothermia using active core warming.
  - Always use active surface warming concurrently with active core warming.[1]
  - Use warmed IV fluids. The temperature of intravenous fluids should not exceed 108° F to avoid injury to cellular components of the peripheral blood.[1,5]
  - If the MWD is intubated and warming humidifiers are available on anesthesia circuits, use warmed inhaled air.
  - Given potential complications with use, HCPs should not use warm peritoneal or pleural lavage or urinary bladder or rectal lavage with warmed fluids.
  - Warm hypothermic MWDs to a temperature of 98.5° F, and then cease use of all warming methods except passive warming, while providing blood volume support (i.e., IV fluids) at relatively moderate rates to avoid volume overload (10-15 mL/kg/h) that is possible due to earlier cold diuresis [1,5] in hypothermic MWDs being rewarmed.

Complications Related to Hypothermia

- It is most important for the HCPs to recognize potential problems rather than specific temperatures at which to expect these problems.
- Hyperglycemia is common in mild and moderate hypothermia; specific measures to reduce blood sugar are seldom necessary. Hypoglycemia can develop in severely hypothermic patients, and dextrose supplementation (5% in IV fluids) is recommended empirically.
- Hypokalemia is common in mild-to-moderate hypothermia, and supplementation is necessary (KCl in IV fluids, 20 mEq/L) empirically. Hyperkalemia is reported in severe hypothermia; specific measures (e.g., insulin-dextrose administration, bicarbonate administration) may be necessary if potassium is >7-8 mmol/L. Check electrolytes, if able.
- Metabolic and respiratory acidosis are reported in most types and degrees of hypothermia; these typically correct with fluid therapy and patient warming.
- Hemostatic defects are common. MWDs are commonly in a hypocoagulable state with prolonged clotting times, and platelet abnormalities are also noted. Monitor for bleeding diasthesis. Given the inability to correct coagulopathies and thrombocytopenias in MWDs in the deployed setting, any MWD with evidence of bleeding should be evacuated URGENTLY to a veterinary facility.
- Tachycardia and hypertension are common in mild-to-moderate hypothermia. As hypothermia worsens,

bradycardia and hypotension develop, and other cardiac arrhythmias may develop. Monitor continuous ECG and blood pressure. Avoid giving drugs, to include anti-arrhythmic agents, until the body temperature is >90°, as drugs are believed ineffective at temperatures below this.[1,5]

- ***HCPs must be aware that measures to correct hypothermia can actually cause complications to develop, such as "afterdrop" and "rewarming shock;" thus, careful warming and close monitoring are essential when managing hypothermic patients.***[3,5]
  - "Afterdrop" is the continued decrease in core temperature as warming is provided, due to the return of cold peripheral blood to the central circulation. To prevent "afterdrop," it is important to warm the patient's trunk (chest and abdomen), not the extremities.
  - "Rewarming shock" develops with excessively rapid warming and is due to the sudden development of systemic vasodilatation. This vasodilatation causes hypotension at a time when the circulatory system may not be able to react. The systemic hypotension is aggravated by the increased metabolic demand that develops as hypothermic patients are rewarmed, which increases the demand for perfusion. To prevent or reduce "rewarming shock," IV fluid therapy must be provided and assessment of volume status (e.g., serial body weight measurement, clinical signs of hydration), systemic blood pressure, and tissue perfusion (e.g., evaluation of CRT, lactate clearance, change in mentation, urine output) must be monitored carefully.

Cold-induced Injury

Cold-induced injuries include non-freezing and freezing injuries, typically to an extremity, and tend to be related to geographic location (i.e., freezing climates) and use of the animal (e.g., search dogs).

Non-freezing Injury

Non-freezing injuries typically involve the extremities, occur despite the tissue not actually freezing, and are commonly due to prolonged cold exposure. In humans, common terms to describe these types of injuries are "chilblains" and "immersion foot" or "trench foot;" similar terms are not used in veterinary medicine.

With non-freezing injuries, extremities (ear pinnae, paws, tail tip, scrotum) are exposed to cold temperatures above freezing for prolonged periods (>12 hours), causing intense erythema of the skin, pain, and pruritus. If skin is exposed to damp conditions or submerged and exposed to cold, tissue edema and maceration may also develop.

Treatment of non-freezing cold injuries involves removing the MWD from the cold environment and passively warming the affected tissues slowly. Passive warming of non-freezing injuries can be accomplished by moving the MWD to a warm room (e.g., hospitalize, indoor facility) and gently wrapping the patient or affected body part in warm blankets or towels.

TABLE 13. MANAGEMENT OF HYPOTHERMIA IN MWDS

1. Warm rapidly but carefully.
   a. Increase the body temperature by 2-4° F per hour.
   b. Warm to a temperature of 98.5^0 F, and then cease use of all warming methods except passive warming.
2. **Mild hypothermia, adequate blood volume** – Warm using passive surface warming (wrap MWD in blankets or towels; hospitalize in warm environment).
3. **Moderate-to-severe hypothermia;** mild hypothermia with inadequate blood volume.
   a. Warm using active surface warming (use of externally-applied heat sources such as forced-air devices, warm water bottles, non-electric heating pads, or dryers)
   b. Apply heat to the thorax and abdomen, and not the extremities.
   c. Perform passive warming as above.
4. **Severe-to-profound hypothermia**
   a. Warm using active core warming (heat inhaled air provided by endotracheal tube, warm intravenous fluids).
   b. Perform active and passive warming as above.
5. Provide cardiovascular support.
   a. Provide intravenous fluids at relatively moderate rates (2-3 times maintenance rates, or 2-10 mL/kg/h) until normothermic.
   b. Once resuscitated and stabilized, provide continued intravenous fluids.
   c. Provide oxygen supplementation for severe-to-profound hypothermia to reduce risk of cardiac arrhythmias.
6. Anticipate and manage complications.
   a. Perform continuous ECG monitoring, and treat malignant arrhythmias using lidocaine 2 mg/kg IV bolus followed by lidocaine CRI 50-75 mcg/kg/min as needed. ***Do not treat arrhythmias until body temperature >90°.***
   b. Monitor for glucose, electrolyte, and acid-base abnormalities every 6-12 hours.
   c. Monitor platelet count and coagulation parameters every 6-12 hours.
   d. Provide analgesia as needed (See Chapter 16).
   e. Perform continuous or intermittent blood pressure monitoring, lactate clearance, changes in mentation, and urine output to monitor for "rewarming shock."
   f. Perform continuous temperature measurement, to monitor for correction of hypothermia and "afterdrop."

Freezing Injury

Freezing injury, or "frostbite," is the development of cold injury in which tissues actually become frozen, with crystallization (ice formation) of tissue and cell water. Frostbite is seen at environmental temperatures below 32° F and primarily affects the distal extremities, ears, nose, scrotum, and tail. Frostbite varies in severity from superficial (1st degree frostbite) to deep injury (4th degree frostbite).

Clinical signs of superficial frostbite (1st and 2nd degree frostbite) include a grey-to-white, waxy appearance of affected skin; blistering of affected skin may be present with 2nd degree frostbite. Clinical signs of deep frostbite (3rd and 4th degree frostbite) include involvement of the entire epidermis, but no subcutaneous tissues (3rd degree) to involvement of subcutaneous tissues, to possibly include muscle and bone (4th degree frostbite). Tissues affected with deep frostbite may be black and friable. In all cases of frostbite, pain may be intense, especially during rewarming of tissues.

Management of MWDs with freezing injury is summarized in Table 14 on the next page. Treatment of frostbite involves rapid warming of affected tissues, overall patient management (e.g., treatment of whole-body hypothermia,
trauma, or shock as appropriate), analgesia, and protection of affected tissues.

- Affected tissues may be warmed by immersion in a water bath that is 104-108° F for at least 20 minutes or until thawing has occurred, or by wrapping the affected tissue with warm, wet towels for 15 to 20 minutes, changing the towels every 5 minutes.
- Do not use dry heat to warm tissues, and never rub or massage the tissues, as further injury may occur.
- Provide systemic analgesia (See Chapter 16), as frostbite is extremely painful.
- Protect the affected tissues by applying loose protective bandages, minimizing movement (confine to a cage), and attaching a bucket-collar device (See Figure 21 and Figure 22) to prevent self-trauma.
- Antibiotic use is not recommended.
- Aseptically aspirate large blisters that develop.

TABLE 14. MANAGEMENT OF FREEZING INJURY (FROSTBITE) IN MWDS
1. Treat whole-body hypothermia, trauma, or shock as directed in supporting chapters. 2. Provide systemic analgesia (See Chapter 16). 3. Warm frozen tissues gently and slowly, using 1 of 2 methods: a. Immerse in a water bath that is 104° to 108° F for at least 20 minutes or until thawing has occurred. b. Wrap with warm, wet towels for 15 to 20 minutes, changing the towels every 5 minutes. ***NOTE: Do not use dry heat or rub or massage tissues to warm tissues.*** 6. Apply loose protective bandages. 7. Minimize movement (confine to a cage). 8. Apply a bucket to the collar to prevent self-trauma. 9. Aseptically aspirate large blisters that develop. Do not use empiric antibiotics. 10. Manage open, infected, or necrotic wounds (See Chapter 14).

Snake and Insect Envenomation

Insect and snake envenomation of dogs is possible in deployed settings (See Table 15). This chapter focuses on the CENTCOM AOR exclusively. Refer to local guidance for other geographic areas.

- Specific treatment with geographic area-specific antivenin is optimal for patients with moderate-to-severe clinical signs.
- Although data are limited, antivenin decreases morbidity and may reduce mortality (especially for bites to the trunk and upper limbs, which have the highest mortality rates).[1-3]
- Antivenin is typically only available in select Role 2 and Role 3 facilities because antivenin use – for humans and dogs – is highly regulated and governed by theater policy. The CENTCOM Policy for Snake and Scorpion Antivenins, which provides regulatory guidance for antivenin management, use, and reporting, is the primary reference to guide use of snake and scorpion antivenin in dogs.[4]
- Antivenins, especially those that contain whole immunoglobulin components, must be used with caution, due to the potential to induce allergic reactions.[1-3,5,6] Although dosing in dogs is empiric, if used, antivenins should be given to effect to control clinical signs.

Insect Envenomation

Insect envenomation typically causes local pain, erythema, and swelling (angioedema or urticaria). Some insect venoms cause a locally extensive wound that often take several days to manifest, while others may cause systemic anaphylaxis.

Venomous Scorpions

Venomous scorpions that typically induce severe clinical signs include the Arabian or Asian Fat-Tailed Scorpion (*Androctonus amoreuxi*), the African Ground Scorpion (*Hottentotta alticola*), and *Hemiscorpius lepturus* (no common name).

Venomous Spiders

Venomous spiders that typically induce severe clinical signs include the Mediterranean Black Widow (*Latrodectus tredecimguttatus/lugubris*) and the Tarantula or Wolf spider (*Lycosa signoriensis*). Note that sopulgids (Camel spiders) are NOT venomous, but may cause a painful bite.

Supportive Care for Scorpion Stings and Spider Bites

- Coordinate MEDEVAC (Urgent) directly to appropriate medical facilities where antivenin is stored. Remote sites should request overfly (bypass the local MTF/VTF) directly to appropriate facilities.
- Ensure a patent airway and provide supplemental oxygen and ventilation, as needed.
- Place an IV catheter and obtain a CBC, blood chemistry panel, and urinalysis.
- Start crystalloid fluids IV to maintain hydration and perfusion and to facilitate diuresis of toxin. Fluid rate should be 3 mL/kg/hr for 12 hours, then reduce to 2 mL/kg/hr for another 12 hours, pending patient improvement.
- Administer 50 mg diphenhydramine IM and wait 30 minutes after initial dose before administering antivenin. Repeat diphenhydramine every 8 hours for a total of 3 doses.

  NOTE: MWD handlers may have been issued diphenhydramine and may have initiated therapy before presentation. Do not give diphenhydramine IV because it can cause severe hypotension in dogs.

- Manage any open wounds that develop (See Chapter 14).
- Treat pain if noted (See Chapter 16). NOTE: Do not treat with NSAIDs, given the propensity for envenomated dogs to develop coagulopathies and thrombocytopenia and thromobocytopathia.
- If systemic anaphylaxis is suspected based on the history and clinical signs (weakness, peracute vomiting or diarrhea, collapse, or hypotension), treat the MWD as above, and treat with IV fluid therapy as for shock (See Chapter 6, Figure 33) and give epinephrine (0.5-1 mg per dog, IM or IV; repeat if necessary every 20-30 minutes).
- Hospitalize the patient and provide supportive care until resolved or evacuated.

Antivenom Use for Scorpion Stings and Spider Bites

Scorpion Stings

Administer Saudi Polyvalent Scorpion (Equine) $F(ab)_2$ if the specific scorpion is identified as one of those listed above and if systemic clinical signs of evenomation are present. Dosing is empiric: Initially, dilute 5 of the 1 mL ampules in 100 mL 0.45% saline and infuse IV over 60 minutes.

Spider Bites

Antivenin is only available for Black Widow spider bites. Administer Antivenin Latrodectus mactans for witnessed Black Widow spider (*Latrodectus tredecimguttatus/lugubris*) bites and with systemic evenomation clinical signs. Dosing is empiric: Reconstitute 1 vial, dilute in 100 mL 0.45% saline, and infuse IV over 60 minutes.

Snake Envenomation

- Clinical signs of bites by venomous snakes can vary tremendously, principally depending on the type of snake involved, location and number of bites, and the amount of venom injected. HCPs should become familiar with indigenous snakes in deployed areas and seek guidance on specific management recommendations in preparation for deployments. Information on indigenous venomous snakes in each AO can be found in the Veterinary Medical Threat Brief from the MD(VSS) or Medical Brigade Staff Veterinarian.
- Vipers and elapids are the most common venomous snakes of concern in the CENTCOM theater (See Table 15).
- In general, snakebites by most venomous vipers cause severe pain, variable degrees of local swelling that may spread, and varying degrees of local tissue necrosis. Many MWDs will also develop systemic signs of pain. Some dogs will develop life-threatening complications of envenomation, but this is uncommon. Generally, clinical experience shows that most MWDs bitten by vipers on the face or lower leg will survive, with or without antivenin treatment. Dogs bitten on the upper limb or torso, however, have markedly increased mortality rates. It is prudent to recommend that any MWD bitten by a venomous snake be evacuated URGENTLY for optimal management. Follow guidelines below while coordinating evacuation.
- Unwitnessed envenomation is common. The presence of fang marks does not necessarily mean that envenomation has occurred – "dry bites" are common. Conversely, envenomation may have occurred without obvious puncture wounds evident.
- Injection of venom typically causes marked localized swelling and edema, intense local pain, and discoloration of the surrounding tissues due to necrosis, with oozing of venous blood.
- Systemic signs frequently observed include pain, lethargy, vomiting, and weakness. Many MWDs will develop laboratory evidence of thrombocytopenia and coagulopathy (decreased platelet count, prolonged coagulation times) but true spontaneous hemorrhage is rare.

Supportive Care for Venomous Snake Bites

- Coordinate MEDEVAC (Urgent) directly to appropriate medical facilities where antivenin is stored. Remote sites should request overfly (bypass the local MTF/VTF) directly to appropriate facilities.
- Hospitalize any MWD with history of or signs suggesting envenomation for at least 12 hours to monitor progression.
- Ensure patent airway, provide supplemental oxygen, and ventilation, as needed.
- Place an IV catheter and obtain a CBC, blood chemistry panel, and urinalysis.
- Start crystalloid fluids IV to maintain hydration and perfusion and to facilitate diuresis of toxin. Fluid rate should be 3 mL/kg/hr for 12 hours, then reduce to 2 mL/kg/hr for another 12 hours, pending patient improvement.

- Administer 50 mg diphenhydramine IM initially, and then once every 8 hours for a total of 3 doses. Wait 30 minutes after initial dose before administering any antivenin.

  NOTE: MWD handlers may have been issued diphenhydramine and may have initiated therapy before presentation. Do NOT give diphenhydramine IV; it can cause severe hypotension in dogs by this route.

- Manage any open wounds that develop (See Chapter 14).
- Treat pain if noted (See Chapter 16). NOTE: Do not treat with NSAIDs, given the propensity for envenomated dogs to develop coagulopathies.
- ***Do NOT use tourniquets, ice packs, heating, or local vasoconstriction (***e.g., injection of epinephrine locally) in an attempt to slow venom spread.
- Confine MWDs to minimize venom distribution.
- If systemic anaphylaxis is suspected based on the history and clinical signs (weakness, peracute vomiting or diarrhea, collapse, or hypotension), treat the MWD as above and also, treat with IV fluid therapy as for shock (See Chapter 6, Figure 33), and give epinephrine (0.5-1 mg per dog, IM or IV; repeat if necessary every 20-30 minutes).
- Treat mild envenomations (signs localized to face or lower limb that do not progress or progress slowly) with analgesics (See Chapter 16), diphenhydramine (2-4 mg/kg IM q8h), and IV fluid therapy (3-5 mL/kg/h for at least 12 hours, then reduce to 2-3 mL/kg/h for another 12 hours). See recommendations for antivenin use.

Antivenom Use for Viper and Elapid Envenomation

- Treat moderate-to-severe envenomation (rapidly progressive signs originating on the lower limb or face, any MWD with systemic signs, and any MWD with upper limb or torso bites) with analgesics (See Chapter 16), diphenhydramine (2-4 mg/kg, IM, q8h), IV fluid therapy using the guidelines recommended for shock therapy initially (See Chapter 6, Figure 33), and antivenin (if available) following the recommendations that follow. Monitor closely for progression.
- For suspected or unwitnessed envenomation by an unknown species of snakes, use the Razi Polyvalent Snake Antivenin, as it has the broadest spectrum of antivenin activity for the majority of venomous snakes in theater. Intradermal testing for potential allergic reaction is unreliable in clinical cases; do not delay antivenin administration to perform this testing. Emergency interventions should be initiated as needed to treat anaphylaxis.
  - Dilute 2 ampules of Razi Polyvalent Snake Antivenin in 100 mL 0.45% saline and infuse IV over 60 minutes.
  - Dose “to effect” with dosing targeted to visible reduction in severity and progression of swelling and pain locally at the site of envenomation, and to improve the dog’s comfort.
  - Be prepared to administer 1-2 additional ampules over an hour if swelling continues to increase or spread, pain locally and systemically is not abated, or the patient’s overall condition deteriorates. Additional antivenin may be needed if clinical signs persist, worsen, or recur. Antivenin is effective up to 24 hours after envenomation; consider use even if there was delay in evacuation to the facility for care.

- For witnessed envenomation by vipers or elapids for which $F(ab)_2$ antivenin is available, use Saudi Polyvalent Antivenin monotherapy, or a combination of Saudi FAVIREPT Polyvalent Antivenin and the Haffkine/ Vinsbio (Indian) Antivenin.
  - Dilute 4 of the 10 mL ampules of Saudi Polyvalent Snake Antivenin $F(ab)_2$ in 350 mL of 0.45 % saline and infuse IV over 60 minutes.
  - Alternatively, dilute 2 of the 10 mL ampules of Saudi FAVIREPT Polyvalent $F(ab)_2$ in 250 mL 0.45% saline and infuse IV over 60 minutes, PLUS give 1 of the 10 mL ampules of Haffkine/Vinsbio (Indian) in 500 mL 0.45% saline infused IV over 60 minutes.
- Treat presumed adverse effects of antivenin (increased temperature, restlessness, panting, vomiting, urticaria or angioedema, weakness, collapse, hypotension) by temporarily slowing or stopping the antivenin infusion and giving diphenhydramine (2-4 mg/kg, IM). Consider epinephrine (0.5-1.0 mg per dog, IM or IV) if signs of shock develop.

NOTE: Use of fresh frozen plasma (FFP) is controversial for snake envenomation. Currently canine FFP, if available, should only be considered in cases of severe systemic coagulopathy with active bleeding.

TABLE 15. VENOMOUS SNAKES, CENTCOM AOR

Location	Type	Common Name	Scientific Name	1st Choice Antivenin	2nd Choice Antivenin
Afghanistan	Viper	Puff adder	*Bitis arietans*	Saudi	FAVIREPET
Afghanistan	Viper	Saw-scaled vipers	*Echis spp*	Razi	Saudi, FAVIREPT, Haffekine/Vinsbio
Afghanistan	Viper	MacMahon's viper, Asian sand viper	*Eristocophis macmahoni*	Razi	Saudi, FAVIREPT
Afghanistan	Viper	Haly's pit viper	*Gloydius spp*	Razi	None
Afghanistan	Viper	Levantine vipers	*Macrovipera lebetina subspp*	Razi	None

Blast, Burn and Crush Injuries

With the increased use of improvised explosive devices, blast injury is not uncommon in MWDs. However, there is little definitive clinical information available for managing blast injury in dogs, so recommendations are similar to management for human patients. Burn and crush injuries are less common, but may be encountered.

Blast Injury

Be prepared to provide care for MWDs exposed to bomb blasts and other explosions. Recognize that blast injuries may be subtle or occult for days, with MWDs appearing stable on initial evaluation. Figure 43 (next page) provides the recommended general approach to assessing MWDs exposed to blast.

Blast Injury Mechanisms[1-3]

Blasts produce injury through primary effects of the blast overpressure wave, secondary injury due to penetrating objects displaced by the explosion impacting victims, tertiary injury due to victims physically being displaced into objects, and quaternary injury due to complications resulting from any combination of injury from primary, secondary, or tertiary injuries or unrelated to these mechanisms.

Initial Management of Blast Injuries

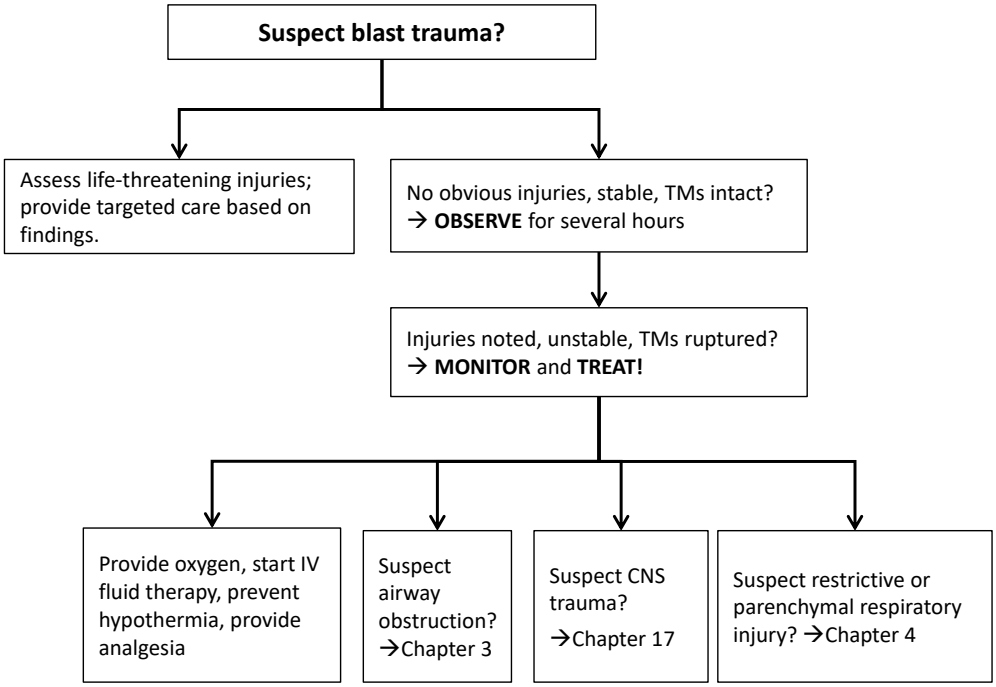
Generally, the approach to blast-injured MWDs is the same as for any other type of trauma – FOCUS on life-threatening problems first, followed by targeted support based on findings, with emphasis on a detailed secondary evaluation and care as needed once the patient is stabilized.

During initial care, focus on those types of life-threatening injuries commonly seen with blasts, especially respiratory distress due to airway obstruction or trauma, pneumothorax, pulmonary contusions, and hemothorax; traumatic amputations or serious bleeding; hemoperitoneum; CNS trauma; air embolism; and shock.

While tympanic membrane (TM) rupture in and of itself is a minor injury, experience suggests that it is a marker of more severe systemic injury, and patients with TM rupture should be observed carefully for signs suggesting the development of other injuries.[2-3] The absence of TM rupture, however, does not exclude potentially life-threatening internal injuries, based on recent data from humans exposed to blasts.[3]

Recognize delayed onset of clinical signs. Many injuries from blasts may not manifest for many hours, to include pulmonary contusions, “blast lung,” concussions and mild TBI, and bowel hemorrhage with perforation and peritonitis. Serial monitoring is critical to detect early signs of impending decompensation due to these delayed problems. Any MWD exposed to blast should be evacuated to a veterinary facility as soon as possible for detailed evaluation and observation. If evacuation is not possible or is delayed, hospitalize in the MTF for 12-24 hours for close observation.

Figure 43. General Approach to Military Working Dogs Exposed to Blasts.



Suspect blast trauma?
Assess life-threatening injuries; provide targeted care based on findings.
No obvious injuries, stable, TMs intact? → **OBSERVE** for several hours
Injuries noted, unstable, TMs ruptured? → **MONITOR** and **TREAT!**
Provide oxygen, start IV fluid therapy, prevent hypothermia, provide analgesia
Suspect airway obstruction? →Chapter 3
Suspect CNS trauma? →Chapter 17
Suspect restrictive or parenchymal respiratory injury? →Chapter 4

Burn Injury

Burn injuries in MWDs are typically caused by fires, motor vehicle mufflers, stoves, caustic chemicals, or explosions. While uncommon, these injuries can cause not only severe pain and complicated local wounds, but also result in serious metabolic abnormalities and systemic infection that can lead to life-threatening compromise.

Burn Classification in MWDs[4-6]

Burns affecting dogs are physically similar to those in humans. Hair may need to be carefully clipped over burned areas for adequate assessment. Superficial burns are red and painful, similar to sunburn, involving the outer layer of the epidermis. Superficial partial-thickness burns are red or mottled, with epidermal sloughing, fluid leakage, swelling, and extreme hypersensitivity (pain), involving the epidermis and variable amounts of dermis. Hair should not easily pull out. Deep partial-thickness burns are black or yellow-white and hair follicles are
destroyed, and the skin surface is dry. These burns are generally less painful, as nerve endings are destroyed. If any hair remains, it will pull out easily. Full-thickness burns are black, dry, and leathery. These burns have destroyed the epidermis and dermis and expose underlying connective tissue, muscle, and bone. Any eschar that forms is painless.

Inhalation Injury

Burn patients may have significant inhalation injury. Clinical signs of inhalation and pulmonary injuries may not manifest for several hours. Clinical signs of inhalation injury include stertor or stridor, harsh cough or upper airway sounds, coughing, production of dark sputum, tachypnea, and respiratory distress. MWDs with inhalation injury should be observed closely for need for orotracheal intubation or (uncommonly) tracheostomy to manage the airway. Intubate or perform tracheostomy for any MWD with observed respiratory distress or if in doubt about the patency of the airway (See Chapter 3).

Estimation of Total Body Surface Area (TBSA) Burn Extent in Dogs

Determine the severity of the burn once the MWD has been resuscitated and stabilized. General characteristics of the wound that are important to examine include color, texture, presence or absence of pain, moistness, and extent of swelling, if present.

Estimate the percent of the total body surface area (TBSA) that is burned by using a modification of the "Rule of 9s" used for humans:[4]

ADD the estimated percent of burn from EACH of the following body areas:

- Head and neck (H/N) – 9%
- Chest (C) – 18%
- Abdomen (A) – 18%
- Each forelimb (L FL, R FL) – 9%
- Each hindlimb (L HL, R HL) – 18%

TBSA = H/N + C + A + L FL + R FL + L HL + R HL. For example, the estimated TBSA burn for a dog with burns to the chest and abdomen and left forelimb would be 18% (chest) + 18% (abdomen) + 9% (L FL) = 45%.

The percent TBSA is important in assessing severity, anticipating problems, and determining prognosis. Patients with TBSA >20% often have severe metabolic problems (e.g., hypovolemic shock, albumin and electrolyte losses, acidoses, renal failure); patients with TBSA >50% have a poor prognosis.[4] Any discussion of prognosis must take into consideration not only the TBSA but also the severity of burn. Note that initial evaluation of severity of burn wound may be inaccurate, as wounds often progress over a period of 3-7 days before completely manifesting ultimate severity.[4-5]

General Patient Management Recommendations[4-6]

- Monitor and treat for complications related to burn injury, to include shock, fluid losses, respiratory problems, and electrolyte abnormalities, see appropriate chapters. Stabilize the patient first. Manage pain using appropriate analgesics (See Chapter 16 and Table 17).
- Cool the burned skin using cool water (45-65° F) by immersion, application of compresses, or gentle spray for at least 30 minutes. Do not apply ice to any burned skin, as the vasoconstriction it causes may impede wound healing and may worsen the extent of tissue damage. Measure the patient's rectal or esophageal temperature frequently to monitor for and prevent hypothermia.

- Minimize potential contamination of burned skin. Wash hands thoroughly before handling patients; wear clean exam gloves (superficial burns, superficial partial-thickness burns) or sterile surgical gloves (deep partial-thickness burns, full-thickness burns); do not contact wounds with things such as personal clothing, stethoscopes, or other instruments or monitors; wear barrier protection when handling deep partial-thickness burns and full-thickness burns; change gloves and wash hands before handling other burn wounds and invasive devices on the same patient.
- Follow strict aseptic technique when placing invasive devices and use clean examination gloves whenever handling catheters, adapters, fluid lines, etc. Unless absolutely necessary, do not place invasive devices through burned skin. Provide antibiotic coverage using the guidelines in Chapter 14 only for MWDs presumed to be immunocompromised, with pneumonia or acute lung injury, or with sepsis or suspected sepsis.
- Provide excellent nursing care. Turn or rotate the MWD every 4 hours if recumbent, and perform Passive Range of Motion (PROM) exercises of all limbs except burned limbs every 4 hours. Provide soft, padded bedding. Prevent urine scalding and fecal soiling. Allow MWDs to eat and drink if able.

Specific Burn Wound Management Recommendations[4-6]

- Depending on severity and extent of burn, the patient may require daily heavy sedation or general anesthesia to allow debridement and management. Extreme care must be taken to monitor burn patients adequately during sedation or anesthesia (See Table 17).
- Superficial or superficial partial-thickness burns are generally managed with daily cool water lavage, followed by topical silver sulfadiazine cream application until healed or the wound worsens.
- Deep partial-thickness and full-thickness burns need varying degrees of daily wound debridement. This may be accomplished by use of conservative debridement, chemical debridement, or surgical debridement.
    - Conservative debridement of deep partial-thickness and full-thickness burns involves hydrotherapy using sterile saline lavage under light pressure or application of a wet-to-dry saline dressing under a light bandage for several hours, followed by removal of obvious necrotic or dead tissue using aseptic technique. Surgical debridement may be necessary in very deep or widespread wounds to more aggressively remove necrotic tissue; however, HCPs should not routinely perform surgical debridement – MWDs should be evacuated to veterinary facilities for this level of care.
    - Following debridement, apply silver sulfadiazine (SSD) cream, petrolatum, or hydrogel dressings in a thin layer directly on the wound and cover the burn with a non-adherent dressing (if the wound area is bandaged) or leave the burn uncovered (if bandaging is not permissible due to wound size or location).
- Bandage burn wounds if the burn area is amendable to application (i.e., the bandage can be placed without increasing patient discomfort, the burn area is relatively small, and the bandage will not increase the potential for wound injury). If there is any doubt about whether to bandage a burn wound or not, it is better to leave the wound unbandaged. In most cases, a wet-to-wet bandage is recommended to keep wounds moist and improve comfort. Change bandages at least daily or more often if wound exudate is excessive or the bandage becomes soiled.

TABLE 17. MANAGEMENT OF BURN WOUNDS IN MILITARY WORKING DOGS
Provide heavy sedation or general anesthesia to allow debridement and management, as necessary.
Superficial or superficial partial-thickness burns: ▪ Perform daily cool water lavage. ▪ Apply topical silver sulfadiazine cream after cool lavage.
Deep partial-thickness and full-thickness burns: ▪ Perform daily wound debridement as necessary: ▪ Perform hydrotherapy using sterile saline lavage under light pressure, or, ▪ Apply a wet-to-dry saline dressing under a light bandage for several hours, followed by removal of obvious necrotic or dead tissue using aseptic technique.
Protect burn wounds: ▪ Apply silver sulfadiazine cream in a thin layer directly on the wound. ▪ Apply a light protective bandage, if the burn area is amendable to application.

Crush Injury and Crush Syndrome

- Crush injury is defined as injury due to compression of extremities or other parts of the body that causes muscle swelling or trauma, with or without neurological or orthopedic problems in the body parts. Body areas most commonly involved are the limbs and torso.
- Crush syndrome develops when crush injury is extensive and prolonged, causing systemic manifestations. These systemic effects are due to traumatic rhabdomyolysis (muscle breakdown) and reperfusion syndrome (release of potentially toxic muscle cell components and electrolytes into the circulatory system) after sudden release of pressure over the crushed limb or torso. Acute hypovolemia and metabolic abnormalities are common and can be severe (even fatal), and myoglobinuria from trauma to muscles frequently may cause or exacerbate renal failure if untreated.
- Crush injuries and crush syndrome in MWDs are expected after building collapses, most frequently after natural disasters or explosions. In humans, the incidence of crush syndrome is 2-15% with approximately 50% of those with crush syndrome developing acute renal failure. Of those with renal failure, 50% need dialysis. Crush syndrome is rarely reported in animals.[7,8]

Pathophysiology

- Crush injury develops after muscle injury and muscle cell death. Three mechanisms are responsible for the death of muscle cells, to include direct cell lysis by the force of the crush; direct pressure on muscle cells causing muscle ischemia, development of anaerobic metabolism and lactic acidosis, and cell membrane disruption and leakage; and vascular compression or disruption, with loss of blood supply to muscle tissue.
- These mechanisms cause the injured muscle tissue to generate and release a number of substances that may be toxic in the general circulation. The crushing force actually serves as a protective mechanism, preventing these toxins from reaching the central circulation. Once the patient is extricated and the force is

released, reperfusion injury is prevalent due to release of toxic compounds and reactive oxygen species. Reperfusion injury may continue for as long as 60 hours after release of the crush injury.

- Other consequences of reperfusion include massive third spacing of fluids in crushed tissues, leading to hypovolemia and shock and exacerbating renal injury, and leading to compartment syndrome.

Clinical Presentation

Clinical signs of crush injury/crush syndrome include some or all of the following:

- Skin injury of the affected body part (may be subtle and less impressive than other signs)
- Limb swelling (may be delayed)
- Paresis or paralysis (may be mistaken as spinal cord injury)
- Loss of sensation (may mask the severity of underlying injury)
- Pain (typically becomes severe with reperfusion)
- Absent or weak extremity pulses
- Discolored urine due to myoglobinuria or hematuria or both
- Hypotension due to hypovolemia (dehydration, hemorrhage, third spacing of fluids) is commonly present and may be severe
- Massive third spacing (often causes or exacerbates compartment syndrome and renal failure)
- Metabolic abnormalities (hypocalcemia, hyperkalemia, and lactic acidosis)
- Clinical signs of compartment syndrome (severe pain in the involved extremity, pain on passive stretching of the involved muscles, decreased sensation to the affected limb)
- Renal failure (due to rhabdomyolysis and secondary myoglobinuric acute tubular necrosis).

Patient Management

- Treat MWDs, if possible, before and during extrication.
- Maintain a high index of suspicion, as MWDs with crush injury may present initially with few signs or symptoms. Delayed treatment leads to poor outcome.
- Most crush syndrome patients have an extensive area of involvement such as a lower extremity and/or the pelvis. It requires more involvement than just one paw. Also, the crushing force must be present for some time before crush injury syndrome can occur.
- The syndrome may develop in <1 hour in a severe crush situation, but usually it takes 4 to 6 hours of compression for the processes that cause crush injury syndrome to take place.
- The hallmark initial treatment for crush syndrome is IV fluid therapy before release of pressure and contin-

ued during extrication and evacuation. Place multiple IV lines, because the MWD will require large fluid volumes and there is a risk of catheter dislodgement during extrication. Normal saline is the initial fluid of choice. Avoid fluids with potassium.

- Once compression is removed, maintain aggressive fluid therapy. Specific guidelines for fluid volumes to administer are difficult to provide. As a starting point, use a rate of 3-5 mL/kg/hr to improve pulse quality, blood pressure (if possible to measure), CRT, and mentation. Try to estimate urine output – the goal is to maintain urine output >1-2 mL/kg/h.
- Alkalinization of the blood with bicarbonate (as is done for humans) is likely not going to be feasible. Thus, HCPs should focus on aggressive IV fluid therapy to correct dehydration and promote diuresis pending extrication and evacuation.
- Anticipate secondary complications. MWDs with crush injury should be treated initially as any other multiple trauma victim.
- Compartment syndrome is rare in dogs; this seems to be a much more common and more severe problem in humans, so extreme measures to control intracompartmental pressures like fasciotomy are unwarranted.
- Wounds should be cleaned and covered with sterile dressings in the usual fashion. Splint fractures if possible.
- Provide analgesia to any MWD with crush injury or crush syndrome (See Chapter 16).

CHAPTER 13

Long Bone Fractures

General Considerations

- Recognize and manage life-threatening problems FIRST. Fractures and muscle, tendon, or ligament injuries are rarely life threatening. Resuscitate and stabilize life-threatening problems first. Provide treatment to prevent further compromise to the fracture site and neurovascular structures and minimize infection risk.
- Recognize long bone fractures. MWDs with fractures will have varying degrees of lameness and will likely have limb deformity, swelling, pain, and loss of function. Open fractures are generally obvious, but pose greater risk of local and systemic infection and loss of function. See **Management of Open Fractures** in this chapter for specific guidance.
- Provide analgesia and confine the MWD. Any MWD with possible fractures or joint injury should initially be given parenteral analgesia, continued orally once stabilized (See Chapter 16). Any MWD with possible fractures should be confined to its kennel or small space at all times, with limited opportunities to go outside to urinate and defecate (three times daily as a minimum). Use a make-shift sling placed under the abdomen while walking patients outside. Analgesia and confinement may be the only treatment necessary or feasible, as noted below.

Long Bone Fractures and Joint Abnormalities of the Lower Limbs

HCPs should stabilize any suspected fracture or joint abnormality of the long bones distal to the elbow and knee (radius/ulna, tibia/fibula).

- Manage wounds as per Chapter 14 and then apply splints (e.g., SAM splints) to immobilize the fracture site, ensuring the joints above and below the fracture site are immobilized. Apply buttresses made of layers of cast padding or non-adherent dressing around footpads and any wounds. Apply about twice as much cast padding as is used for people. Generally, it is best to leave the nails of the middle two toes exposed, to allow monitoring for swelling.
- Cast application is not recommended, as cast pressure or friction sores are extremely common with MWDs and complicate recovery. MWDs tolerate splints and bandages poorly, so any MWD with a bandage or splint applied must wear a device to prevent self-mutilation or bandage removal (See Figure 21 and Figure 22).
- Splints and bandages generally need to be changed at least every other day. Change more frequently if soiled, wet, or loose.

Long Bone Fractures and Joint Abnormalities of the Upper Limbs

In MWDs, fractures of these bones are very difficult to immobilize, splints and bandages are poorly tolerated, and splints and bandages can actually increase fracture displacement, worsen fractures, and jeopardize neurovascular bundles. Key management principles are to provide adequate analgesia (See Chapter 16) and minimize movement to the maximal extent (kennel confinement except for limited leashed walks, using ancillary support).

- **HCPs without advanced orthopedic training and experience** generally should not attempt to immobilize fractures of the humerus, scapula, or femur.[1,2]
- **HCPs with advanced training and experience in orthopedics** (typically orthopedic surgeons, orthopedic PAs, splint technicians in Level 2 or higher facilities) may be capable, with written and/or verbal guidance from supporting veterinarians in constructing an appropriate Spica splint for humerus and femur fractures. In these instances, appropriate coaptation is safe, makes the patient more comfortable and consequently makes it easier and safer to transport a wounded MWD. With appropriate coaptation, the MWD is less likely to become agitated or aggressive every time it is bumped, moved, or moves about during manipulation and transport.

Open Fractures

Proper management of open fractures is essential. Open fractures should be treated as a medical emergency, once more pressing problems are addressed (See Table 18).[1,2]

Initial management of open fractures during resuscitation. While evaluating the entire patient and initiating life-saving therapy, take measures to protect the open fracture site:

- Do not attempt to reduce bone(s) protruding at fracture sites, as this drags contamination to the fracture site and may cause injury to the neurovascular bundle.
- Quickly remove any large gross contaminants from the wound (e.g., leaves, rocks, stick fragments), but do not attempt to clip the hair or cleanse the wound at this point.
- Cover the fracture and wound with sterile non-adherent dressing and apply a light bandage. This bandage should not be placed in an attempt to stabilize or immobilize the fracture at this time; it is simply to protect the open wounds and exposed bone from further contamination during initial patient resuscitation.

Specific management recommendations for open fractures. MWDs with open fractures generally will require surgical correction of the fracture once evacuated to veterinary facilities. The overriding aims are to prevent bacterial infection and promote normal healing.

- Culture open fracture sites as soon as possible after presentation and before antibiotic use if possible.
- Administer antibiotics as per Table 20 in Chapter 14, focusing on use of intravenous antibiotics based on

(Continued on page 93)

likely contaminants. Never withhold antibiotic therapy in any patient with an open fracture.

- Address pain with appropriate analgesic therapy (See Chapter 16). Reassess pain every 4-6 hours.
- Manage soft tissue injuries over the fracture site appropriately, as proper management of the wound postures the patient for successful outcome. See Chapter 14 for wound management recommendations.
- After appropriate wound care, apply a sterile moisture-retentive bandage over open fractures, as it is important to keep soft tissues and bone moist for optimal healing. Change bandages at least once daily, based on degree of strike-through, soiling, or loosening.

TABLE 18. MANAGEMENT OF LONG BONE FRACTURES IN MWDS[1,2]

1. Address life-threatening problems first!

During resuscitation, protect any open fractures.

- Do not attempt to reduce bones protruding at the fracture site.
- Remove any large gross contaminants from the wound, such as leaves, rocks, or stick fragments, but do not clip hair or cleanse the wound at this point.
- Cover the fracture and wound with sterile non-adherent dressing and apply a light protective bandage.

2. LOWER LIMB FRACTURES -- After resuscitation, immobilize fractures or joint abnormalities involving the limbs below the elbow or knee, prevent bacterial infection, provide analgesia, and promote normal healing until definitive surgical repair.

- Culture any open fracture sites as soon as possible, and before antibiotic use if possible.
- Administer antibiotics as directed in Chapter 14 for open fractures.
- Manage any open wounds over the fracture site as per Chapter 14.
- Provide analgesia as directed in Chapter 16. Reassess pain every 4-6 hours.
- Apply splints or heavy bandages to immobilize the fracture site, ensuring the joints above and below the fracture site are immobilized.

3. UPPER LIMB FRACTURES – After resuscitation, minimize further injury to fractures of the limbs above the elbow or knee.

- Culture any open fracture sites as soon as possible, and before antibiotic use if possible.
- Administer antibiotics as directed in Chapter 14 for open fractures.
- Manage any open wounds over the fracture site as per Chapter 14.
- Provide analgesia as directed in Chapter 16. Reassess pain every 4-6 hours.
- Unless experienced in external coaptation, DO NOT apply splints or heavy bandages, as these are poorly tolerated by MWDs and will increase the risk of displacement and further injury to the neurovascular bundle.
- Confine the MWD to a kennel or small space; limit walks; and support as needed when walked.

4. Monitor MWDs with fractures.

- Ensure a device is used to prevent self-trauma (See Chapter 2).
- Assess pain frequently and ensure adequate analgesia.
- Change splints or bandages daily (open fractures, wounds, soiled or wet) or every other day (clean and dry splints or bandages that do not cover open fractures or wounds).

- Apply splints and bandages as described previously for open fractures of the radius/ulna or tibia, or lower aspects of the limbs. Confine MWDs with any fracture, but especially with upper limb fractures that cannot be immobilized.

Definitive Long Bone Fracture Repair

Definitive repair should be delayed until the patient can safely undergo anesthesia and surgery performed by veterinary personnel best equipped to manage MWD's post-operatively. There is no role for HCPs to attempt definitive repair of long bone fractures in MWDs. Standard practice human fracture management is to span the fracture with external fixation to stabilize during transport, with definitive repair at a later date. Spanning the fracture is not considered definitive repair, but is not appropriate for MWDs as they will be ambulatory and break the construct. Thus, temporary external skeletal fixation is not indicated in MWD long bone fractures. The goals for HCP care of MWDs are initial management, stabilization, and evacuation to veterinary medical personnel for definitive care.

Pelvic Fractures

Pelvic fractures in MWDs in deployed settings will most likely be due to crush or blast injury (See Chapter 12). Evaluate the pelvis for external evidence of trauma or deformity.

The major joints involving the pelvis are the coxofemoral (hip) and sacroiliac (lower back) joints. Fractures or dislocations of these bones and joints are fairly common. A tip off for joint dislocation is asymmetry. Carefully palpate the hip joints and lower back for swelling, pain, or deformity that suggests joint injury. Move the limbs carefully through their range of motion while palpating the hip area and lower back to evaluate hip luxation.

Trauma to adjacent structures such as the rectum, descending colon, urinary bladder, urethra, and reproductive organs is a concern. Evaluate the inguinal area and external genitalia for evidence of trauma or herniation. Fractures of the pelvic floor commonly cause asymmetry, swelling, and bruising in the inguinal region. Hidden internal injury due to fractures (e.g., urethra, urinary bladder, prostate, vagina) is difficult to detect. Assess neurologic input to the anus by pinching the skin around the anus with hemostatic forceps—the expected response is sudden tightening of the anal sphincter.

Examine external genitalia for trauma. Carefully perform a digital rectal exam with a well-lubricated finger to assess for bleeding and injury to the urogenital structures in the pelvic canal, and to palpate for pelvic fractures.

Manage pelvic fractures by confining the MWD to its kennel or to a small space, limiting movement to short, frequent, handler-controlled leash walks using a towel or other material passed beneath the abdomen to provide support when walking, and adequate analgesia (See Chapter 16).

CHAPTER 14

Wound Management

Open Wounds and Necrotic Tissue

MWDs with wounds are frequently presented for care. Wounds commonly result from ballistic injuries, bites, motor vehicle trauma, or other trauma. In most cases, traumatic wounds can be classified as contaminated or dirty/infected wounds; the difference is based on how long the wound existed before presentation. Contaminated wounds generally are considered those less than 6 hours old, and dirty/infected wounds are considered those greater than 6 hours old and generally with obvious exudates or infection. Wounds are often noted in conjunction with potentially life-threatening injuries; thus, in all MWDs presenting with wounds, a detailed systematic triage examination and a careful search for – and management of – more severe concurrent injuries must take precedent over management of wounds. In all instances, wound care follows resuscitation and stabilization of the patient.

Considerations in Wound Management

The primary goal in wound management is to create a healthy wound bed, one that has adequate blood supply to support repair, and without contamination or necrotic tissue that will impede healing and increase the risk of infection. Unless simple and small, many wounds will require frequent evaluation, generally at least once daily, based on location, extent, severity, and other factors. Many wounds will need to be managed as open wounds (although protected by bandages until smaller) before definitive surgical repair. The steps in daily wound evaluation are to assess the response to or need for antibiotics, debride dying or necrotic tissues and lavage the wound, assess for surgical closure, and protect the wound.

Initial Wound Management Recommendations

Provide effective analgesia or anesthesia based on wound severity, location, and other factors (See Chapter 16 and Table 19).[1-6]

1. Apply sterile water-soluble lubricant liberally to the wound bed and then clip the hair generously around the wound. Gently cleanse the skin around the wound, but not the wound bed, with surgical scrub. Gently lavage the lubricant and gross contaminants from the wound using sterile saline or lactated Ringer's solution (LRS); do not use tap water except in very grossly contaminated wounds with large amounts of debris, in which case it may be more expedient to flush the wound with warm water under gentle pressure initially. The goal of initial lavage is to remove gross contaminants and reduce the bacterial burden.

2. Debride grossly necrotic tissues and non-viable tissue carefully using aseptic technique and sharp dissection. Do not mass ligate tissues or use cautery excessively, as this usually leads to necrosis of these tissues

and serves as a bed for infection. Use caution not to damage, transect, or ligate major blood vessels (unless actively hemorrhaging) or nerves, as these are crucial to maintain effective blood flow and innervation distally.

3. Lavage of the wound is necessary to remove particulate debris and reduce bacterial contamination – remember the adage, ***"The solution to pollution is dilution."***

   - There are several devices acceptable and available for adjunctive wound irrigation. Simple bulb irrigation and gravity irrigation have been the preferred method of wound irrigation. The bulb and syringe method has been more widely accepted and is significantly less expensive. Large bore gravity-run tubing has been favored for quick irrigations. Pulsatile jet lavage irrigation using a battery powered system is another method of adjunctive irrigation in the overall management of contaminated crushed wounds. It must be emphasized that all methods of wound irrigation, including pulsatile lavage, are adjuncts to sharp, surgical debridement and not a substitute for surgical debridement.

   - Normal saline, sterile water and potable tap water all have documented similar usefulness, efficacy and safety. Sterile isotonic solutions are readily available and remain the fluid of choice for irrigation. If unavailable, sterile water or potable tap water can be used.

   - Bacterial loads drop logarithmically with increasing volumes of 1, 3, 6, and 9 liters of irrigation. The current recommendations are as follows: 1-3 liters for small volume wounds, 4-8 liters for moderate wounds, and 9 or more liters for large wounds or wounds with evidence of heavy contamination.[3]

4. Generally, contaminated and dirty/infected wounds should not be sutured until healthy granulation tissue is established, which generally occurs in 3-5 days. This is especially true for bite wounds.

Bandaging Recommendations

- In nearly all cases, open wounds should be bandaged to protect the wound from contamination and support the wound while it heals. In most cases, mechanical debridement is desired (i.e., in most wounds after initial management has been performed, with varying degrees of contamination or infection), so use an adherent dressing. Once a healthy granulation bed has formed, convert to a non-adherent dressing.

- The most common adherent dressing is a wet-to-dry bandage, consisting of sterile gauze sponges that are saturated with sterile saline, gently wrung to eliminate excessive moisture, and the applied directly to the wound. Over the wet dressing, several dry gauze sponges are applied. In large wounds, laparotomy sponges may be optimal to cover more wound bed.

- The most common non-adherent dressing is a semi-occlusive cotton pad (e.g., Telfa®) that retains moisture against the wound bed and 'wicks' exudate from the surface of the wound.

- Use topical silver sulfadiazine ointment or triple-antibiotic ointment on most wounds.

- Apply a secondary layer over the primary layer. Most commonly, rolled cast padding or roll cotton is used to provide support. Splints can be included in the secondary layer, if used.

- Apply a tertiary layer, typically consisting of non-adherent conforming bandage, adhesive bandage, or both. This layer holds the dressing and secondary layer in place, provides additional support, and provides more durable protection of the underlying layers. In most cases, the tertiary layer is applied just tight enough to hold the bandage in place, and without compression.
- Change bandages at least once daily. More frequent bandage changes may be necessary if the wound has a heavy discharge or the bandage becomes soiled or partially removed by the MWD. Once wound discharge is reduced and a healthy granulation bed has formed, bandage changes become less frequent, generally every 2-3 days.
- Any MWD with a bandage applied must be prevented from chewing at the bandage. A plastic bucket with the bottom cut out can be used to prevent self-trauma can be attached to the dog's collar as an effective prevention practice (See Figure 21 and Figure 22).
- Negative pressure wound therapy (NPWT; e.g., WoundVac®) has proven a viable treatment modality for wounds in dogs, but requires proper training to apply properly to dogs and frequently heavy sedation of the MWD to prevent disruption of the dressing. HCPs with experience with NPWT are encouraged to consult with supporting veterinary personnel if this treatment modality is considered necessary before the MWD is evacuated to a veterinary facility. In most cases, application of NPWT can be delayed until the MWD is evacuated to a veterinary facility for long-term care.
- A "tie-over" bandage should be used in locations that are difficult to place a bandage, such as the inguinal area, dorsum, hip, and flank. Routine bandages placed in these areas typically slip off, and fail to protect the wound. A tie-over bandage consists of the same layers of bandage material, whether adherent or non-adherent, placed within and over the wound in a packing fashion. Multiple suture loops are placed around the periphery of the wound in the skin, evenly spaced around the wound, using large (2-0 or larger) monofilament suture material. The wound is then covered with a portion of impermeable drape or similar material. The bandage is then secured using umbilical tape or similar material laced through the suture loops (see Figure 44). Ties of surgical masks are a good substitute if umbilical tape is not available. The ties should be sufficiently tight to hold the bandage in place, with mild tension on the suture loops. The covering layer should be snug over the top of the underlying layers. A tie-over bandage will not have a compression layer.

Figure 44. Tie-Over Bandage.

Antibiotic Use with Open or Necrotic Wounds

Systemic antibiotics are indicated for any MWD with moderate or severe wounds. Wound cultures are indicated at admission if the patient presents with a dirty/infected wound, if obvious infection develops during any phase of wound management, if the wound fails to heal normally, or if systemic signs of infection develop. Continue antibiotics for a minimum of 7 days (See Table 20).

TABLE 19. MANAGEMENT OF OPEN OR NECROTIC WOUNDS IN MWDS[1-6]

1. Manage potential local and systemic infection.

a. Collect samples for microbial culture and sensitivity testing, preferably before antibiotic therapy is started. Transfer samples to supporting veterinary personnel for submission.

b. Initiate antibiotic therapy within the first 6 hours of the wound's development, or as soon as possible thereafter (See Table 20 for antibiotic selection and dosing).

c. Culture the wound if obvious infection develops during any phase of wound management, if the wound fails to heal normally, or if systemic signs of infection develop.

2. Provide initial wound management.

a. Provide effective analgesia or anesthesia based on wound severity, location, and other factors (See Chapter 16).

b. Apply sterile water-soluble lubricant to the wound bed and then clip the hair generously around the wound.

c. Gently cleanse the skin around the wound, but not the wound bed, with surgical scrub.

d. Gently lavage the lubricant and gross contaminants from the wound using sterile saline or lactated Ringer's solution (LRS).

e. Debride grossly necrotic tissues and non-viable tissue carefully using aseptic technique and sharp dissection.
   1) Do not mass ligate tissues or use cautery excessively.
   2) Do not damage, transect, or ligate major blood vessels (unless actively hemorrhaging) or nerves, as these are crucial to maintain effective blood flow and innervation distally.

f. Lavage the wound to remove particulate debris and reduce bacterial contamination.
   1) Thoroughly lavage the wound bed.
   2) Lavage under pressure.
   3) Sterile isotonic solutions are the fluid of choice.

g. Bandage the wound.
   1) Apply a primary layer to provide mechanical debridement initially, using a wet-to-dry bandage, consisting of sterile gauze sponges saturated with sterile saline, gently wrung to eliminate excessive moisture, and applied directly to the wound.
   2) Apply several dry gauze sponges over the primary layer.
   3) Apply a secondary layer over the primary layer, using cast padding or roll cotton +/- splints to provide support.
   4) Apply a tertiary layer of non-adherent conforming bandage, adhesive bandage, or both, using light compression.
   5) Apply a "tie-over" bandage in areas that are not amenable to routine bandaging.

3. Provide daily wound care until evacuation, using appropriate analgesia, sedation, or anesthesia. Change bandages at least once daily, but more frequently if heavy discharge is present or the bandage is soiled or partially removed by the patient. Lavage the wound as above at every bandage change. Debride the wound as above at every bandage change. Apply a new bandage as above; however, change the primary layer to a non-adherent dressing once a healthy granulation bed is formed.

TABLE 20. ANTIBIOTIC SELECTION AND DOSING FOR MWDS			
Antibiotic	**Dose for MWD**	**Route**	**Frequency**
Amoxicillin	20 – 30 mg/kg	PO	q 12 h
Amoxicillin-Clavulanic Acid	13.75 mg/kg	PO	q 12 h
Ampicillin	20 – 30 mg/kg	IV	q 8 h
Ampicillin Sulbactam	20 – 30 mg/kg	IV	q 8 h
Cefazolin	20 -30 mg/kg	IV	q 8 h
Cefotaxime	22 mg/kg	IV	q 8 h
Ceftriaxone	25 mg/kg	IV	q 8-12 h
Cephalexin	30 mg/kg	PO	q 12 h
Ciprofloxacin	35 mg/kg	PO	q 24 h

Ocular Injuries

Ocular injuries in MWDs in deployed settings will likely include irritant conjunctivitis, corneal ulceration, eyelid lacerations, and penetrating foreign objects. Clinical signs of ocular and periocular injury include eyelid lacerations, swelling of the periorbital tissues or conjunctiva, exudate in the conjunctival sac or on the eyelids, blepharospasm, intense redness of the conjunctiva, epiphora, photophobia, and rubbing the eye. Penetrating foreign objects may be present.

Evaluations of Ocular Injuries

1. Sedate the MWD as needed to allow detailed but safe examination of the affected eye (See Chapter 16).
2. Flush the affected eye and adjacent tissues with copious amounts of sterile saline or ophthalmic rinse.
3. Topically anesthetize the affected eye to facilitate examination, using 3-4 drops of topical ophthalmic anesthetic solution (e.g., proparacaine) on the cornea.
4. Remove exudate from the affected eye, if present, using saline-soaked cotton balls.
5. Examine the conjunctival area for foreign objects (e.g., particles, grass, plant seeds, thorns).
6. Stain the cornea of any affected eye using fluorescein stain to evaluate for ulceration.
7. Apply stain to the cornea, allow stain to dwell for at least 1 minute, and then rinse copiously with sterile saline or ophthalmic rinse.
8. Examine the eyes for symmetry, anisocoria, abnormal PLRs, or lens abnormalities.
9. While specific treatment of these problems is beyond the scope of practice for HCPs, the presence of these findings may suggest additional injury (e.g., TBI), that may need to be managed by the HCP.
10. Apply a bucket to the dog's collar to prevent self-trauma in ALL cases of ocular or periocular injuries in MWDs until the problem has resolved (See Figure 21 and Figure 22).

Treatment of Ocular Injuries

1. Irritant conjunctivitis

- Noted by varying degrees of conjunctival hyperemia, mild-to-moderate chemosis, and absence of other ocular signs.
- Flush eye and adjacent tissues with sterile saline/ophthalmic rinse 1-2 times daily.

- Apply bland ophthalmic antibiotic ointment (preferable) or solution (e.g., bacitracin-neomycin-polymyxin), q8h for 5 days.
- If corneal ulceration is present, DO NOT USE topical corticosteroids, as the risk of worsening the ulcer is high.
- If corneal ulceration is not present, the ophthalmic ointment can include topical corticosteroids. The eye MUST BE examined daily and fluorescein stain applied daily to ensure ulceration has not developed. Discontinue use of topical ophthalmic corticosteroids if any evidence of corneal ulceration is noted.

2. Corneal ulceration

- Noted by varying degrees of conjunctival hyperemia, mild-to-moderate chemosis, and presence of fluorescein dye uptake on the affected cornea.
- Flush eye and adjacent tissues with sterile saline/ophthalmic rinse 1-2 times daily.
- Apply bland ophthalmic antibiotic ointment (preferable) or solution (e.g., bacitracin-neomycin-polymyxin), q8h for 5 days.
- DO NOT USE topical corticosteroids, as the risk of worsening the ulcer is high.

3. Penetrating or embedded foreign object.

- Noted by the presence of a foreign object on the surface of or embedded in or through the cornea, with varying degrees of corneal edema. If the injury is chronic, neovascularization of the cornea may be present.
- Flush the eye and adjacent tissues with copious amounts of sterile saline/ophthalmic rinse 1-2 times daily.
- If the object is on the surface of or embedded on the outer cornea, attempt cautious removal after topically anesthetizing the eye.
    - If the object is removed, apply topical bland ophthalmic antibiotic ointment (preferable) or solution (e.g., bacitracin-neomycin-polymyxin) to the affected eye, q8h for 5 days.
    - DO NOT USE topical corticosteroids, as the risk of worsening the injury is high.
- If the object cannot be removed from the surface of the cornea, or appears to penetrate the cornea or globe, do not attempt to remove the object.
    - Apply topical bland ophthalmic antibiotic ointment (preferable) or solution (e.g., bacitracin-neomycin-polymyxin) to the affected eye, q8h for 5 days.

- DO NOT USE topical corticosteroids, as the risk of worsening the injury is high.
- Do not attempt to bandage the eye/head. The anatomy of the canine head is such that attempts to bandage the eye generally are unsuccessful and bandages tend to worsen ocular injuries. Although it is counterintuitive, leave the affected eye unbandaged.
- Evacuate the MWD to a veterinary facility on an URGENT basis once feasible.

4. Eyelid and peri-orbital lacerations.

- Noted by the presence of lacerations or abrasions affecting the peri-orbital tissues.
- Deeply sedate or anesthetize the MWD (See Chapter 16).
- Close subcutaneous tissues in 1 or 2 layers, using absorbable 3-0 or 4-0 monofilament simple interrupted sutures.
- Close the skin using nonabsorbable 3-0 nylon.
- Apply topical bland ophthalmic antibiotic ointment (preferable) or solution (e.g., bacitracin-neomycin-polymyxin) to the affected eye, q8h for 5 days.

Ocular Injury References

Analgesia and Anesthesia

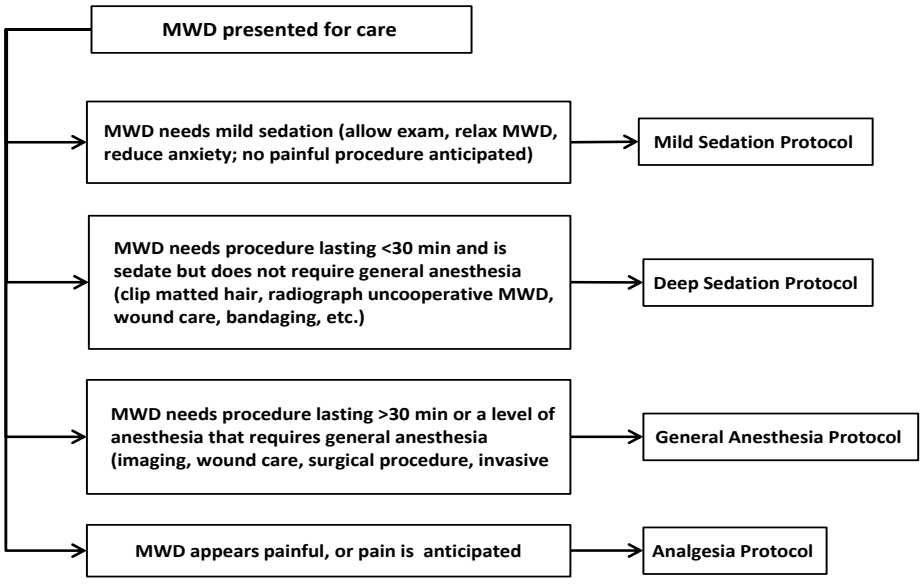
This chapter provides succinct, quick reference protocols for analgesia and anesthesia of emergently ill or injured MWDs, using simple combinations of drugs readily available to most HCPs.[1] A decision-making algorithm is provided below (Figure 45) to determine which analgesia or anesthesia protocol is recommended, based on specific need. Before any use of analgesia or anesthesia, a full physical exam must be performed.

MWDs can be fractious and difficult to manage, and often require heavy sedation for relatively simple procedures. Tailored protocols are provided, based on the level of sedation or anesthesia required – mild or deep sedation, or general anesthesia.[1]

Prehospital Analgesia

MWD handlers or combat medics may have given morphine, fentanyl, or ketamine before arrival, so inquire about drug use before transport, which may affect assessment of the patient's mentation and analgesia.

Figure 45. Decision-making Algorithm for Analgesia or Anesthesia.



Protocol Guidance

All drug combinations use the intramuscular (IM) route for ease and safety. If used within 5 minutes, all drugs can be combined in the same syringe to simplify administration. ***Wait at least 20 minutes after administration before attempting any procedure, to allow maximal drug effect***. Ideally, an IV catheter should be placed once feasible (See Chapter 2).

Drug Dosing in Dogs

Dosages for many analgesics in dogs are significantly higher than for people. Trust the doses provided in this chapter, and dose as directed to prevent inadequate analgesia or sedation and 'wind up' pain.

Gastrointestinal Side Effects of Opioids

Protocols include opioids, which in dogs typically causes emesis, often within 5 minutes of administration. Use caution and have the handler prepared to remove the muzzle to minimize aspiration risk.

Mild Sedation Protocol

- Use to relax MWDs for examination, handling, or short minor procedures that will not cause pain. Use to reduce anxiety.
- **Protocol:** MIDAZOLAM 0.3 mg/kg IM and HYDROMORPHONE 0.2 mg/kg IM.
- **Expectations:** The MWD will be calm, but reactive and noise sensitive.

Deep Sedation Protocol

- Use for procedures that can be completed in <30 minutes and do not require general anesthesia, such as clipping of hair, wound cleansing, minor wound debridement, splinting of lower limb fractures, bandage application or removal, ear cleaning, or radiography. First-line protocol for fractious MWDs.
- **Protocol:** MIDAZOLAM 0.3 mg/kg IM and KETAMINE 5 mg/kg IM and HYDROMORPHONE 0.1 mg/kg IM.
- If deeper sedation or light anesthesia is necessary, or to allow general anesthesia induction, use PROPOFOL in 1 mg/kg boluses IV as needed.
- **Expectations:** The MWD will not be able to walk, cannot be intubated, can be aroused with stimulation, and maintains laryngeal and palpebral reflexes.

General Anesthesia Protocol

- Use to facilitate imaging, allow management of fractures, perform surgical procedures, and perform invasive diagnostic procedures.
- Preoxygenate for 5 minutes using oxygen mask.

- Premedicate using the Deep Sedation Protocol, and place an IV catheter.
- Induce using PROPOFOL 1 mg/kg IV boluses to effect.
- Intubate with an appropriate endotracheal tube. Most MWDs require a 9-11 mm ID endotracheal tube. Use a cuffed tube.
- Maintain anesthesia using ISOFLURANE 0.5-1.5% titrated to effect in 100% oxygen or SEVOFLURANE 2.0-2.5% titrated to effect in 100% oxygen or PROPOFOL CRI 100-300 mcg/kg/min.
- Manage pain with HYDROMORPHONE 0.1 mg/kg IV boluses, not to exceed 0.2 mg/kg per hour.
- Monitor appropriately, give IV fluids, and keep the MWD warm (See **Ancillary Support** in this chapter, and Table 21 on the next page).

Effective Analgesia Protocols for MWDs

Assessment of pain in dogs is difficult. Dogs are generally very stoic and often hide or fail to show outward signs of pain. HCPs should err on side of providing analgesia – if performed properly, it is safe and effective, and analgesia is critically important for safe handling and alleviation of pain.

- Note that all protocols have analgesia incorporated into them. Additional analgesia can be provided by the IV, IM, or PO route, as necessary.
- ***Scheduled administration of analgesics in the post-procedure period is preferred*** to as needed administration in dogs, because pain can be difficult to assess and to avert the 'roller coaster' effect of unmanaged pain.
- For intermittent IV or IM supplementary analgesia, use one of the following drugs:
  - HYDROMORPHONE 0.1-0.2 mg/kg q2-4h.
  - MORPHINE 0.2-0.5 mg/kg q4-6h
- For CRI supplementary analgesia, use one of the following drugs:
  - FENTANYL 2-10 mcg/kg/h.
  - MORPHINE 0.1-0.25 mg/kg/h.
  - HYDROMORPHONE 0.02-0.05 mg/kg/h.
- For PO supplementary analgesia, use TRAMADOL 5-10 mg/kg PO q8-12h for up to 5 days.

Caution: Do NOT use acetaminophen or ibuprofen in MWDs, as these drugs can cause liver toxicity. AVOID use of NSAIDs such as naproxen, meloxicam, and aspirin in emergently ill or injured MWDs.

Opioid Reversal

At appropriate doses, dogs appear less susceptible to opioid-induced respiratory depression and excessive sedation. However, opioid side effects can be reversed in the dog using NALOXONE 0.01-0.02 mg/kg slow IV to effect if needed. Note that this will reverse analgesia as well as sedation!

Ancillary Support

- Any MWD that is deeply sedated or under general anesthesia should be given IV crystalloid fluid therapy at 10 mL/kg/h to offset anesthesia-induced hypotension. Additional fluid volumes may be necessary based on the underlying problem (e.g., shock should be given IV fluids to targeted endpoints, as per Chapter 6, Figure 33).
- Active warming should be provided for any MWD that is deeply sedated or under general anesthesia. Use forced-air warmers, warm water circulating blankets, heat-retaining covers, and warming tables to target a body temperature of 100-101° F. Monitor temperature post-procedure until sustained >100^0 F.
- Basic and advanced monitoring of the MWD at a level considered appropriate for a human patient for the respective level of analgesia or anesthesia must be provided. Table 21 lists key monitoring parameters and goals for anesthetized MWDs, and common anesthesia machine settings.

TABLE 21. KEY MONITORING PARAMETERS & ANESTHESIA MACHINE SETTINGS

Parameter	Normal Values	Notes
Heart rate	60-100 bpm	See Chapter 2 for placement of ECG electrodes
Heart rhythm	Normal sinus	
Blood pressure	MAP >60 mmHg	Non-invasive technique
Pulse oximetry	97 ± 2%	See Chapter 2 for placement
Capnography	E_TCO_2: 35 – 45 mmHg	Up to 60 mmHg is permissible in a normoten-sive, spontaneously ventilating patient
Temperature	99 - 102.5 ^{0} F	Continuous recording probes can be inserted into the esophagus or rectum
Fresh gas flow	1 – 2 L/min	
F_IO_2	0.3 – 1.0 %	
Inhalant agent	Isoflurane: 0.5 – 1.5% Sevoflurane: 1.0 – 3.0 %	
Ventilation modes	Spontaneous (preferred) Volume controlled: TV=10-20 mL/kg Pressure controlled: PIP=1-25 cmH_2O BPM = 6-12 PEEP: 0 – 5 cmH_2O

CHAPTER 17

Traumatic Brain Injury and Acute Spinal Cord Injury

Traumatic brain injury (TBI) and acute spinal cord injury (ASCI) are uncommon in MWDs. These injuries are often catastrophic, with poor long-term outcome. Caring for affected MWDs is daunting and can tax resources. However, some CNS injuries are recoverable, so efforts to evaluate MWDs with TBI and ASCI should be made to determine the severity of injury and potential for successful outcome. Anticipate these injuries in MWDs exposed to building collapses, blast, and ballistics injuries.

Acute Spinal Cord Injury

Assume ASCI is present in every MWD trauma patient until proven it is not present. Maintain a high index of suspicion! 40-50% of MWDs with ASCI have concurrent injury elsewhere that may be more life-threatening.[1] Focus on initial resuscitation and stabilization, but constantly consider potential neurological injuries. Excessive movement can cause a partial injury to become a permanent injury. Limit movement during the initial exam and treatment period to that which is absolutely necessary until a detailed neurological exam is performed.

Clinical Signs Suggesting ASCI

Clinical findings of bruising over any part of the spine; spinal instability, misalignment, crepitus or pain along the spine; presence of head injury or altered mentation or level of consciousness; or major trauma to other body systems are early tips that ASCI may be present.

Specific neurological signs that strongly suggest ASCI include loss of conscious proprioception, loss of superficial and deep pain, and loss of function (paresis or paralysis).

Lesion Localization

It is ideal to localize the segment of the cord affected. Determine if upper motor neuron (UMN) or lower motor neuron (LMN) signs are present.

- **UMN signs** are characterized by increased motor tone causing normal or exaggerated limb reflexes, normal to increased muscle tone, and decreased proprioception and decreased superficial and deep pain sensation in areas caudal to the lesion.
- **LMN signs** are characterized by flaccid or weak motor tone causing depressed limb reflexes and decreased muscle tone in areas caudal to the lesion.

With both UMN and LMN involvement, paresis or paralysis are possible.

- C1-C5 – UMN signs to all 4 limbs, possibly abnormal respiration (shallow or absent).
- C6-T2 – UMN signs to the hind limbs and LMN signs to the forelimbs.
- T3-L3 – UMN signs to the hind limbs with normal forelimbs.
- L4-S2 – LMN signs to the hind limbs with normal forelimbs.

Diagnostic Imaging

Radiographs, CT, or MRI are often necessary for definitive diagnosis in patients with fractures or dislocations to determine the site of injury. If these imaging modalities are available and the MWD can be managed without worsening possible injury, attempt imaging (See Chapter 20). Heavy sedation or anesthesia will be necessary (See Chapter 16).

General Management Considerations for Patients with ASCI

Goals are to reduce neurological deficit and prevent further loss of neurological function (See Figure 46).

- Follow guidance in this CPG for management of shock, hypotension, hypovolemia, hemorrhage control, and respiratory dysfunction. Be prepared to intubate patients that are not breathing or have depressed ventilation. Careful intubation using manual in-line stabilization (MILS) is essential to minimize further injury.
- If signs suggest ASCI are present and the MWD is NOT ambulatory, immobilize the MWD using a backboard (plywood sheet, plastic board, EMS backboard, etc.) to which the animal is taped, and sedate with or without analgesia as often as necessary to prevent unwanted patient movement due to anxiety and pain.
- If signs suggest ASCI is present and the MWD IS ambulatory or adequate immobilization is not possible (due to lack of sedative/analgesia or support devices or patient temperament), confine the MWD to a small area or kennel and prevent excessive movement until evacuated.
- Do NOT use nonsteroidal anti-inflammatory drugs (NSAIDs).
- Do NOT give corticosteroids to MWDs with ASCI, UNLESS the animal has no deep or superficial pain, is paralyzed, or the neurological condition deteriorates. If corticosteroids are given, use ONLY a SINGLE dose of methylprednisolone sodium succinate, IV, 30 mg/kg over 15 minutes.

Conservative Management of ASCI

Indications for conservative (non-surgical) treatment include patients that are ambulatory or paraparetic, and patients that have strong voluntary movement and peripheral pain sensation.

- Maintain enforced confinement, analgesia, and sedation as needed to minimize movement.
- Evacuate URGENTLY if feasible.

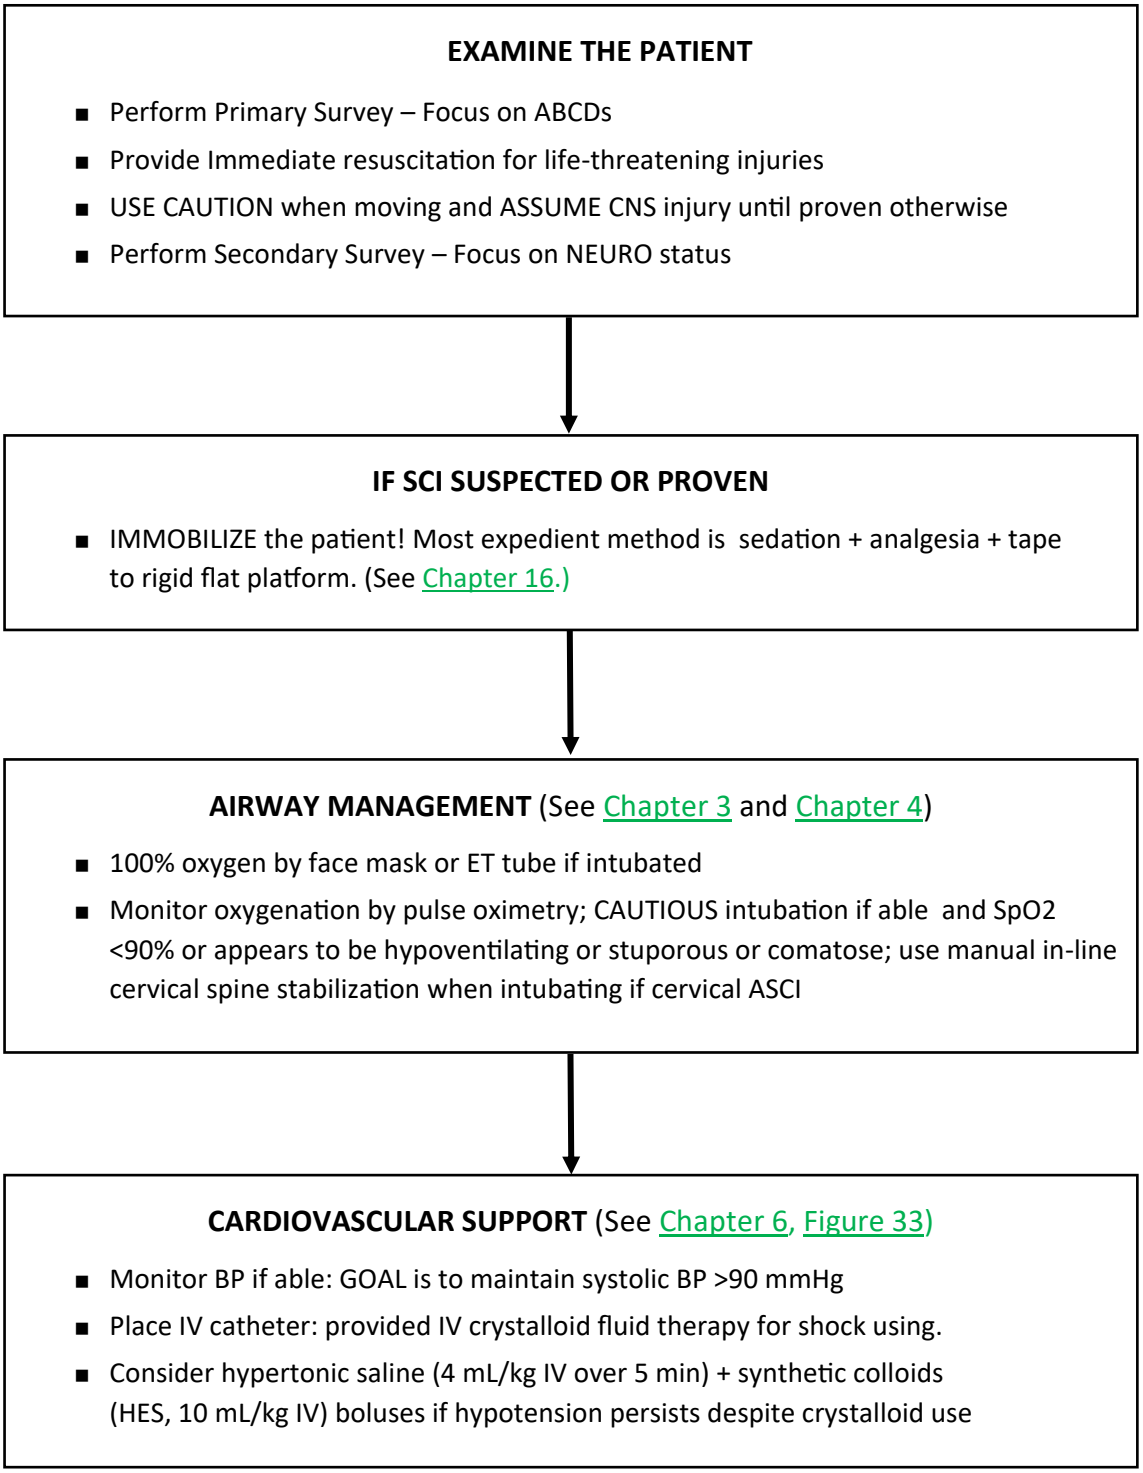
Surgical Management of ASCI

Early definitive surgical correction is indicated in non-ambulatory patients, patients with palpably unstable or displaced injuries, patients that deteriorate with conservative therapy, patients with peripheral pain sensation but no voluntary movements, and patients requiring decompressive surgery to correct displaced or fractured

spinal segments or bone fragments. Surgical management is likely not be feasible in a deployed setting.

- Definitive surgical repair of ASCI in MWDs should only be performed by qualified veterinary personnel.
- Evacuate as soon as feasible, or consider euthanasia (Chapter 21) if severe ASCI is present based on physical exam, diagnostic imaging results, lack of deep or superficial pain, or paralysis is present at any time.

Figure 46. Clinical Management Algorithm for Acute Spinal Cord Injury in MWDs.



EXAMINE THE PATIENT
Perform Primary Survey – Focus on ABCDs
Provide Immediate resuscitation for life-threatening injuries
USE CAUTION when moving and ASSUME CNS injury until proven otherwise
Perform Secondary Survey – Focus on NEURO status
IF SCI SUSPECTED OR PROVEN
IMMOBILIZE the patient! Most expedient method is sedation + analgesia + tape to rigid flat platform. (See Chapter 16.)
AIRWAY MANAGEMENT (See Chapter 3 and Chapter 4)
100% oxygen by face mask or ET tube if intubated
Monitor oxygenation by pulse oximetry; CAUTIOUS intubation if able and SpO2 <90% or appears to be hypoventilating or stuporous or comatose; use manual in-line cervical spine stabilization when intubating if cervical ASCI
CARDIOVASCULAR SUPPORT (See Chapter 6, Figure 33)
Monitor BP if able: GOAL is to maintain systolic BP >90 mmHg
Place IV catheter: provided IV crystalloid fluid therapy for shock using.
Consider hypertonic saline (4 mL/kg IV over 5 min) + synthetic colloids (HES, 10 mL/kg IV) boluses if hypotension persists despite crystalloid use

Traumatic Brain Injury

There is limited data on TBI in animals. Anticipate TBI in MWDs after trauma in 25-40% of cases.[2-6] TBI carries an extremely high mortality; assume a prehospital mortality of >40% in severe TBI cases. Management of MWDs is largely based on recommendations for treating people. Care by HCPs should be directed at efforts to mitigate secondary injury from hypotension, hyperthermia, hyper- and hypoglycemia, hypoxia, hyper-and hypocapnia, acid-base imbalances, electrolyte imbalances, SIRS, MODS, and ARDS. Thus, HCP care should be directed at maintenance of blood pressure, normoxemia, normal ventilation, and normal body temperature.

Clinical Signs Suggesting TBI

Brain injury should be suspected in any trauma patient with altered mentation (coma, stupor, depression, lethargy, inappropriate behavior or responses) or with physical evidence of head trauma (e.g., lacerations, abrasions, bruising, swelling, pain, bleeding from the nose or ears).

- Pay special attention to the patient's level of consciousness (LOC), overall pain response, pupillary light responses, cardiac and respiratory changes, motor activity and reflexes, and body temperature.
- The external ear canals and nasal openings should be examined for evidence of blood or CSF.
- The presence of lateralizing neurologic signs in a patient with brain injury suggests underlying intracranial hemorrhage; whereas patients with diffuse CNS deficits more probably have significant intracranial edema as a cause or contributor to their neurologic dysfunction.[2-5] These findings will affect treatment options.
- MWD posture on presentation may allow injury localization and estimation of prognosis. While these classic postures are not always noted, their presence can be used by first responders to identify severe TBI with poor-to-grave prognoses.
  - Patients with injury to the T2-L2 thoracic spine often display the Schiff-Sherrington syndrome (Figure 47, inset A), typically with normal mentation, forelimbs in extensor rigidity, and hind limbs that are flaccid. The prognosis for these patients is usually grave due to severe spinal cord trauma.
  - Patients with decerebellate rigidity (Figure 47, inset B) typically are obtunded or depressed, have

Figure 47. Characteristic Neurologic Postures on Presentation.

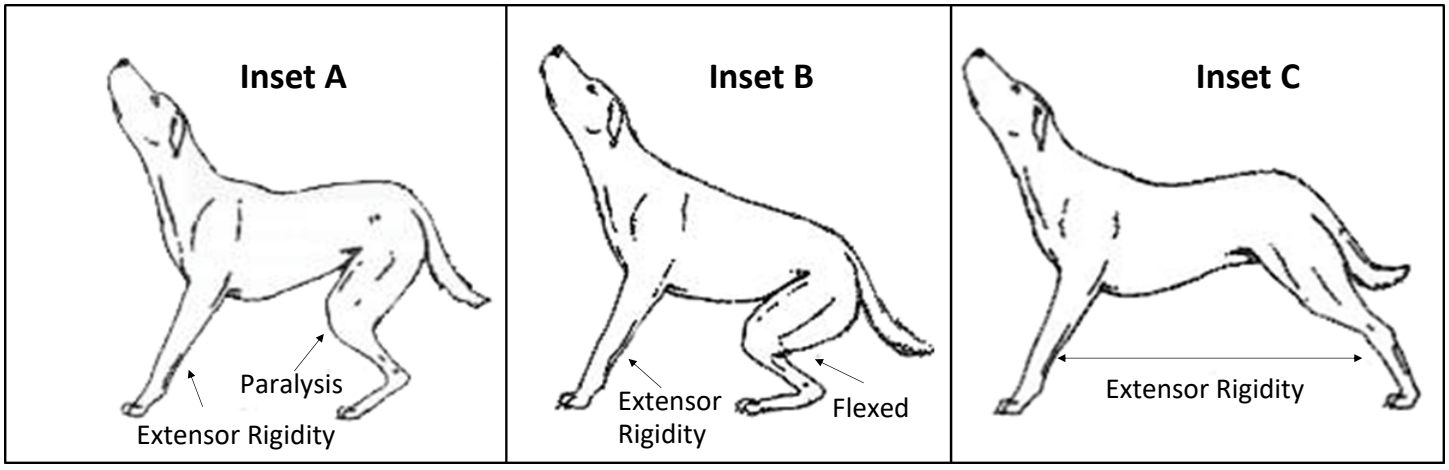


TABLE 22. MODIFIED VETERINARY GLASGOW COMA SCALE[7]	
Level of Consciousness	**Score**
Occasional periods of alertness and responsive to environment	6
Depression or delirium, capable of responding but response may be inappropriate	5
Stupor – semi comatose, responsive to visual stimuli	4
Stupor – semi comatose, responsive to auditory stimuli	3
Stupor – semi comatose, responsive only to repeated noxious stimuli	2
Comatose – unresponsive to repeated noxious stimuli	1
Motor Activity	
Normal gait, normal spinal reflexes	6
Hemiparesis, tetraparesis, or decerebrate activity	5
Recumbent, intermittent extensor rigidity	4
Recumbent, constant extensor rigidity	3
Recumbent, constant extensor rigidity with opisthotonus	2
Recumbent, hypotonia of muscles, depressed or absent spinal reflexes	1
Brainstem Reflexes	
Normal PLRs and oculocephalic reflexes	6
Slow PLRs, normal to reduced oculocephalic reflexes	5
Bilateral unresponsive miosis, normal to reduced oculocephalic reflexes	4
Pinpoint pupils, reduced to absent oculocephalic reflexes	3
Unilateral unresponsive mydriasis, reduced to absent oculocephalic reflexes	2
Bilateral unresponsive mydriasis, reduced to absent oculocephalic reflexes	1

opisthotonus, have fore limbs in extensor rigidity, and hind limbs in active flexion. These patients have a guarded prognosis due to severe injury to the cerebellum.

- Patients with decerebrate rigidity (Figure 47, inset C) typically are obtunded, have opisthotonus, and the fore limbs and hind limbs are in extensor rigidity. The prognosis for these patients is grave due to severe injury to the cerebrum.

Assessing Severity of TBI in MWDs

A modified veterinary Glasgow Coma Scale (Table 22 above) is validated for use in dogs.[7] Data is limited, however, correlating long-term outcome (i.e. prognostication) with initial or serial assessment of GCS in dogs.

- As with people, the lower the total GCS, the worse the TBI and the lower the expected survival with neurological function intact.
- Limited use in veterinary trauma patients has allowed development of suggested prognoses based on the MVGCS (See Table 23). HCPs should use this guidance when assessing severity of TBI and resource allocation.

TABLE 23. SUGGESTED PROGNOSES BASED ON MODIFIED VETERINARY GLASGOW COMA SCALE[7]	
MVGCS Score	**Suggested Prognosis**
3-8	Grave
9-14	Guarded
15-18	Good

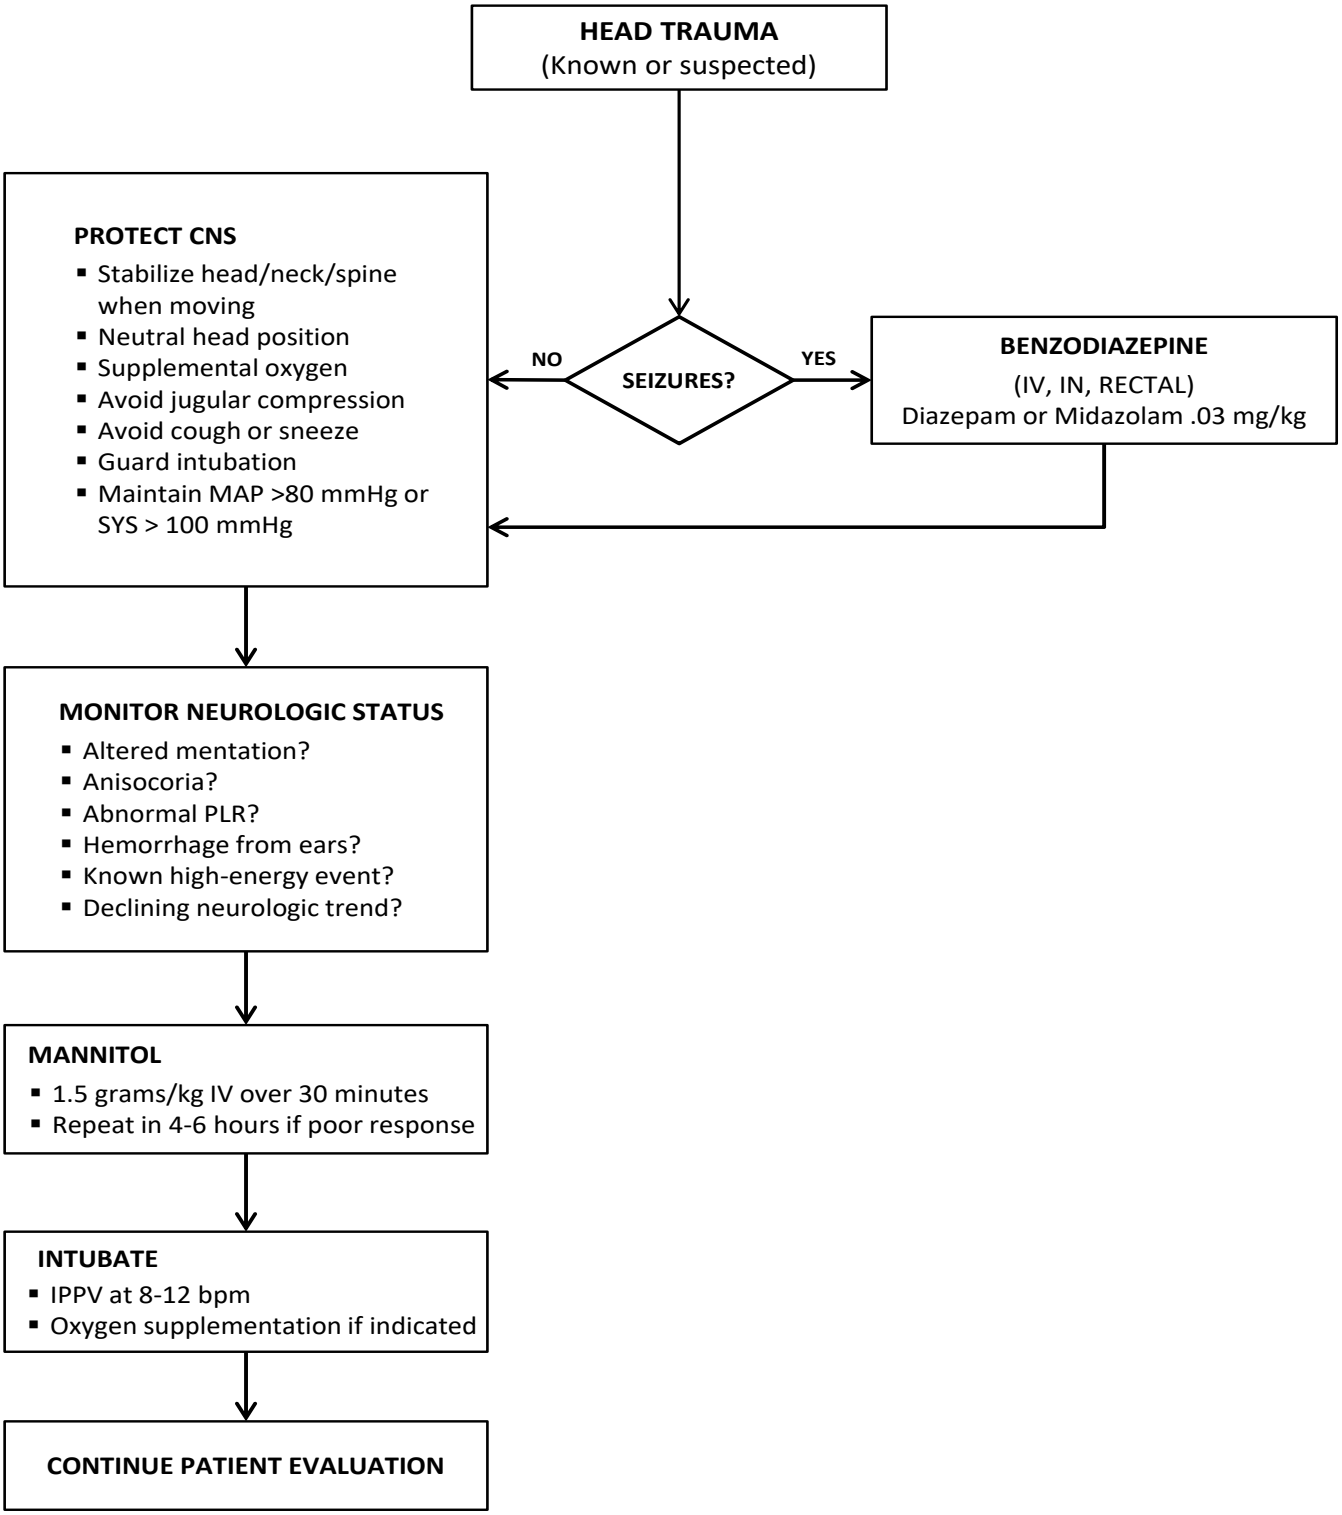
General Management Considerations for MWDs with TBI

It is critical to ensure adequate resuscitation and management of cardiovascular and respiratory problems, as hypotension, poor tissue perfusion, and hypoxia lead to progressive brain injury due to the adverse effects of secondary neurological injury due to ischemia, cerebral edema, reperfusion injury, and so forth. (See Figure 48 on the next page.)

- Follow guidance in this CPG for management of shock, hypotension, hypovolemia, hemorrhage control, and respiratory dysfunction.
- Be prepared to intubate patients that are not breathing or have depressed ventilation; careful intubation using manual in-line stabilization (MILS) is essential to minimize further injury.
- Focus care on preventing hypoxemia, maintaining cerebral perfusion pressure and systemic arterial pressure in the normal ranges, and preventing secondary ischemic cerebral injury.
  - Provide 100% oxygen by facemask. Monitor respiratory rate and effort. Be prepared to intubate and provide supplemental oxygen by ET tube. Maintain arterial carbon dioxide content in the normal range using assisted manual ventilation. Avoid hyperventilation!
  - Maintain normotension (MAP 70-80 mmHg or systolic BP >90 mmHg). Start IV crystalloid fluid therapy to correct shock and provide ongoing volume support (See Chapter 6, Figure 33). Measure blood pressure if possible; otherwise, guide fluid therapy based on presence or absence of distal pulses. Consider hypertonic saline (4 mL/kg IV over 5 min) or hyperoncotic fluid (HES, 10 mL/kg IV) boluses if hypotension persists despite crystalloid use.
  - Nurse with head elevated 30^0 with neutral neck position, avoid external jugular vein compression and catheters, avoid procedures that stimulate coughing or sneezing.
  - If evacuation will be prolonged and the patient is recumbent, rotate lateral recumbency and lubricate the eyes with ophthalmic ointment every 4 hours and maintain in a well-padded area.
  - If the MWD is conscious, restrict activity and movement (e.g., portable kennel), which may require sedation and analgesia (See Chapter 16).

(Continued on page 113)

Figure 48. Management Algorithm for TBI for MWDs.



- Give mannitol, 1.5 grams/kg, IV, over 30 min for MWDs with a MVGCS score of ≤ 8. Repeat this dose once more 4-6 hours after the first dose.
  Note that dogs are less likely to suffer subdural or intracranial hemorrhage; thus, mannitol should be used early in any MWD with moderate-to-severe TBI (MVGCS ≤ 8).
- ***Do NOT use corticosteroids to treat MWDs with TBI.***

Prognosis

HCPs must be realistic when treating MWDs with ASCI and TBI. While efforts and resources should be extended for MWDs with mild-to-moderate ASCI and TBI, HCPs should consider the likelihood of return to function. Consider euthanasia (See Chapter 21) for MWDs with catastrophic neurological injuries, or dogs with paralysis and that fail to respond to therapy or deteriorate despite care.

CHAPTER 18

Canine Post Traumatic Stress Disorder (C-PTSD)

Background

MWDs exposed to different types of intense external stimuli, such as explosions and gunfire, experience a syndrome that is similar to PTSD in people. While much remains unknown about this syndrome, most of the affected MWDs to date have been exposed to these stimuli in combat scenarios. Thus, it is reasonable that MWD handlers will seek medical guidance for acutely affected dogs from HCPs. It is essential to be aware of this syndrome and to effectively guide handlers in immediate care while working to evacuate affected dogs to veterinary facilities. Veterinary Corps Officers are the best resource for current diagnostic and therapeutic recommendations and will facilitate telemedicine consultation with experts at the DoD Military Working Dog Veterinary Service.

High Index of Suspicion

Maintain high index of suspicion based on antecedent events. HCPs should maintain a high index of suspicion for C-PTSD so as to identify potential MWDs for further evaluation. Inclusionary criteria in the immediate period include antecedent events, specifically any combination of the following:

- Concussive event (with or without physical injury)
- Exposure to a combat environment, and
- Prolonged or repeated deployment to combat zone.

Key Behavioral Signs Characteristic for C-PTSD

Specific behavioral signs are tip-offs that C-PTSD may be present. HCPs will need to rely on the MWD handler for information about these signs.

Signs include any combination of the following: escape or avoidance from work-related environments, increased or decreased reactivity to environmental or social stimuli, positive or negative changes in rapport with the handler, or interference with critical tasks (detection, controlled aggression, and obedience).
NOTE: Possible delayed onset or delayed reporting of clinical signs supporting C-PTSD is common.

Although MWD handlers will most likely seek guidance after acute onset of signs, HCPs should be aware some MWDs may not manifest obvious signs for some time, or handlers may not seek guidance until the syndrome is advanced. Additionally, some dogs will have been evaluated, with treatment initiated by veterinary personnel, with handlers seeking guidance some time later. Thus, other keys to C-PTSD for HCPs to be aware of are the continuance of behavioral signs for more than 30 days and failure to improve with time or treatment.

Rule Out Problems Mimicking C-PTSD

Some medical problems cause signs that mimic C-PTSD. HCPs should carefully evaluate dogs for exclusionary criteria, such as traumatic brain injury (See Chapter 17). A key tip-off that C-PTSD is likely not present is development of behavioral signs before the antecedent events noted previously. Veterinary personnel must rule out anecdotal reports and other appropriate behavioral diagnoses in order to validate a C-PTSD diagnosis.

Management Guidance for HCPS

Listen to the MWD handler! If a handler seeks guidance for his or her working dog due to abnormal behavior in the first 30 days after a traumatic event or combat action, HCPs should do the following:

1. Record the interaction and forward to supporting veterinary personnel (See Chapter 22).
2. Direct the handler immediately remove the dog from the situation, if not already done.
3. Upon approval from the supporting veterinary officer, provide an anxiolytic for dogs that have demonstrated a moderate-to-severe response, using one of the following agents, given PO (preferable), IV, or IM:
   - Clorazepate (TRANXENE®), 12.5 mg per dog PO q12h (moderate response)
   - Buspirone (BUSPAR®), 10-20 mg per dog PO q8-12h (moderate to severe response)
   - Alprazolam (XANAX®), 1-2 mg per dog PO q12h (moderate to severe response)
4. Direct the handler to provide support for the dog with social activity and play.
5. Direct the handler to provide work therapy by performing critical tasks in safe area, free from distress.
6. Recommend to the handler and the commander that the MWD not be used in the tactical environment until the dog has been evaluated by veterinary personnel.
7. Coordinate soonest evacuation to veterinary personnel for further evaluation and care, base on the tactical situation and resource availability. MWDs with C-PTSD should be classified as ROUTINE for evacuation planning purposes.

Long-term Management

There is no role for HCPs to attempt long-term or delayed management of presumed C-PTSD. Misdiagnosis and/or delay of appropriate treatment will equally jeopardize the affected MWD's proper therapy and potential of return to duty. Affected dogs should be evaluated under the supervision of Veterinary Corps Officers and through consultation with the DODMWDVS board-certified animal behaviorist. On-going research suggests a positive association with early diagnosis, +/- medication and focused desensitization/ counterconditioning performed by the MWD handler in the first 60-90 days of case management. Every attempt is made to return the MWD to duty and avoid unnecessary STRATEVAC/redeployment, which can result in security and readiness issues.

Training and Toxicoses in MWDs

MWDs are exposed to small quantities of select drugs and explosives, contained in specially-constructed containers called training aids. Training aid ingestion and toxicity are events unique to MWDs and working dogs employed by law enforcement agencies.

- Training aids that are of concern when ingested include nitrate-based explosives (TNT, water gel, dynamite, RDX , detonation cords, and C-4), smokeless powder, sodium and potassium chlorates, and drugs (marijuana, heroin, cocaine, and amphetamines).[1]
- Potential toxicity is a concern and it is plausible that HCPs will be presented with an MWD that has ingested a training aid and is or may become toxic.

Clinical Signs of Intoxication (by Agent)

MWD handlers will have critical knowledge of the agent to which an MWD was exposed, for training aid ingestion. Common agents used and associated clinical signs follow.

- **Nitrate/nitroglycerin-based explosives.** Ingestion may result in hypersalivation, severe CNS abnormalities (ataxia, incoordination, seizures, tremors), gastrointestinal irritation (nausea, vomiting), and methemoglobinemia (cyanosis, weakness, syncope, respiratory distress).
- **Smokeless powder explosive.** Ingestion may result in hypotension, CNS depression (ataxia, depressed mentation, incoordination), and methemoglobinemia (cyanosis, weakness, syncope, respiratory distress).
- **Potassium and sodium chlorate explosives.** Ingestion may result in methemoglobinemia (cyanosis, weakness, syncope, and respiratory distress), CNS abnormalities (ataxia, incoordination, and depressed mentation), gastrointestinal irritation (nausea, vomiting, abdominal cramping and pain, hemorrhagic diarrhea with melena or hematochezia), hematuria, hemoglobinuria, and renal and liver failure.
- **Marijuana/hashish.** Ingestion may result in altered mentation (disorientation), hallucinations (in the dog, typically manifested as vocalizing, useless scratching, hyperexcitability), nausea and vomiting, and respiratory distress.
- **Heroin.** Ingestion may result in bradycardia, respiratory distress, miosis, coma, and sudden death.
- **Cocaine and amphetamines.** Ingestion may result in restlessness, tachycardia, hyperexcitability, vocalization, excessive or unprovoked aggression, seizures, and mydriasis.

Treatment of Training Aid Toxicity[1]

If ingestion occurred ≤ 4 hours before presentation and the MWD is conscious and has normal CNS responses, induce vomiting.

- Apomorphine is the drug of choice to induce vomiting in the dog. MWD handlers are issued apomorphine in tablet form, which is generally available in 6 mg tablets. If available, place ¼ to ½ tablet into either conjunctival sac. Vomiting typically occurs in 5-10 minutes. Once vomiting has occurred, rinse residual apomorphine from the conjunctival sac.
- Apomorphine may be available in the HCP drug inventory as an injectable agent (10 mg/mL). If the injectable form is available, give 0.03-0.04 mg/kg IV. Emesis is typically evident within 5 minutes in most MWDs.
- An alternative is to give hydrogen peroxide orally if apomorphine is not successful or available. Give 1 mL per kilogram body weight of hydrogen peroxide 3% orally. Note that hydrogen peroxide is less successful than apomorphine.
- Do NOT use Syrup of Ipecac or salt, or try to induce vomiting manually. These methods are ineffective in the dog and risk intense gastrointestinal irritation in the dog, and bite wounds to the HCP.

If ingestion occurred >4 hours before presentation, or if the dog has abnormal mentation or is unconscious or seizuring, do not induce vomiting. In these cases, balance the benefit of gastric decontamination by orogastric lavage against the very real risk of aspiration pneumonia. If gastric lavage is elected, induce general anesthesia (See Chapter 16) and ensure a cuffed endotracheal tube is used. Lavage the stomach using repeated instillations of water at a dose of 10-20 mL/kg. Maintain the cuffed endotracheal tube until the MWD has regained a swallowing reflex.

The next critical step in management of any training aid toxicity is to administer activated charcoal.

- The dose for activated charcoal is 1.5 grams/kg PO. Most MWDs will ingest activated charcoal if the charcoal is mixed with canned food. If the MWD will not ingest the charcoal voluntarily, either have the handler syringe the slurry slowly orally or (if the MWD is anesthetized) give the slurry by orogastric tube. MWD handlers are issued Toxiban® with sorbitol and may have initiated therapy prior to presentation.
- Activated charcoal WITH sorbitol as a cathartic is preferred as the initial dose.
- Repeat activated charcoal once in 4-6 hours. This dose should not include sorbitol.

If seizures are present or develop, treat the MWD with a benzodiazepine.

- Give midazolam (0.3 mg/kg IV or IN) or give diazepam (0.3 mg/kg IV, IN, or per rectum).
- Repeat in 10-15 minutes if seizures persist or recur.

If methemoglobinemia is suspected or confirmed and deemed causing significant respiratory distress, treat with methylene blue (if available).

- The dose for methylene blue 1% in the dog is 1-2 mg/kg IV slow bolus.
- This dose can be repeated once or twice if respiratory distress persists.
- Methylene blue can cause severe Heinz body anemia in the dog, so monitor an HCT q6-8h if this drug is used.

Toxicoses in MWDs Reference

Bright PA. Military working dog training aids: toxicity and treatment. Air Force Occupational and Environmental Health Laboratory (AFSC), Human Systems Division, Brooks Air Force Base, TX, 1989;1-32.

Diagnostic Imaging

Diagnostic imaging of injured or ills dogs is frequently required for comprehensive patient evaluation. Veterinary facilities may not be equipped for imaging, or may be limited to plain radiography. Advanced imaging (e.g., MRI, CT) is often ideal, and veterinary facilities do not have these capabilities. This chapter provides guidance for HCPs with extensive training in the use of CT and MRI, when considering advanced imaging requirements, highlighting unique aspects when imaging dogs.

Computed Tomography vs Magnetic Resonance Imaging

CT is often superior to MRI and used for assessment of margins of osseous or mineralized structures compared to MRI. CT can assess soft tissue changes and differences fairly well by narrowing windows and levels under standard algorithms to see differences of attenuation of the x-rays, but cannot manipulate the soft tissues due to their molecular structure as MRI can in order to enhance or null their differences. Therefore, MRI is often far superior to CT at assessing for subtle changes within soft tissues due to the dramatic contrast enhancement. MRI is most often utilized in veterinary medicine and is the modality of choice when you are trying to assess soft tissue structures not easily accessed by an ultrasound probe or are looking for diseases that may not be appreciated via any other modality. MRI is used primarily for neurologic (brain and spine) imaging and joint imaging concerning cartilage, ligaments, and/or menisci. Keeping those general statements in mind, depending on the type of disease you are assessing for you may be able to appreciate the abnormalities on both modalities, so either study may be adequate for diagnosis. References are provided with specific imaging protocols for MWDs.[1-5]

Computed Tomography[3,4]

Sedation/Anesthesia

The patient must be either heavily sedated or anesthetized while the study is taking place. CT studies of the thorax and abdomen require general anesthesia and intubation of the patient, with closure of the pop-off valve on the anesthetic machine during image acquisition. Depending on how advanced the CT machine is and slice thicknesses needed, this may or may not be a problem for the patient, as the breath hold may have to last for several seconds. ***Always ensure anesthesia pop-off valves are not left closed, to avoid pneumothorax.***

Contrast Administration

Intravenous iodinated contrast may be used during a CT study in order to further enhance margins of soft tissue structures. If a CT is being conducted to assess an abnormal soft tissue mass or structure, intravenous iodinated contrast should be administered after acquisition of routine images prior to contrast administration for comparison purposes. This contrast administration allows for further characterization of the abnormal soft

tissue as only the vascular portions of the structure will enhance.

- The current standard for use of contrast during CT is non-ionic iodinated contrast media, with the two most common types being iohexol and iopamidol. Iohexol is most commonly used in MWDs. For a vial of iohexol at a concentration of 240mg/mL, the intravenous contrast dose is 400 mg/kg (rule of thumb is 1 mL of contrast agent per pound of body weight, not to exceed 60 mL).
- IV catheterization of the patient is required for contrast administration, and the contrast is a thick, sticky solution which needs to be bolused to the patient, so use 18 gauge catheters and syringe needles.
- After bolusing the contrast to the patient, only the study in the standard algorithm needs to be repeated.
- If the patient is dehydrated, the patient should be rehydrated prior to the CT study if possible or at least on IV fluids to correct the problem if unavoidable.
- Adverse side effects are rare with non-ionic contrast media in correctly hydrated patients.

CT Protocols

CT protocols will vary per region you are attempting to image, patient positioning, slice thickness, algorithms, and whether or not contrast will be used. Each of these factors is critical, but the most commonly overlooked factor is patient positioning. Ensure the region of the patient you are imaging is straight and symmetrically positioned on midline of the CT table, as subtle changes in obliquity may make structures appear abnormal when they are not. Use positional aids, sponges, or troughs if needed, and ensure that all metallic or other unnecessary objects are removed. Place the patient either head-first or hindlimb-first into the gantry, depending on which will be closest to the region for imaging. The following are recommended protocols for different body regions based on common problems seen in MWDs.

CT Skull

Patient positioning should be in ventral recumbency, with the hard palate parallel to the CT table. Studies should extend from the tip of the nose to the 2nd to 3rd cervical vertebra. Bone, standard, and bone algorithms with slice thicknesses of 2.5 mm, 1.25 mm, and 0.625 (if available) should be performed, respectively. Sagittal and dorsal reconstructions should be made as needed.

CT Nasal

Patient positioning should be in ventral recumbency, with the hard palate parallel to the CT table. Studies should extend from the tip of the nose to the larynx. A bone algorithm with slice thicknesses of 2.5 mm and 0.625 mm (or equivalent) and a standard algorithm with slice thickness of 1.25 mm should be performed. Intravenous contrast should be administered, and the standard algorithm with 1.25 mm thick slices repeated. Dorsal reconstructions are required. Sagittal reconstructions should be made as needed.

CT Brain

Patient positioning should be in ventral recumbency, with the hard palate parallel to the CT table. Studies

should extend from mid-muzzle to the 2nd to 3rd cervical vertebra. Bone, standard, and brain algorithms with slice thicknesses of 2.5 mm, 1.25 mm, and 1.25 mm should be performed, respectively. IV contrast should be administered and brain and standard algorithms repeated. Sagittal and dorsal reconstructions of the standard algorithms are required.

CT Tympanic Bullae

Patient positioning should be in ventral recumbency, with the hard palate parallel to the CT table. Studies should extend from the orbits to the 2nd or 3rd cervical vertebra. Bone and standard algorithms with slice thicknesses of 0.625 - 1.25 mm and 1.25 mm should be performed, respectively. Sagittal and dorsal reconstructions should be made as needed.

CT Spine

Patient should be positioned in dorsal recumbency, with the hind limbs maximally extended caudally (like for a hip-extended VD pelvic view in radiography). Study should extend through necessary vertebral regions based on pain and/or neurolocalization. More specifically for the hind limbs, if UMN signs are present, extend from T8-T9 through sacrum, and if LMN signs present, from T12-T13 through sacrum. CT slices should be acquired perpendicular to vertebral canal (may require gantry rotation). A bone algorithm with 2.5 mm and 1.25 mm slice thicknesses and a standard algorithm with 1.25 mm slice thickness should be performed. For suspect lumbosacral disease, the bone algorithm of 1.25 mm slice thickness should be replaced with 0.625 mm (or equivalent) slice thickness to better visualize the neuroforamina at the lumbosacral junction. Sagittal and dorsal reconstructions of bone and standard algorithms are required.

CT Thorax

Anesthesia and breath holds are required. Patient should be positioned in ventral recumbency. Study should extend from thoracic inlet through caudal aspect of liver (ensure extent of all lungs imaged). Bone, standard, and lung algorithms should be performed with slice thicknesses at 5.0 mm, 2.5 mm, and 1.25-2.5 mm, respectively. Sagittal and dorsal reconstructions of lung and standard algorithms are required.

CT Abdomen

Anesthesia and breath holds are required. Patient should be positioned in dorsal recumbency. Study should extend from caudal margin of cardiac silhouette through pelvic canal (or prostate if male). Bone and standard algorithms should be performed with slice thicknesses at 5.0 mm and 2.5 mm, respectively. Sagittal and dorsal reconstructions of bone and standard algorithms are required.

CT of Extremity or Joint

Patient positioning depends on whether imaging forelimbs or hindlimbs. For forelimbs, the patient is in ventral recumbency. The forelimbs should be extended cranially, resting the forearms and paws on the table with the elbows and shoulders bent at a normal resting position. If the hindlimbs are the focus of the study, the patient is usually placed in dorsal recumbency. The hindlimbs should be placed in maximal caudal extension, keeping both limbs symmetric and including both in the study for comparison purposes (use tape, sponges, or other

positional aids). CT slices should be acquired perpendicular to joint spaces, which may require gantry rotation if the joint is the focus of the study. Bone and standard algorithms should be performed along the affected region with slice thicknesses of 1.25 mm. If a joint the focus of the study, conducting an additional bone algorithm sequence with a slice thickness of 0.625 mm is required (if available). Sagittal and dorsal reconstructions of the affected limb only are required.

Magnetic Resonance Imaging[5]

Magnetic resonance imaging protocols used in veterinary medicine are more simplified compared to human medicine. However, current protocols are adequate in assessing for the majority of diseases of concern.

Anesthesia

Use either an MRI-safe anesthetic machine or constant rate IV anesthesia protocols (See Chapter 16). Patient monitoring presents challenges in the MR gantry due to increased noise, greater chance of hypothermia, and overall decreased patient accessibility.

MRI Technician Assistance

It is very important for the Veterinary Corps Officer to be present during image acquisition (if available) to help determine the beginning and end points (range) of the study in each plane, due to anatomic differences between humans and dogs (humans have five lumbar vertebrae compared to seven in dogs, for instance). Beginning and end points for the study should be based on neurolocalization.

MRI Contrast Administration

Paramagnetic contrast agents are commonly used during MRI. Contrast agent administration is always required when imaging the brain, and may be necessary for other exams dependent on the case. For example, if neoplasia or diskospondylitis of the spine is suspected, then administration of contrast during a spinal exam is warranted. All pre-contrast sequences must be performed prior to contrast bolus administration. The contrast agent most often used in MWDs for MRI is gadolinium-based, and the dose for IV bolus use in the dog is 0.1 mmol/kg (0.2mL/kg). As a quick rule of thumb, 1 mL per 10 pounds body weight is the appropriate dose.

MRI Protocols

MRI Brain

The patient should be positioned in ventral recumbency with the head encased within an effective coil (often head or cardiac types). Studies should extend from the most cranial limit of the orbits/eyes to the level of the 2nd or 3rd cervical vertebra. Slice thicknesses of 3-5 mm should be used; dependent on how many sequences you have time to perform. The following sequences in each respective plane should be performed:

- Axial/Transverse Plane. T1-weighted, T2-weighted, FLAIR, T1-weighted with contrast.
- Sagittal Plane. T1-weighted, T2-weighted, T1-weighted with contrast.
- Coronal/Dorsoventral Plane. T2-weighted, T1-weighted with contrast (T1-weighted pre-contrast also if time allows).

MRI Spine

The patient should be positioned in dorsal recumbency, and the coil within the table will likely be used. Study should extend through necessary vertebral regions based on pain and/or neurolocalization. More specifically for the hindlimbs, if UMN signs are present extend from the 8th or 9th thoracic vertebra through the sacrum, and if LMN signs are present, from the 12th or 13th thoracic vertebra through sacrum. Slice thicknesses of 2-4 mm should be used; dependent on how many sequences you have time to perform. The following sequences within each respective plane should be performed:

- Axial/Transverse Plane. T1-weighted, T2-weighted (T1-weighted with contrast if indicated).
- Sagittal Plane. T1-weighted, T2-weighted, STIR (T1-weighted with contrast if indicated).
- Coronal/Dorsoventral Plane. T2-weighted (T1-weighted pre and post- contrast administration if indicated).

MRI Stifle/Joint Imaging

The patient should be placed in lateral recumbency, with the affected limb up, with the stifle placed in neutral to moderate extension. Study should at least extend from distal femoral diaphysis to the proximal tibial diaphysis, distal to the tibial crest. A wrist coil is preferable, however if the joint/region to be imaged is too large, then cardiac or other similar coils may be used. Slice thicknesses of 2-3 mm should be used; dependent on how much time you have to complete the study. The following sequences within each respective plane should be performed:

- Axial/Transverse Plane. Proton Density (PD)-weighted (+/- fat sat).
- Sagittal Plane. PD-weighted (+/- fat sat), T1-weighted, T2-weighted (+/- fat sat).
- Coronal/Dorsoventral Plane. PD-weighted (+/- fat sat), T2-weighted (+/- fat sat).

CHAPTER 21

Euthanasia

MWDs may present with illnesses or injuries so severe that the only humane option is euthanasia. MWDs may be euthanized in the case of catastrophic wounding with poor prognosis for recovery and in order to relieve the MWD from undue suffering. Examples include catastrophic TBI, traumatic limb amputations, decompensatory refractory shock, and major abdominal evisceration injury, in addition to failure to respond to resuscitation, or rapid clinical deterioration with poor prognosis for recovery.

HCPs must recognize the need for euthanasia and perform euthanasia in a humane manner. Normally euthanasia requests must be authorized by either the first field grade officer in the MWD unit supervisory chain of command or a veterinarian. If possible, contact a veterinarian and receive verbal agreement to perform euthanasia. When in doubt, consider the best interest of the MWD, and perform euthanasia if felt necessary to relieve suffering.

All euthanasia procedures will be performed humanely and in accordance with the American Veterinary Medical Association Guidelines on Euthanasia.[1] Note that neuromuscular blocking agents are NOT an acceptable euthanasia agent, even when combined with other drugs.

In the deployed HCP setting, the following 3 options are recommended for canine euthanasia:

1. Commercial veterinary euthanasia solution. Several veterinary euthanasia products are available and include a barbituric acid derivative (usually sodium pentobarbital at ~400 mg/mL), often with local anesthetic agents or agents that metabolize to pentobarbital. Ideally, veterinary personnel will coordinate with adjacent or supporting HCP units to arrange access to these drugs in emergencies. Controlled substances management regulations apply.
    - These products should be given by the IV route.
    - The standard dose of these products is 1 mL per 10 pounds of body weight.
2. Barbiturate overdose. All barbituric acid derivatives used for anesthesia are acceptable for euthanasia when administered intravenously. There is a rapid onset of action, and loss of consciousness induced by barbiturates results in minimal or transient pain associated with venipuncture. Desirable barbiturates are those that are potent, long-acting, stable in solution, and inexpensive.
    - Sodium pentobarbital best fits these criteria and is most widely used.
    - The lethal pentobarbital dose for dogs is 40-60 mg/kg IV.

3. Potassium chloride (KCl). The use of a supersaturated solution of potassium chloride injected is an acceptable method to produce cardiac arrest and death. When using KCl, the MWD MUST BE anesthetized deeply before administration of KCl. It is unethical and unacceptable to use KCl in un-anesthetized animals.
    - Anesthetize the MWD (See Chapter 16).
    - Once anesthetized, rapid IV or IC administration of 1-2 mEq/kg KCl will cause cardiac arrest.
    - A typical dose for an average-sized MWD would be 30-40 mL of 2 mEq/mL KCl.
    - Bolus administration through IV catheter is the preferred route.

It is critical to ensure the death of the MWD after agents have been given for euthanasia. Ensure absence of a heart beat and pulse, absence of voluntary respirations, and absence of electrical activity on an ECG tracing (if available) for at least 5 minutes after presumed death. Agonal respiratory efforts are common and should cease before death is declared.

Whenever possible, a gross necropsy is recommended.

Collect blood and urine samples (one red top and one EDTA tube of blood and urine in a specimen cup or capped syringe) before euthanasia.

The MWD's body (ideally refrigerated, not frozen), all health records, and samples must be sent to the supporting veterinary facility for complete necropsy and final disposition paperwork.

If necropsy by veterinary personnel will be delayed, it is ideal to collect gross samples of major organs and tissues that are obviously abnormal or traumatized, and preserve with 10% buffered formalin. TB MED 283 (Veterinary Necropsy Protocol for Military Working Dogs) is an excellent reference.[2]

If possible and deemed appropriate by the senior HCP present, MWD handlers should be permitted to be present for euthanasia. The bond between handler and MWD cannot be overemphasized, and many handlers will want to be present. Note that the MWD handler as well as providers may require behavioral health care or grief counseling.

CHAPTER 22

Documentation—Medical Records

Canine Tactical Combat Casualty Care (cTCCC) Card

To document care at the point of injury, a canine Tactical Combat Casualty Care card (cTCCC card) has been approved for use, and is included in this chapter. This form should be used to document trauma or Disease, Non-Battle Injury at the point of injury anywhere an MWD is deployed, by the handler or provider who first provides care. Once care has been transferred to a medical facility, the form should be submitted to veterinary personnel for submission, or scanned and emailed by HCPs to dog.consult@us.af.mil.

The fillable electronic cTCCC care and instructions are available at:

https://jts.amedd.army.mil/assets/docs/forms/Canine_Tactical_Combat_Casualty_Card.pdf

https://jts.amedd.army.mil/assets/docs/forms/Instructions_Canine_Trauma_Combat_Casualty_Card.pdf

Canine Resuscitation Record Worksheet

To document medical care of MWDs by HCPs, all medical care provided in military medical facilities should be documented on the Canine Resuscitation Record. This new worksheet is included in this chapter. Input all relevant information to the best of your ability, recognizing the form has been revised for canine-specific information, and thus is significantly different from the DD Form 3019 used for human patients. Use a new worksheet each day the dog is an inpatient in the facility. Maintain the worksheets throughout the patient's care. Once care has been transferred to supporting veterinary personnel, either provide the worksheet to them, or scan and email it to dog.consult@us.af.mil.

The fillable electronic worksheet and instructions are available at:

https://jts.amedd.army.mil/assets/docs/forms/Canine_Resuscitation_Record.pdf

https://jts.amedd.army.mil/assets/docs/forms/Canine_Resuscitation_Record_Instructions.pdf

General Instructions for Canine Trauma Combat Casualty Care Card

PURPOSE: The Canine Tactical Combat Casualty Care (cTCCC) card is for documenting a trauma or disease non-battle injury (DNBI) at the point of injury anywhere a canine is deployed in support of DoD operations. The cTCCC card will be filled out by the handler or provider who attends to the canine's trauma or DNBI. After medical treatment and resuscitation care is provided, the cTCCC card can be handed off to the nearest veterinary treatment facility or supporting veterinary unit to be scanned, uploaded and emailed to dog.consult@us.af.mil or the unit providing care can email directly. Once the MWD Trauma Registry is online, the first veterinary unit will input the information into the registry and scan the cTCCC card to upload into ROVR. The cTCCC card becomes part of the canine's permanent DoD medical record. For US Special Operations Command (SOCOM) canines, the cTCCC card will be filled out and returned to the handler or operator. The handler or operator will route the card to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.

PAGE 1:

GENERAL INSTRUCTIONS

- To be completed by the handler, human medical provider, veterinary technician or veterinarian fulfilling the role at the point of injury.
- Time Zones: Record all time local 24 hour military format, hh:mm
- A+ (plus sign) means positive test result; a - (minus sign) means negative test result.

EVACUATION CATEGORY (mark as appropriate)

URGENT – Patient who should be evacuated as soon as possible and within **two** hours to save life, limb or eyesight

PRIORITY – Patient who should be moved within **four** hours or their condition will deteriorate to such a degree that will be urgent

ROUTINE – Patient whose condition is not expected to worsen significantly and who will require evacuation in the next **24** hours

EVACUATION MODE & TYPE (mark as appropriate)

PATIENT IDENTIFICATION

UNIT. Record the unit the canine is assigned

ANIMAL NAME. (self-explanatory)

TATTOO. (self-explanatory)

BREED. (self-explanatory)

DATE. (DD-MM-YY)

TIME. Record all time local 24 hour military format, hh:mm

BLOOD. DEA 1.1 (mark as appropriate if known)

GENDER. (mark as appropriate)

MECHANISM OF INJURY (mark as appropriate – use other for DNBI or if unknown – describe)

INJURY (mark the diagram where the trauma/injury or disease is located – if there are more than one injury, identify each with the mechanism of injury)

General Instructions for Canine Trauma Combat Casualty Care Card

VITAL SIGNS (input vital signs at least hourly)

FIRST RESPONDERS (self-explanatory)

PAGE 2:

TREATMENTS (mark as appropriate)

C (circulation): self-explanatory

A (airway): self-explanatory

B (breathing): self-explanatory

FLUIDS (fill out as appropriate and complete as possible)

MEDICATIONS (MEDS) (fill out as appropriate and complete as possible – if other medications are given that aren't mentioned on the form, please include whether they are an analgesic, antibiotic or TXA. Be as thorough as possible)

OTHER (Include other lifesaving techniques or treatments)

NOTES (Include any additional information (location/country, euthanized/KIA, treatment regiments that were used to the treat the patient, etc.)

DISPOSITION OF THE FORM – (The form is to be kept with the patient until it can be put into the patient's record.) Pass the card to the next treatment facility. 1) Scan and email the card to dog.consult@us.af.mil . 2) Put the card into the patient's hard copy record. CAVEAT: For US Special Operations Command (SOCOM) canines, the cTCCC card will be filled out and returned to the handler or operator. The handler or operator will route the card to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.

DEFINITIONS
IED – Improvised explosive device
GSW – Gunshot wound
TQ – Tourniquet
ET – Endotracheal tube
TXA – Tranexamic acid

General Instructions for Canine Treatment and Resuscitation Record

PURPOSE: The Canine Treatment and Resuscitation Record is for documenting a canine's illness or traumatic injuries and related medical treatment and resuscitation care provided at DOD veterinary medical treatment facility (VTFs) or medical treatment facilities (MTFs). It is to be used at all DoD VTFs & MTFs which have a surgical capability or emergency department (ED). It is also to be used to document all instances of Disease Non-Battle Injury (DNBI) seen at Role II VTFs. In cases of DNBI, complete only the applicable sections. A canine trauma patient is defined as a canine who has an injury or illness with the potential of requiring a surgical intervention. The form is comprised of two parts. Part I, Nursing Flow Sheet is completed by the veterinary technician or nurse fulfilling the role as a scriber or the nurse providing bed side care. Part II, Physician H&P (History and Physical) is completed by the trauma veterinarian or physician providing care for the patient. The Canine Treatment and Resuscitation Record becomes part of the patient's permanent DOD medical record. For US Special Operations Command canines, the Canine Treatment and Resuscitation Record will be filled out and returned to the handler or operator. The handler or operator will route the record(s) to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.

PART I: ANIMAL TECHNICIAN / NURSING FLOW SHEET

GENERAL INSTRUCTIONS

- To be completed by the technician / nurse fulfilling the role as a scriber or the technician / nurse providing care.
- Time Zones: Record all time local 24 hour military format, hh:mm
- A + (plus sign) means positive test result; a - (minus sign) means negative test result.
- Record date on top of each page. The date should be the day when care is initiated. If the dog receives multiple days of care, use a new, correctly dated form each day.

PATIENT IDENTIFICATION (at bottom of each page). As stated.

NAME. Name of the Military Working Dog (MWD)

TATTOO. Tattoo identifier (located on the inner surface of the MWD's left ear)

MICROCHIP #. Nine, 12 or 15 digit number specific to the MWD. Record if known or scan if available.

DOB. Date of Birth as listed on the record or in the Remote Online Veterinary Record (ROVR)

AGE. Dog's age in years

GENDER. Male, Female, Neutered (used for both genders)

BREED. Dog's breed as listed on the record or in ROVR. Recognized abbreviations are acceptable (e.g. German Shepherd Dog – GSD, Dutch Shepherd – DS, Belgian Malinois – B Mal, Labrador Retriever – Lab)

MWD TYPE. MWD's type of service, e.g. PEDD, SSD, MPC, IEDD

HANDLER NAME. Name of the person accompanying MWD

DEPLOYED / ASSIGNED UNIT. MWD's owning unit

VET / TECH / HCP NAME. Name of the person responsible for the care of the MWD.

VET / TECH / HCP SIGNATURE. Signature of the responsible provider completed after reviewing the form for accuracy and completeness.

FACILITY NAME. Record your VTF or MTF unit identifier

FACILITY LOCATION. Record FOB, COB, or geographic site

1.0 PATIENT / CANINE INFORMATION

1.1 TRAUMA TEAM DATA. As stated. Record all time local 24 hour military format, hh:mm

General Instructions for Canine Treatment and Resuscitation Record

1.2 ARRIVAL. As stated.

1.3 EVAC FROM. Check all that apply. Location is the facility name.

1.4 MODE OF ARRIVAL. Check one.

WALKED/CARRIED. As stated.

CASEVAC – Air. Casualty Evacuation via non-medical rotary wing aircraft.

CASEVAC – Ground. Casualty Evacuation via non-medical ground transport vehicle.

MEDEVAC - Air includes DUSTOFF. Medical Evacuation via helicopter. Record mission number when known.

MEDEVAC – Ground. Medical Evacuation via ambulance. Record mission number when known.

CCATT. Critical Care Air Transport Team.

SHIP EVAC. Evacuation via US Navy vessel.

AE. Aeromedical Evacuation. Casualty Evacuation via USAF fixed-wing aircraft.

If Other, describe the method by which the patient arrived, such as USAF Pararescue (PJ or Pedro) or United Kingdom Medical Emergency Response Team (MERT), but not DUSTOFF.

1.5 INJURY TYPE. Check all that apply.

1.6 INJURY CLASSIFICATION. Check one.

1.7 TRIAGE CATEGORY. Check one.

Immediate - Patients who require rapid, immediate intervention in order to preserve life and/or limb AND are likely to survive because of the intervention--damage control surgery (e.g.: respiratory obstruction, unstable casualty with chest or abdominal injuries, uncontrolled hemorrhage, hypovolemic shock, emergency amputation).

Delayed - Patients who require surgery or other specific therapeutic intervention, but who will not be severely compromised if the intervention is delayed to a later time (e.g. closed fracture without neurovascular compromise, moderate burns of < 50% TBSA, large muscle wounds, intra-abdominal and/or thoracic wounds).

Minimal - Non-Urgent: Minor Injuries; MWD can be safely cared for by veterinary staff or be monitored by handler. (e.g. Minor lacerations, abrasions, fractures of digits/distal tail, and minor burns). Can safely wait 12-24 hours or longer for care.

Expectant - Patients whose injuries are so severe that even with the benefit of optimal medical resources, their survival would be unlikely (e.g. massive open head injury with brain matter present, high spinal cord injuries, mutilating explosive wounds involving multiple anatomical sites and organs, second/third degree burns in excess of 60% TBSA, profound shock with multiple injuries and agonal respirations).

1.8 SAFETY. Check all that apply.

1.9 PATIENT CATEGORY. Check one.

USA MWD. United States Army-owned MWD

USAF MWD. United States Air Force-owned MWD

USMC MWD. United States Marine Corps-owned MWD

USN MWD. United States Navy-owned MWD

USCG MWD. United States Coast Guard-owned MWD

Contractor MWD. Specify Contractor Company

General Instructions for Canine Treatment and Resuscitation Record

NATO-Coalition MWD. NATO country military forces-owned MWD. Specify country.

Non-NATO Coalition MWD. Non-NATO military forces-owned MWD. Specify country.

Other. If Other, describe the patient's classification as it relates to military, government or civilian organizations.

1.10 PERSONAL PROTECTIVE EQUIPMENT (PPE). Check all that apply. Collect the PPE and ensure it is transported with the canine.

1.11 INJURY CAUSE. Check all that apply. If Other, describe cause of the injury.

IED. Improvised Explosive Device

MVC. Motor Vehicle Crash

GSW. Gunshot Wound

UXO. Unexploded Ordinance

CBRNE. Chemical, Biological, Radiological, Nuclear and Explosives. Specify

Mortar/Rocket/Artillery Shell. Includes Indirect and Direct Fire

2.0 CARE DONE PRIOR TO ARRIVAL

GENERAL INSTRUCTIONS

- Information for this section should be taken from any medical records that accompany the MWD. This may include a Canine - Tactical Combat Casualty Card (cTCCC), SF 600 notes, ROVR digital medical records (eNOTE), or handler recollection. Complete as thoroughly and with as much detail as possible.
- Time Zones: Record all time local 24 hour military format, hh:mm
- A + (plus sign) means positive test result; a - (minus sign) means negative test result.

2.1 PREHOSPITAL TOURNIQUET. Check all that apply.

CAT. Combat Application Tourniquet.

SOFFT. Combat Application Tourniquet

Other. If other, describe the type of tourniquet.

Effective. An effective tourniquet controls active hemorrhage. May be combined with a dressing.

2.2 PREHOSPITAL VITALS. As stated.

SpO2. Do not attempt to obtain an O2 saturation measurement from the lip or tongue of an unsedated MWD. Use the prepuce, vulva, toe webbing or ear pinna as an alternate location.

2.3 HEMORRHAGE CONTROL. Check all that apply.

Celox. Granules, applicator or gauze. Stops bleeding by bonding with red blood cells and gelling with fluids to produce a sticky pseudo clot. This clot sticks to moist tissue to plug the bleeding site. Celox is made with chitosan, a natural polysaccharide.

ChitoFlex. A stuffable wound dressing conducive to narrow wound tracks.

Combat Gauze. Combat Gauze™ is a 3-inch x 4-yard roll of sterile gauze. The gauze is impregnated with kaolin, a material that causes the blood to clot.

Direct Pressure. Pressure applied directly to a wound, usually with sterile, low-adherent gauze between the wound and source of bleeding.

Field Dressing. A casualty's dressing applied to a wound to control hemorrhaging.

QuikClot. Emergency dressing, combat gauze, interventional bandage, QuikClot ACS+™, QuikClot 1st Response™. When QuikClot® comes into contact with blood in and around a wound, it takes in the

smaller water molecules from the blood. The larger platelet and clotting factor molecules remain in the wound in a concentrated form. This promotes rapid natural clotting and prevents severe blood loss.

None. Check if no hemorrhage control measures.

Unknown. Check if hemorrhage control measures are unknown.

Other. Describe the not otherwise specified hemorrhage control measure.

2.4 PREHOSPITAL WARMING. Check all that apply.

HPMK. Hypothermia Prevention and Management Kit. Check only if all three components were used: Hat/Hood, Activated Liner, and Outer Shell.

If Other. Describe the not otherwise specified warming device.

2.5 PREHOSPITAL MEDS. Enter medication, dose and route.

2.6 PREHOSPITAL INTERVENTIONS. As stated.

IO Infusions. Intra-osseous administration of fluids

IV Fluids. Intravenous administration of fluids

E-Collar. Elizabethan collar. One of a number of devices placed around the neck of a MWD to prevent licking or chewing at a wound or device. May be a commercial product or a bucket with the bottom removed.

Pain Scale. See Table 1 for the explanation of how to determine pain in a MWD

CPR. Cardiopulmonary resuscitation

3.0 PRIMARY ASSESSMENT

3.1 VITALS. As stated. For Pain Scale, enter level that you estimate the dog to be experiencing. Zero indicates the least pain; four is the most severe pain. See Table 1.

TABLE 1. CANINE PAIN SCALE

Score	Behavioral	Palpation	Body Tension
0	Comfortable when resting	Nontender to wound palpation	Minimal
1	Slightly unsettled or restless	Reacts to wound palpation	Mild
2	Uncomfortable at rest, whimpers, licks at wound	Flinches, whimpers, cries	Mild to Moderate
3	Unsettled, crying, groaning, biting, chewing wound	Increased respiratory rate, sharp cry, growl	Moderate
4	Constantly groaning or screaming when unattended, may bite wound	Cries at non-painful palpation, may react aggressively	Moderate to Severe

3.2 NEURO / MENTAL STATUS. As stated. If Other, describe the not otherwise specified.

HYPERACTIVE. Stressed, overly-excited MWD that is alert and conscious but will not follow commands due to repeated panting, pacing and/or aggression. MWD may exhibit frantic searching behavior or excessive, unfocused aggression. Special care should be taken when handling a hyperactive MWD to avoid being bitten.

ALERT. Characterized by a normal level of consciousness. The MWD responds to external stimuli and is able to follow commands when asked.

SEDATED. As stated. The MWD has been administered sedative medication but was alert or hyperactive

before administration.

DEPRESSED. Characterized by a conscious but lethargic state. The MWD is relatively unresponsive to the environment and tends to sleep when undisturbed. Often caused by systemic problems like fever, anemia or metabolic disease. When associated with a primary brain problem, indicates diffuse cerebral cortex disease.

DISORIENTED. The MWD can respond to its environment but does so in an inappropriate manner. Special care should be taken when handling a disoriented MWD to avoid being bitten.

STUPOR. Characterized by an animal that tends to sleep when undisturbed, and that is not arousable with gentle stimuli like sound or touch. The MWD will respond slightly to painful stimuli and have some voluntary movements.

COMATOSE. Characterized by a state of deep unconsciousness, where the MWD cannot be aroused even with significant painful stimuli. Simple reflexes may still be intact and their presence should not be confused with level of consciousness.

MGCS. Modified Glasgow Coma Scale. See Table 2. Score interpretation: 3 – 8 Grave; 9 – 14 Guarded; 15 – 18 Good.

TABLE 2. CANINE MODIFIED GLASGOW COMA SCALE

Level of Consciousness	**Score**	**Pt Score**
Occasional periods of alertness and responsive to environment	6	
Depression or delirium, capable of responding to environment but response may be inappropriate	5	
Stupor, responsive to visual stimuli	4	
Stupor, responsive to auditory stimuli	3	
Stupor, responsive only to repeated noxious stimuli	2	
Coma, unresponsive to repeated noxious stimuli	1	
Motor Activity		
Normal Gait, normal spinal reflexes	6	
Hemiparesis, tetraparesis, or decerebrate activity	5	
Recumbent, intermittent extensor rigidity	4	
Recumbent, intermittent extensor rigidity with opisthotonus	3	
Recumbent, constant extensor rigidity with opisthotonus	2	
Recumbent, hypotonia of muscles, depressed or absent spinal reflexes	1	
Brainstem Reflexes		
Normal pupillary light reflexes and oculocephalic reflexes	6	
Slow pupillary light reflexes and normal to reduced oculocephalic reflexes	5	
Bilateral unresponsive miosis with normal to reduced oculocephalic reflexes	4	
Pinpoint pupils with reduced or absent oculocephalic reflexes	3	
Unilateral, unresponsive mydriasis with reduced or absent oculocephalic reflexes	2	
Bilateral, unresponsive mydriasis with reduced or absent oculocephalic reflexes	1	

3.3 HYPO / HYPERTHERMIA CONTROL MEASURES. As stated. Other includes Body Bag.

3.4 AIRWAY. As stated.

OPA. Oral Pharyngeal Airway

BVM. Bag-Valve-Mask (Ambu bag)

General Instructions for Canine Treatment and Resuscitation Record

3.5 BREATHING. As stated.

3.6 NOTES. As stated.

3.7 CIRCULATION. As stated. Use caution when assessing the mucous membranes of a MWD. If unsedated or variably conscious, ask the handler to show you the mucous membrane color and perform the CRT evaluation. Also consider using an alternate location to approximate CRT. The mucosa of the conjunctiva, prepuce or vulva are acceptable alternative locations to evaluate CRT.

4.0 SECONDARY SURVEY

4.1 HEAD / NECK ENT. As stated.

JVD. Jugular Venous Distention

NR. Non-Reactive

4.2 HEART.

Rhythm. As stated. If Other, describe not otherwise specified rhythm.

NSR. Normal Sinus Rhythm

PEA. Pulseless Electrical Activity

V-Fib. Ventricular Fibrillation

V-Tach. Ventricular Tachycardia

Pulses. Enter S, W, D, A as appropriate. Doppler includes non-palpable, but detected with Doppler. Absent means no pulse, non-palpable and not detected with Doppler.

4.3 ABDOMINAL. As stated.

FAST. Focused Assessment with Sonography for Trauma. Check + (plus) if fluid present.

Check – (minus) if no fluid present. Check in the appropriate block if fluid is identified in

the evaluated quadrant. Leave blank if not performed.

DH. Diaphragmatic-Hepatic

CC. Cysto-Colic

SR. Spleno-Renal

HR. Hepato-Renal

4.4 EXTREMITIES. Check all that apply. To evaluate for Motor in an extremity: once the MWD has been cleared for spinal fracture, then assist to stand if necessary and evaluate each leg for motor as the dog is walked. If the MWD cannot be walked, then touch each paw and evaluate the response. While testing a recumbent dog, do not confuse the withdrawal reflex with motor function. To evaluate for Sensation in a MWD: superficial pain can be elicited by gently pinching between the toes and watching for a head turn or growl; deep pain is assessed by clamping a digit firmly with hemostats until a response is seen. For Pulses Present (positive) enter S, W, D, or A. Doppler includesnon- palpable, but detected with Doppler. Absent means no pulse, non-palpable and not detected with Doppler.

4.5 ALLERGIES. Check one. NKDA is No Known Drug Allergies. If Other, describe not otherwise specified allergy.

4.6 CURRENT MEDICATIONS. As stated. Current Meds: List medication, dose and route.

4.7 MEDICAL HISTORY. As stated.

4.8 PROCEDURES. As stated. Hemorrhage Control Measures. Refer to Prehospital Hemorrhage Control Measures.

NOTE: In the 'performed by' block, in addition to name, record the Title / AOC / MOS / Rate of the person performing each intervention.

ET Intubation. Endotracheal Intubation. List endotracheal tube size if used. List tracheostomy tube size if used. Check block if End Tidal CO2 (ETCO2) changes post-intubation. Check block if patient has bilateral breath sounds (BBS) post-intubation.

General Instructions for Canine Treatment and Resuscitation Record

Chest Tube. 75% of MWDs have a fenestrated mediastinum so both sides of the chest should be tapped if there is significant pneumothorax.

4.9 VENT SETTINGS.

MODE. Manual or Mechanical

FiO2. Fraction of inspired O2. Start at 100% then reduce to <60%

Rate. Number of breaths delivered per minute. For MWDs, set between 8 – 20 bpm to maintain end tidal CO2 between 35 – 45 mmHg

PEEP. Positive End-Expiratory Pressure. For normal lungs 0 -2 cmH2O; for abnormal lungs 2 – 8 cmH2O

TV. Tidal Volume. To calculate tidal volume in a MWD: 15 x BW (kg) = mL TV

Notes. As stated

4.10 INTRAVENOUS / INTRAOSSEOUS ACCESS AND FLUIDS / BLOOD PRODUCTS. As stated. Initials: Legible initials of person who performed task. Enter time as stated.

4.11 MEDICATIONS. As stated. Initials: Legible initials of person who performed task.

4.12 LABS. As stated. Enter time as stated.

CBC. Complete Blood Count

Chem 7. Actual test will vary based on location and available equipment. Typically includes Sodium (Na), Potassium (K), Chloride (Cl), Bicarbonate (HCO3), Blood Urea Nitrogen (BUN), Creatinine (Cr), and Glucose

Chem 12. Actual test will vary based on location and available equipment. Typically includes the tests in a CHEM 7 plus Alkaline Phosphatase (ALP), Alanine aminotransferase (ALT), Aspartate aminotransferase (AST), Bilirubin, Total Protein, Albumin and Calcium (Ca).

H&H. Hematocrit and Hemoglobin

ABG. Arterial Blood Gas

VBG. Venous Blood Gas

PT / PTT. Prothrombin Time / Partial Thromboplastin Time

INR. International Normalized Ratio

U/A. Urinalysis

4.13 CT. As stated. Enter time as stated.

4.14 X-RAY. Enter time as stated.

4.15 PENDING STUDIES. Record any additional tests that have been ordered or completed if there is not adequate space in 4.12 LABS, 4.13 CT or 4.14 X-RAY.

4.16 RESULTS. As stated. Excludes results for labs, CT and X-Ray that should be recorded in Part II, Section 2 Laboratory Results and Section 3 X-RAYS and CT

4.17 VITAL SIGNS. As stated.

ICP. Intracranial Pressure Measurement

4.18 DISPOSITION. Describe patient disposition. If death, complete Part II, section 8.3 Death Information. For mode of transport, refer to section 1.4 Mode of Arrival. If no additional information will be completed on this form, refer to the Completion Instructions on Page 10 for instructions on how to finalize and submit this form.

VMCE. Veterinary Medical Center Europe

4.19 NOTES. Enter additional information relevant to the patient's nursing care.

PART II: VETERINARIAN / PHYSICIAN H&P

GENERAL INSTRUCTIONS:

- To be completed by the veterinarian / trauma physician providing care for the patient.
- Time Zones: Record all time local 24 hour military format, hh:mm

General Instructions for Canine Treatment and Resuscitation Record

- A + (plus sign) means positive test result; a - (minus sign) means negative test result.
- Record date on top of each page. The date should be the day when care is initiated. If the dog receives multiple days of care, use a new, correctly dated form each day.

PATIENT IDENTIFICATION (at bottom of each page). As stated.

NAME. Name of the Military Working Dog (MWD)

TATTOO. Tattoo identifier (located on the inner surface of the MWD's left ear)

MICROCHIP #. Nine, 12 or 15 digit number specific to the MWD. Record if known or scanner available

DOB. Date of Birth as listed on the record or in the Remote Online Veterinary Record (ROVR)

AGE. Dog's age in years

GENDER. Male, Female, Neutered (used for both genders)

BREED. Dog's breed as listed on the record or in ROVR. Recognized abbreviations are acceptable (e.g. German Shepherd Dog – GSD, Dutch Shepherd – DS, Belgian Malinois – B Mal, Labrador Retriever – Lab)

MWD TYPE. MWD's type of service, e.g. PEDD, SSD, MPC, IEDD

HANDLER NAME. Name of the person accompanying MWD

DEPLOYED / ASSIGNED UNIT. MWD's owning unit

VET / TECH / HCP NAME. Name of the person responsible for the care of the MWD.

VET / TECH / HCP SIGNATURE. Signature of the responsible provider completed after reviewing the form for accuracy and completeness.

FACILITY NAME. Record your VTF or MTF unit identifier

FACILITY LOCATION. Record FOB, COB, or geographic site

1.0 HISTORY & PHYSICAL – INJURY DESCRIPTION

1.1 ARRIVAL. As stated.

1.2 TRIAGE CATEGORY. Check one. Refer to 1.7 for definitions from Part I Animal Care Technician / Nursing Flow Sheet.

1.3 CHIEF COMPLAINT, HISTORY AND PRESENTING ILLNESS. As stated.

1.4 INJURY DESCRIPTION. As stated. Annotate on the diagram using the appropriate injury abbreviation. Doppler includes non-palpable, but detected with Doppler. Absent means no pulse, non-palpable and not detected with Doppler. Calculate %TBSA using the guide in section 1.8.

1.5 HISTORY AND PHYSICAL. As stated. Interventions Prior to Arrival is any intervention performed in a prehospital or transferring facility.

1.6 PRE / INITIAL PROCEDURES / DIAGNOSTICS. As stated. Pre means prior to arrival.

Pericardial FAST. Check if presence of fluid or free air. Describe findings as needed.

Thoracic FAST. Check if presence of fluid or free air at Left or Right Chest Tube Site (CTS).

Pericardiocentesis. Check block if performed and record volume of fluid obtained in the space below to distinguish from fluid or blood obtained from the thorax.

DPL. Diagnostic Peritoneal Lavage. Describe technique, locations attempted / performed and findings.

Serial AFAST. Refer to Part I, section 4.3 Abdominal for location definitions.

Front / Rear Extremities. As stated. Also record and describe if other type of bandage is placed.

Seizure Protocol. Control seizures that develop with diazepam or midazolam (0.3 mg/kg; IV, IO, or intranasally), repeated every 15-30 minutes if necessary. If available, give phenobarbital (15 mg/kg IV or IO) loading dose, and 2.5 mg/kg IV every 12 hours thereafter if seizures persist or status epilepticus develops.

Central Line. Describe location, catheter size and number of ports.

Intraosseous / Intravenous Catheter. Describe location and catheter size.

General Instructions for Canine Treatment and Resuscitation Record

1.7 PUPILS / VISION. As stated.

1.8 BURN. As stated. Describe the cause of burn.

% TBSA. Percent of Total Body Surface Area affected. Head: 9%; Thorax: 18%; Abdomen: 18%; Forelimb: 9% each; Hindlimb: 18% each.

Super. Superficial – First Degree.

Super PT. Superficial Partial Thickness – Second Degree.

Deep PT. Deep Partial Thickness – severe Second Degree.

Full. Full Thickness – Third Degree if injury limited to the skin and subcutaneous tissues. Fourth Degree if the burn involves muscle and bone.

1.9 EXTREMITIES. As stated. Evaluate and record Motor, Sensory and Range of Motion (ROM) for each extremity.

2.0 LABORATORY RESULTS

2.1 CBC. As stated.

2.2 CHEMISTRY 7/12 (14). As stated. Refer to Part I, Section 4.12 for abbreviation descriptions.

2.3 PT / PTT / INR. Prothrombin Time / Partial Thromboplastin Time / International Normalized Ratio. As stated.

2.4 BLOOD TYPE. Record if patient is DEA 1.1 positive or negative. Record full blood type if known.

2.5 VBG / ABG. Venous Blood Gas / Arterial Blood Gas. As stated.

2.6 URINALYSIS. As stated.

SpGr. Urine Specific Gravity. Canine USG should be measured on a refractometer, as urine test strips are not always accurate.

LEU. Leukocytes

PRO. Protein

GLU. Glucose

KET. Ketones

UBG. Urobilinogen

BIL. Bilirubin

HGB. Hemoglobin

2.7 OTHER LABS. Record any additional labs performed and appropriate results.

3.0 X-RAY AND CT

3.1 CT OBTAINED. As stated.

3.2 X-RAYS OBTAINED. As stated.

3.3 FOREIGN BODY. Check all that apply. Collect the foreign body and save. More guidance will be forthcoming on where to send.

3.4 PENDING STUDIES. As stated.

3.5 RESULTS. As stated. Include TEG / Rotem results if performed. Refer to the CPG to evaluate canine TEG results.

4.0 IMPRESSION / ASSESSMENT

Enter impressions and findings.

4.1 SEVERITY. (mark the most appropriate)

4.2. IMPRESSION/ASSESSMENT COMMENTS (fill in as appropriate)

5.0 DIAGNOSES

Enter diagnoses and findings, up to 12. If more than 12, record the most life-threatening findings.

General Instructions for Canine Treatment and Resuscitation Record

6.0 PLAN

6.1 PLAN. Enter the treatment plan and any additional procedures that were or will be performed.

7.0 DNBI / NBI CATEGORY

Check all Disease Non Battle Injuries/Non Battle Injuries that apply. Describe any injury not otherwise specified.

8.0 CAUSE OF DEATH

If death, complete all appropriate sections. Leave blank if patient is alive.

8.1 ANATOMIC. As stated. If Other, describe not otherwise specified anatomy.

8.2 PHYSIOLOGIC. As stated. If Other, Specify, describe not otherwise specified physiology.

MOF. Multi Organ Failure

CNS. Central Nervous System Failure

8.3 DEATH INFORMATION.

Euthanized. Record medication(s) used, volume administered and route. Compete Canine Death Certificate (DD Form 1743).

Necropsy by DVM. Record necropsy date and time (local). Record time between death and start of necropsy if known. Estimate time if unknown.

Gross Pathology Report. Annotate if a gross necropsy was performed, and gross pathology report (DD Form 1626) was completed, and if samples were submitted to the Joint Pathology Center (JPC) or other pathology center. Record where the tissue samples were submitted and date of submission if known.

Death Remarks. Annotate any other information that may be pertinent to the patient's case.

CANINE TREATMENT AND RESUSCITATION RECORD COMPLETION AND SUBMISSION

- After the form has been completed, it should be reviewed by the responsible HCP listed in the Patient Identification block for completeness and detail. The responsible HCP should then sign each page.
- The signed form needs to be submitted to the DOD Military Working Dog Veterinary Services DAILY by clicking on one of the 'Submit by Email' buttons located on the bottom of each page. If the button does not work, then submit the form to dog.consult@us.af.mil. The subject line should include the MWD Name, Tattoo and Date, i.e. 'Canine Treatment and Resuscitation Record MWD Ayaks L332 16 August 2018'. For US Special Operations Command canines, the Canine Treatment and Resuscitation Record(s) will be filled out and returned to the handler or operator. The handler or operator will route the record(s) to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.
- A printed copy of each signed form MUST be included in the MWD's paper record to ensure continuity of care, especially if the dog will be transferred to another level of care.
- A completed copy of the record will be uploaded into the MWD's ROVR record when access is available. This should happen in theater if possible, but if ROVR access is not available, then all records need to be uploaded at the first Role III facility or at the MWD's home station veterinary clinic.
- To upload a form in ROVR:
    - Open the MWD's record, select Imported Files from the Patient Tools menu on the right
    - Select the Upload File button in the upper left hand corner of the screen
    - Find the appropriate file by selecting the browse button, then complete each field. Document date is the date listed on the Treatment and Resuscitation Record. Document Type should be 'Other' and Specialty should be 'Emergency Care.' In the Comments, record as 'Canine Treatment and Resuscitation Record'. Select Upload to finish.
    - Repeat as necessary for each completed record.

PROTOCOLS APPROVAL

The Search and Rescue Medical Program Directors (MPD) have approved this document as Standing Orders of patient treatment protocols for Rescue Swimmers (RS), EMT-Basics, Search and Rescue Medical Technicians (SMT), Paramedics (EMT-P), and Critical Care Paramedics. Medicine is a practice, ever changing, and requires updates. To keep up with medical advancements, each section should be reviewed and updated as appropriate; at a minimum, every 2 years or upon change of the Medical Director. Changes and revisions will be issued only after approval from the Medical Director.

This document is *not* intended to be a comprehensive patient care manual. Rather, it specifies standard operation procedures (SOP) and treatment protocols to operate under emergency medical conditions without the direct supervision of a Medical Director.

The introduction and Administrative sections establish the standard by which personnel shall abide. All other sections are designed for use by basic and advanced providers. While they should be followed, there is no substitute for logical thinking, common sense, and professional performance by the provider employing them. Mission requirements or a patient's emergency condition may require the provider to deviate from the stated protocol without the benefit of immediate access to medical direction. Under such circumstances, deviations should be limited to the provider's level of training, common sense, and the dictum "Primum Non Nocere" ("First, do no harm").

Each treatment protocol presents the basic life support tasks separate from the advanced life support tasks. This was done so providers have a sensible order of patient treatment. In the event a provider responds to an unusual case, or where the illness or injury does not fall into a treatment protocol, the provider will seek directives from Medical Control. If Medical Control is unavailable, the provider shall apply aforementioned skills with common sense and seek to maintain Airway, Breathing, and Circulation. Remember, start with the basics and fall back on the basics.

CDR Benjamin Walrath MD/USN NPI# 1356497168 _____ Date: 14 DEC 2017

LCDR Paul Roszko MD/USN NPI# 1639499544 _____ Date: 14 DEC 2017

"PRIVACY ACT PROTECTED – FOR OFFICIAL USE ONLY"

INTRODUCTION TO NAVAL AVIATION MEDICAL TREATMENT PROTOCOLS:

This document has been prepared for use by Emergency Room Physicians, Aviation Medical Director's / Naval Hospital flight surgeons, and Search and Rescue Medical Technicians (SMT), who are engaged in the conduct of Search and Rescue with Air Medical Transport (AMT) operations, Aero-Medical Evacuation (MEDEVAC), and Tactical Evacuations (TACEVAC).

This document is intended to provide a consistent framework of medical treatment guidelines for Naval Aviation Search and Rescue, as discussed on the following page. The document has been created to reflect current prehospital medical trends. It has been adapted for use by the Search and Rescue (SAR) Medical Technician (SMT/NEC L00A), SMT Paramedics, Rescue Swimmers, and EMT-Rescue Swimmers providing medical care. No protocol template can address every eventuality or medical condition in a universally accepted format. The basic protocols provided in this document will, however, provide a consistent set of medical treatment standards that can be delegated from the Medical Director to the infield providers. Protocols provide consistent standards for training and performance improvement monitoring: they are one of the cornerstones of every EMS system development.

The SMTs possess varying levels of experience from the recently qualified SMT with National Registry of Emergency Medical Technician (NREMT)-Basic (NREMT) certification up to the SMT with NREMT-Paramedic certifications. Between the Basic EMT and the Paramedic lies the nebulous EMT intermediate (which has no consistent skill set from state to state). Each SMT possesses a different skill proficiency level depending on his/her previous experience and patient care history. Unlike the civilian Paramedic who uses his/her skills on a daily basis, the SMT may only use his/her skills occasionally for actual patient care in the station SAR environment. All SMTs have received training and certifications in Intravenous therapy, however it is encouraged and recommended that all SMTs receive continuing education on ALS classes to include; Advanced Cardiac Life Support (ACLS), Advanced Pre-Hospital Trauma Life Support (PHTLS), Tactical Combat Casualty Care (TCCC), Pediatric Advanced Life Support (PALS), Pediatric Education for the Prehospital Provider (PEPP), Neonatal Resuscitation Provider (NRP) and Operational Emergency Medical Services (OEMS).

The Rescue Swimmers and Rescue Swimmer/EMT possess a base knowledge of first responder/EMT Basic qualification. Their skill set is a tremendous help in the triage, treatment, and turnover of patients. Each Rescue Swimmer/EMT medical capabilities is covered in these protocols.

The intent of these protocols is to allow all of the SAR Members to best utilize the skills that they do currently possess to treat their patients. This is dependent on the validation of any advanced skills (such as endotracheal intubation, cricothyroidotomy, chest decompression, advanced cardiac life support and pharmacology) at the unit level by the Petty Officer designated by the Medical Director or Commanding Officer as the Standardization Petty Officer. SAR Members will perform only those skills with which he/she is proficient. If he/she is not proficient in a skill that he/she has been taught or if he/she is not confident with his/her ability to correctly perform a procedure, he/she will consult his/her Standardization Petty Officer for further training. Regular training and practice will be ongoing, so there should be ample opportunity to become proficient and confident with all of the skills detailed in these protocols!

In practical terms, this means providing care IAW the guidance above without deviation. If there is a needed deviation, your medical director is responsible for any directed deviation during on-line Medical Control. If you provide care outside the scope of your practice during off-line Medical Control, you are personally responsible for any adverse outcome. *DO NOT PROVIDE CARE THAT DEVIATES FROM WHAT YOU ARE TRAINED AND ALLOWED TO DO.*

XII. ***NOTES*** 219

II. ADMINISTRATIVE

1. MEDICAL DIRECTOR

The Medical Director should be a licensed physician and Emergency Room physician, or Trauma Surgeon, or EMS Director. The Medical Director will advise the Unit's Commanding Officer on all medical components of the Unit's operations as required by the CO. The Medical Director will also serve as medical control authority for all patient care performed by unit SMTs. The Medical Director will be available for consultation, provide retrospective Quality Assurance/Quality Improvement (QA/QI) review, supervise continuing education (CE) programming, and will serve as a medical liaison between this unit and other services, facilities, and physicians. The Medical Director may delegate his or her authority to the senior SAR Medical Technician (typically Standardization PO) as he or she deems appropriate.

ON-LINE Medical Control: A physician is present at the scene or available through communication. Although this is the ideal and preferred method it is uncommon in most Rescue operations. Order of precedence for on-line medical control:

On scene:
Senior Medical Officer (SMO of Ship)
Senior U.S. Military Physician present on scene
Senior Allied Military M.D. (equivalent to US Military Physician)
Civilian M.D. who can prove credentials and assumes responsibility
Senior Military Physician Assistant
Senior SOCM / 18D

Off scene:
U.S. Military Physician in direct contact via audio/visual communication

Off-line Medical Control: Contact with a Physician is impossible or impractical. Care is based on approved protocols and procedures. This is the most common scenario.

In Off-line control situations,

Note: These sources cover the vast majority of care you will provide. Instances where deviation may occur more frequently would be in remote situations where certain medications are not available, and the local medical authority has directed the use of locally available meds, and has provided the adequate in-service education with proper documentation. Also, certain regions may have diseases and treatments that are endemic and require unique care that should be added to the protocols in that area of operation.

2. STANDING ORDERS/TREATMENT PROTOCOLS

Designated SMTs will maintain professional certifications, continuing medical education, and military credentials in accordance with OPNAVINST 3130.6 series, the National Registry of Emergency Medical Technicians, and local command directives.

II. ADMINISTRATIVE

A. Skill Sets:

Skill	Rescue Swimmer (RS)	RS / EMT	SMT	EMT-P
Airway				
Oral/Nasalpharyngeal Airway		x	x	x
L.M.A or Combi-tube			x	x
King Airway			x	x
Magill Forceps Use			x	x
CPAP/Bipap			x	x
Cricothyrotomy			x	x
Chest Decompression			x	x
Finger Thoracotomy / Chest Tube				FP-C / TP-C
Automated Ventilator			x	x
Bag Valve Mask	x	x	x	x
Pocket Mask	x	x	x	x
Circulatory Support				
Peripheral IV			x	x
Intraosseous Cannulation			x	x
External Jugular Cannulation			x	x
Glucometry		x	x	x

Defibrillation - Automatic/Manual			x	x
Synchronized Cardioversion			x	x
Pacing			x	x
Vital Signs - Automatic/Manual		x	x	x
Medications				
Assisted Medications		x	x	x
Inhaled Medications - Nebulizer			x	x
IM Medications			Limited	x
IV Medications			Limited	x
IO Medications			Limited	x
PO Medications		x	x	x
SL Medications			x	x
SQ Medications			x	x
Transdermal Medications			x	x
Blood Products				x

II. ADMINISTRATIVE

A. Skill Sets:

All provider levels shall perform

Only qualified SMT's shall perform

SMT's are permitted to perform all skill sets

Only qualified Paramedics shall perform

Paramedics' are permitted to perform all skill sets up to this level.

II. ADMINISTRATIVE

B. SMTs who are QUALIFIED and designated are authorized to utilize, at the discretion of the Medical Director, the following medications:

***** Medications that Highlighted are only for SMT-Paramedic use**
++ Controlled Substance ++

1) Administration of the following medications according to treatment protocols:

Acetaminophen (Tylenol)
Activated Charcoal
Adenosine (Adeonocard)
Albuterol 0.5%
Amiodarone
Aspirin
Atropine Sulfate
Calcium Chloride
Calcium Gluconate
Cefazolin Sodium (ANCEF)
Ceftraixone (Rocephin)
Dextrose 25% / 50%
Dexamethasone
Diamox
Diazepam (Valium) ++
Diltiazem ++
Diphenhydramine (Benadryl)
Dopamine
Ertapenem (INVANZ)
Erythromycin Ophthalmic Ointment
Etomidate
Epinephrine
Fentanyl++
Flumazenil (Romazicon)
Furosemide (Lasix)
Glucagon / Insta Glucose
Hetastarch
Ipratropium
Ketamine ++
Ketorolac
Lactated Ringers (LR)
Lidocaine (Xylocaine)
Lorazepam (Ativan) ++
Magnesium Sulfate 10%
Meloxicam (Mobic)
Methylprednisolone
Midazolam (Versed) ++
Moxifloxacin (Avelox)
Morphine Sulfate ++
Naloxone (Narcan)
Nitroglycerin SL spray / tablets
Ondansetron (ZOFRAN)
Oxymetazoline (Afrin)
Oxygen
Promethazine
Rocuronium
Sodium Bicarbonate
Sodium Chloride 0.9% (NS)
Succinylcholine
Vecuronium
Vasopressin
Thiamine
Terbutaline
Tranexemic Acid (TXA)

2) The following are to be utilized only if the SMT possessed at EMT-P and or FP-C certification. If the SMT does not possess the certification, the SMT shall have at a minimum a nurse or higher during transport.

Blood Products
Fresh Frozen Plasma (FFP)
Freeze Dried Plasma

II. ADMINISTRATIVE

3. Principles of Medical Care:

1. MARCH PAWS: A pneumonic device used to cover the vast majority of care required during medical/tactical field care and medical/tactical Evacuation. It covers the care of any medical/trauma patient. Other than the **"M"**, it covers the care for most medical patients since it is just a variation of the ABC'S. This approach allows for the SAR medical community to treat in an organized manner ensuring he/she doesn't neglect any treatment in the event of a break in care.

M – Massive bleeding
A – Airway
R – Respirations
C – Circulation
H – Head and hypothermia
P – Pain
A – Antibiotics
W – Wounds
S – Splinting

The approach/Treatments below include practices & principles from the NREMT, ATLS, TCCC, PHTLS/ITLS, data from the OCO, Joint Trauma Registry, and past experiences.

2. Principle of the assessment**:**

a. PPE
b. Scene safety & security
c. Mechanism of injury/illness (MOI)
d. # of patients
e. Call for additional resources as applicable
f. General impression
g. **MARCH**:
   - **M** – Tourniquet, hemostatic gauze, pressure dressing, pelvic sling/junctional tourniquet, suture/staple, clamp, direct pressure, junctional hemorrhage device, elevate.
   - **A** – Chin lift/Jaw thrust, recovery position, sit up and lean forward position, NPA, OPA, supra-glottic device, ET tube, cricothyrotomy.
   - **R** – Chest seal, needle decompression, BVM, SpO_2, finger or tube thoracostomy.
   - **C** –Diagnose (Weak or absent radial pulse, decreased mental status) and treat shock.
   - **H** – Head; diagnose increased intracranial pressure (AVPU, pupils, posturing, irregular respirations, $EtCO_2$). Treatment; Secure the airway, IV/IO. Keep B/P >100, SpO_2 >93%, $EtCO_2$ 30-35 mmHg.
   - **H** – Hypothermia; Dry patient, insulate from the ground, casualty blanket, HPMK, hat.

h. Vital Signs – AVPU, HR, BP, RR, SpO_2%, $EtCO_2$%, Temp. Blood Sugar, 4 Lead / 12 Lead (as applicable)
i. Secondary survey (**PAWS**) – head to toe: DCAP-BTLS, LOBOS, TIC, step in/off
   - **P** – Pain Meds as applicable per protocol.
   - **A** – Antibiotics – PO or IV/IO, for all open combat wounds.
   - **W** – Wounds – clean (remove debris, irrigate) and dress.
   - **S** – Splinting- Perform orthopedic related care, address ortho/PMS; SAM, KTD, spinal immobilization (per protocol), rigid eye shield.
j. Reassess – every 5 minutes for critical / 15 minutes for non-critical / as needed / feasible.
k. Document – Casualty card, medical report.
l. Package for evacuation / transport.

II. ADMINISTRATIVE

4. **Assessment Checklist:**

Scene Size Up

- Scene safety / security
- BSI / PPE
- Determine the mechanism of injury / illness (MOI)
- Determine the # of patients (in case triage is necessary)
- Request additional help if necessary, determine availability of resources
- Verbalize initial impression: "Sick or not Sick

Primary Assessment

- C-Spine as needed unless ruled out
- AVPU
- Massive Hemorrhage – Visualize and feel (sweep) for life threatening hemorrhage:
  - All 4 extremities
  - Junctional Sites (Neck, Axillae, Groins)
  - Torso and back
  - Pelvic stability
- Airway - Open and maintainable (LOBOS)
- Respirations – Assess rate, depth, quality, auscultate lung sounds, apply finger pulse oximeter (as needed or available)
  - Look: Chest rise and fall, paradoxical motion, chest wall injuries.
  - Listen: if possible with a stethoscope.
  - Feel: chest wall: rips, subcutaneous air, holes or defects.
- Circulation – Diagnose shock (Radial / carotid pulse, assess skin color and temp, cap refill).
  - Reassess bleeding control interventions
  - Check pulses for: Rate, strength, and quality
- Head – Rule out severe intracranial pressure (TBI) by identifying mental status, pupils, posturing or snoring respirations.
  - Glasgow Coma Score (GCS)
  - Assess Cranial Nerves
- Hypothermia – Dry and cover patient, use HPMK or blanket/Emergency blanket, insulate from ground.
- Transport decision

Secondary Assessment

- Vital signs - AVPU, HR, BP, RR, SpO_2%, $EtCO_2$%, Temp. Blood Sugar, 4 Lead / 12 Lead (as applicable)
- Head to toe examination:
  - Head: inspect head and face for DCAP-BTLS, reassess airway (LOBOS), ears for drainage, pupils (PERRLA), nose for bleeding and stability, jaw for stability.
  - Neck: Assess for JVD, Subcutaneous air, hematoma, Tracheal deviation, C-Spine deformity / tenderness / Step-off/in.
  - Shoulders/Clavicles: DCAP-BTLS
  - Chest: Expose and inspect, DCAP-BTLS, Reassess the same as primary assessment
  - Abdomen: Normal= soft, flat, non-tender. Assess for tenderness, rigidity, distension, and pulsating masses (TRD-P)
  - Pelvis: Check pelvis once (do not rock), document status of genitals if amputations, priapism.
  - Extremities: DCAP-BTLS, PMS, strength and ROM.
  - Spine: Only log roll if appropriate, DCAP-BTLS, step-off/in.

- Secure to spine board / rescue litter as required.
- Pain – Pain regimen per protocol
- Antibiotic – Antibiotic per protocol
- Wounds – identify potential life threatening wounds
- Splint – perform orthopedic related care as needed.
- Reassess airway / interventions after move or litter placement
- Do not delay transport for IV/IO, drug therapy, or non-critical interventions
- S.A.M.P.L.E / O.P.Q.R.S.T as available.

Documentation and Verbal Report

- Verbal Report:
  - Age
  - Time of incident / illness
  - MOI
  - Signs and symptoms
  - Treatment and interventions
- Written Report:
  - C – Chief complaint
  - H – History
  - A – Assessment
  - R – Treatment
  - T – Transport

Prolonged Field or Extended Field Care

SAR Medical Technicians may be put in a positon for caring for injured/ill patients for periods of up to 24 hours. In these situations, refer to protocols as a baseline and seek online medical control whenever feasible or available.

- For these situations, the acronym **HITMAN** should be used:
  - **H** – Hydration, hypothermia, hygiene
    - Hydration – PO / IV/ IO / NG Tube (PRN), Urine output should be approx. 1-1.5ml/kg/HR. Starting maintenance IVF – rate should be approx. 125 ml/hr.
    - Hypothermia – Insulate from the ground, keep warm and dry
    - Hygiene – Prevent sores / roll and pad the patient, keep patient clean and dry.
  - **I** – Infection: Monitor compartment syndrome, change dressings 12-24hrs, antibiotics as per protocol.
  - **T** – Tubes: Neat and tight, continue to suction as needed.
  - **M** – Medications: 6 Rights: Patient, med, dose, time, route, documentation.
    - Monitoring Vitals: If stable, q2-4 h. At a minimum no less than q 12h.
  - **A** – Analgesic: Document pain scale, Pain regime per protocol.
  - **N** – Nutrition: If able, 1500 calorie a day intake.
    - Extremely important for all patients that are alert and oriented and can swallow without difficulty and for the SMT caring for the patient. (Tubed or altered mental status patients should not be given food)

If a patient becomes unstable during any extended care, restart back at the MARCH PAWS phase and reassess history once stability is regained.

II. ADMINISTRATIVE

5. Refusal of medical care and/or transport:

In general, Active Duty military members may not refuse life-saving medical care. Mentally competent adult civilians (including dependents, spouses and retired military members) may refuse medical care, even if refusing medical care endangers their lives. SMT's should make every effort to ensure that patients refusing medical care are aware of the possible consequences of their actions. The patient should be urged to seek other medical care as soon as possible.

• If the patient is unconscious, or unable to make a rational decision (secondary to head injury or any other cause of altered mental status) the principle of ***Implied Consent*** assumes that a normal, rational person would consent to life-saving medical treatment.

• If the patient is a minor or mentally incompetent adult, permission to treat must be obtained from a parent or guardian before treatment can be rendered. If a life-threatening condition exists, and the parent or guardian is unavailable for consent, treatment shall be rendered under the principle of implied consent, as noted above.

• If an alert, oriented patient with normal mental status refuses medical care, then care cannot be rendered. Medical control should be contacted (if possible) if such a situation occurs.

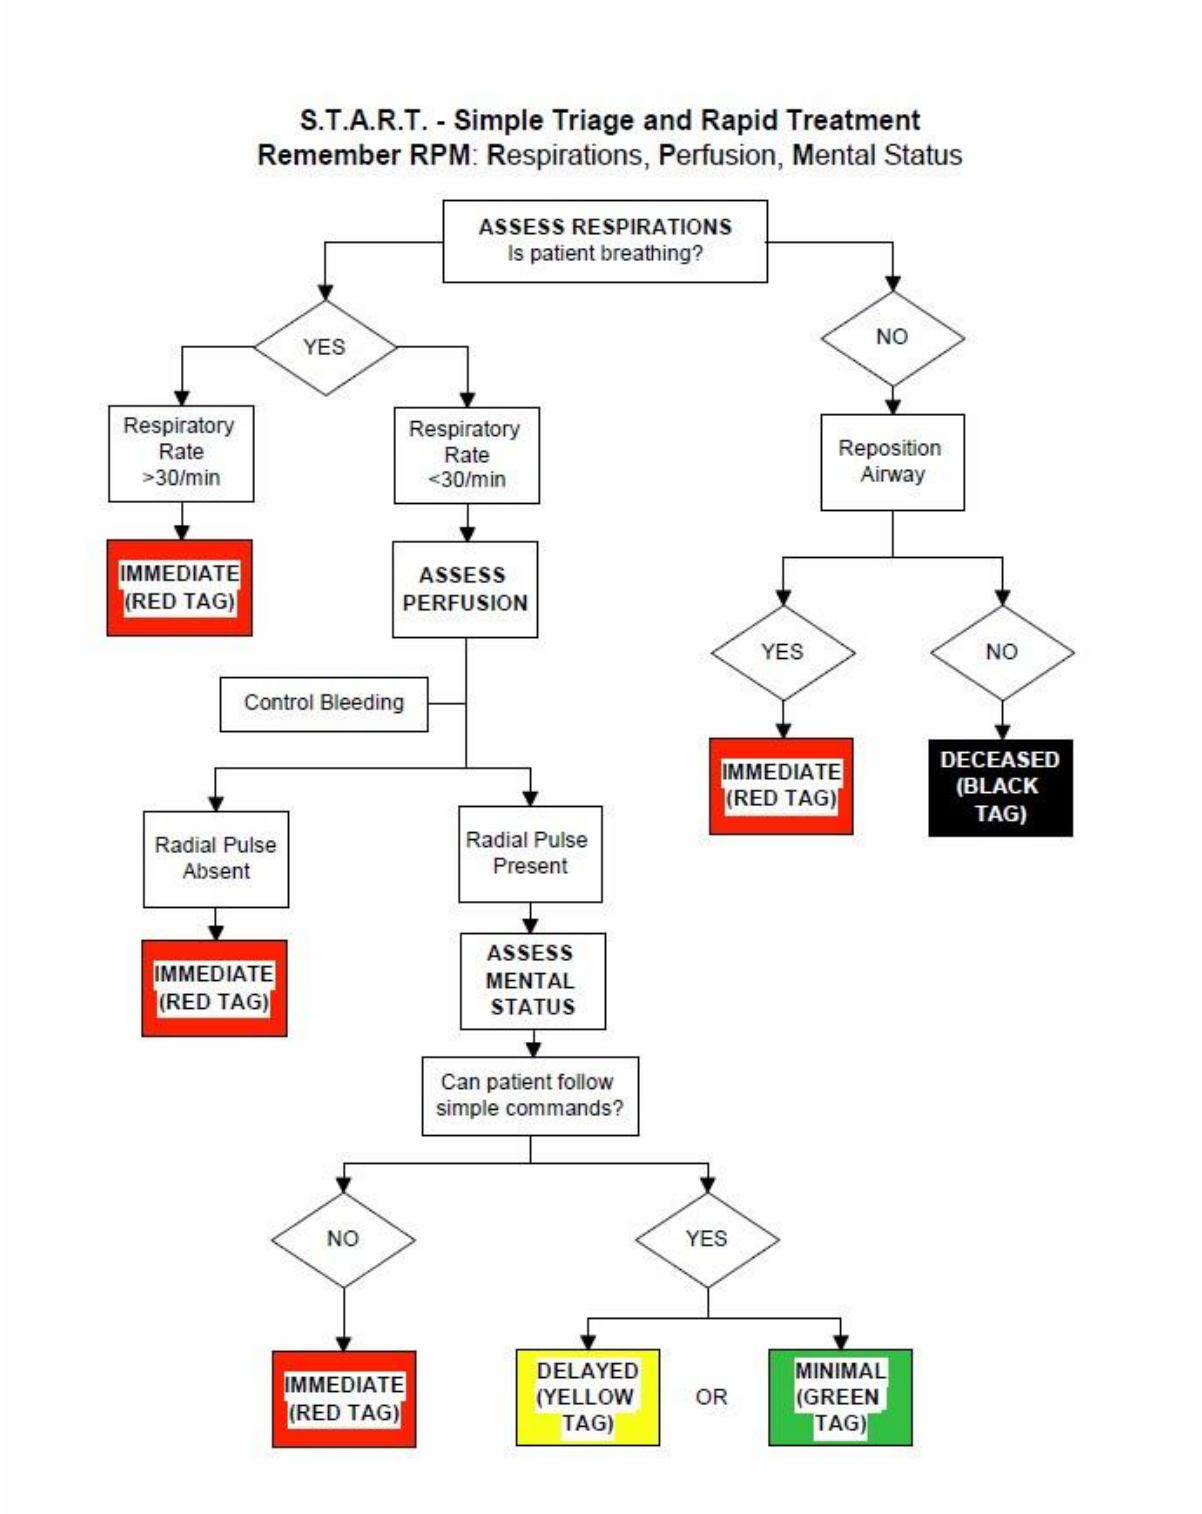
• If a patient refuses medical care the following statement must be written on the medical treatment form and signed by the patient:

"I, THE UNDERSIGNED HAVE BEEN ADVISED THAT MEDICAL ASSISTANCE ON MY BEHALF IS NECESSARY AND THAT REFUSAL OF SAID ASSISTANCE MAY RESULT IN DEATH, PERMANENT INJURY OR IMPERIL MY HEALTH. I REFUSE TO ACCEPT TREATMENT, AND ASSUME ALL RISK AND CONSEQUENCES OF MY DECISION. I RELEASE THE UNITED STATES AIR FORCE AND THE DEPARTMENT OF DEFENSE FROM ANY LIABILITY ARISING FROM MY REFUSAL TO ACCEPT MEDICAL CARE."

- **Note:** The statement must be signed and dated by the patient, and countersigned by a witness. The medical record should completely document that the patient is awake, alert, oriented and has normal mental status. If the patient refuses to sign the form, and still refuses medical care, the patient's refusal to sign should be documented and signed by the treating SMT and preferably by at least one other witness.

II. ADMINISTRATIVE

6. **Triage – S.T.A.R.T Flowchart**



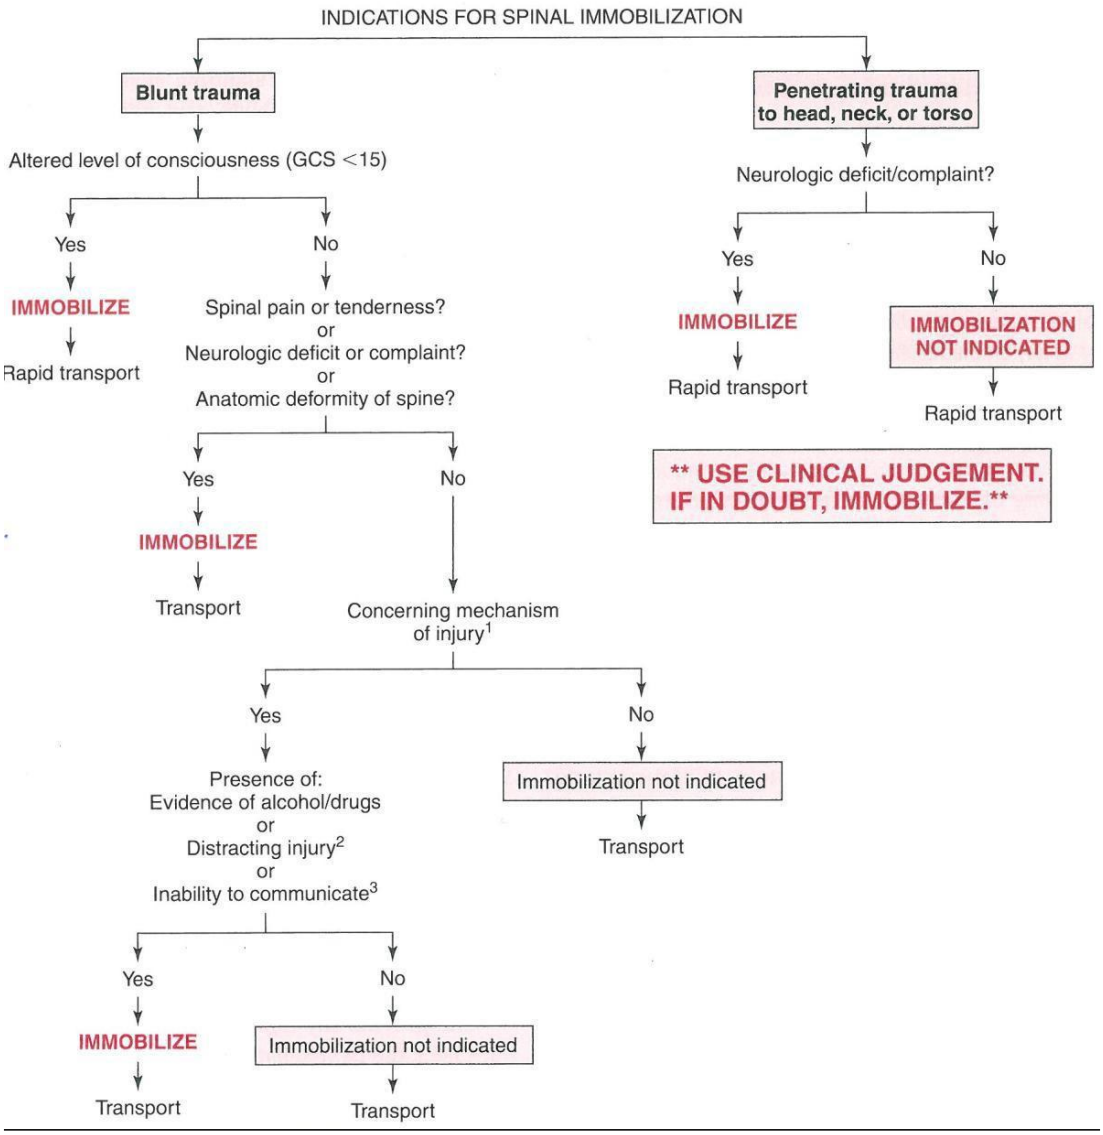
II. ADMINISTRATIVE

7. Spinal Immobilization

Spinal Immobilization is indicated for trauma patients where there is a suspicion of spinal injury or the patient complains of pain associated with the spinal column. Special consideration should be given when the patient age is <8 or >70 years of age.
The provider may decide to forgo spinal immobilization if the following criteria are met:

-No significant mechanism of injury (MOI)
-No loss of consciousness (LOC)
-No altered level of consciousness (LOC)
-Patient is able to communicate and is a reliable historian
-No signs of intoxication
-No distracting injuries
-No midline back or neck pain with or without movement
-No midline pain or tenderness or deformity present in back or neck upon palpation
-No pain present through full range of motion

Risk of spinal immobilization versus benefits should be weighed in special circumstances such as; prolonged extrication from wilderness setting and technical rescue situations. Risks include; emesis with airway compromise, pressure sores, extreme patient discomfort. Index of suspicion for injury should be carefully weighed.



1- Concerning mechanisms of injury

-Any mechanism that produced a violent impact to the head, neck, torso or pelvis
-Incidents producing sudden acceleration, deceleration, or lateral bending forces to the neck or torso (moderate to high speed mva, cars vs pedestrian, explosions, etc.)
-Any fall, especially in elderly patients
-Ejection or fall from any motorized or otherwise-powered vehicle (scooters, skateboards, bicycles, motorcycles, motor vehicles, or recreation vehicles)
-Victims of shallow water diving accidents

2- Distracting Injury

-Any injury that may have the potential to impair the patient's ability to appreciate other injuries, (long bone fractures, visceral injuries, large lacerations, degloving injuries, crush injury, large burns, or any other injury causing acute functional impairment)

3- Inability to communicate

-Any patient who for reasons not specified above cannot clearly communicate so as to actively participate in their assessment (speech or hearing impairment, those who only speak a foreign language, small children, etc.)

8. Altitude Physiology and Patient Transfer

ALTITUDE CONCERNS FOR AEROMEDICAL TRANSFERS:

• **Gas expansion** occurs as altitude above sea level increases. The volume of a gas will roughly double at 18,000' mean sea level (½ sea level atmospheric pressure). This will typically not affect the operational ceiling for the MH-60S during Aeromedical Evacuation operations. Certain conditions and precautions to note:

- **Air embolism / Decompression illness** – This is the only absolute contraindication to transport of patients at altitude. These patients should be transferred at sea level or in an A/C capable of cabin pressurization to sea level.

- **Pneumothorax** – There is little risk of developing a tension PTX due to gas expansion from altitude during typical aeromedical evacuation flights in rotary-wing A/C. However, altitude should be limited when possible to <5,000' MSL. If mission requirements mandate higher altitudes, the use of aeromedical evacuation platforms with pressurized cabins should be considered as applicable and tactically capable. Prophylactic chest tubes (for altitude-related concerns) are recommended for any flights above 10,000' mean sea level.

- **Gastric distention** – Gas expansion does increase the risk of vomiting and, therefore, aspiration. Therefore, all patients with decreased LOC should have an NG / OG tube placed prior to transfer.

- **Head injury** – As with PTX, there is little concern of altitude related elevation of elevated ICP in head injured patients although penetrating intracranial or maxillofacial injuries may set conditions for an entrapped-gas phenomenon with adverse clinical consequences. Any evidence of elevated ICP should result in treatment per guideline. Altitude restrictions do not differ from those listed for PTX. Constant vigilance should be maintained for evidence of elevation of ICP.

- **Eye injury** – Penetrating eye injuries or surgeries may introduce air into the globe. Again, the altitudes obtained for rotary-wing A/C does not pose a risk of elevating the IOP during normal operations.

- **Gas filled equipment** – Medical equipment with gas filled bladders also may suffer from interference at high-altitudes. Primarily, endotracheal tube cuffs should be evaluated at altitude by testing the pressure of the exterior bladder or filled with air. If able, utilize manometer to verify tube pressure. Verify with

supervising physician or flight surgeon before filling endotracheal tube with saline.

• **Flow Rates:** Decreased atmospheric pressure may interfere with IV flow rates and/or pump function. These must be monitored continuously.

• **Invasive Blood Pressure:** Adjust / re-calibrate monitor every 1000' if required based upon monitoring device.

• **Hypothermia:** As altitude increases, the temperature will drop about 3.5° F per 1000 feet. This is further complicated in the H-60 due to rotor-wash, forward air speed, normal lapse rate. Therefore, patients must be protected from hypothermia at all times. This includes use of the Hypothermia Prevention and Management Kit (HPMK), blankets, heaters if available, and closing cabin doors / crew windows during transport.

• **Hypoxia:** Patients are at increased risk of hypoxia during transport at altitude. If transfers are taking place in high-altitude locations, pulse oxygenation should be monitored at all times and the medic / provider should maintain a low threshold for the use of supplemental SpO_2. At no time should the patient's SpO_2 be allowed to go below 92 percent (commercial pulse oximeters read up to 3 percent off, therefore a sat of 91 percent may be seen in a patient who is really at 88 percent.). ***Patients who smoke or have underlying cardiopulmonary disease are at increased risk even at low altitudes.***

• **Dysbarism:** Patients may experience discomfort due to gas expansion in air-filled body spaces (e.g., ears, sinuses, teeth) during ascent. Conversely, patients and aircrew may experience "squeeze" resulting from descent from altitude. These are typically mild during RW transport, however, if severe, altitude should be held and attempts made to alleviate pain and/or slow rate of ascent / descent.

Document procedure, results, and vital signs.

III. ADULT PATIENT CARE PROTOCOLS

1. ***Airway / Oxygenation / Ventilation***

A. Objectives:

1) When possible, a room air pulse oximetry reading should be obtained and documented.

2) The goal is to maintain SP02 > 94%, $EtCO_2$ 35-45mmHg unless suspected Head Trauma.

3) Establish an airway for all patients who cannot maintain their own.

B. Warnings/Alerts:

1) Failure to use end-tidal C02 monitoring increases the risk of an unrecognized misplaced tube. $EtCO_2$ Shall be used in all Post Intubation, Cricothyrotomy, or king/supraglottic airway's.

2) Failure to confirm tube placement prior to securing or following patient movement may lead to unrecognized tube displacement.

3) Apnea is an absolute contraindication to nasal intubation.

4) Unable to open or effectively ventilate the patient with the inability to clear, two failed Supraglottic/ET airway attempts, or intubation is contraindicated shall warrant the performance of a Cricothyroidotomy.

5) All advanced airway patients shall require at a minimum, a c-collar to prevent dislodgement of the airway device.

C. Medications:

1) Post-intubation Sedation:

a) 2-5mg Valium IV or 2mg Versed IV

APPENDIX A : TRAUMA AIRWAY ASSESSMENT

Trauma Airway Management

Airway Assessment

- All trauma airways are potentially high-risk. Anticipate a difficult airway.
- Identify critical team members and verbalize role assignments.
- Initiate pre-oxygenation (1,2).
- Consider Ketamine (0.5-1.0 mg/kg IV/IO) for delayed sequence intubation if combative or otherwise uncooperative patient (3,4,5).
- Recall that the neutral position ("C-spine stabilization") degrades the laryngoscopic view.

Rapid Sequence Induction (RSI) and Intubation Pathway

1. **Confirm equipment availability and function** IV/IO, suction, self-inflating bag and mask, oxygen source, laryngoscope- direct and video (5), ETT with stylet and/or gum elastic bougie, oral & nasal airways, surgical airway kit, drugs, C02 detector, monitors, other rescue equipment
2. **Pre-Oxygenate (Denitrogenate) the lungs (1,2,6)**
   - Prolongs tolerance of apneic period
   - Goal is ≈ 3 minutes of tidal volume breathing at 90% FiO2
   - With standard reservoir facemask set flow rate of oxygen as high as possible
   - Recommend augmenting with nasal cannula at 15L/min oxygen in preparation for apneic oxygenation, leave in situ throughout procedure (2,8)
   - Elevate head of bed if not contraindicated
3. **Maintain cervical spine stabilization**
4. **Remove front of cervical collar**
5. **Consider cricoid pressure simultaneous w/ medication administration (9,10)**
6. **Administer medications** : Initiate RSI

Sedative/hypnotic
- Ketamine (First Line): 2 mg/kg IV/IO
- Etomidate (Second Line): 0.3 mg/kg IV/IO

Unstable patients require reduced dosage of induction agent.

Neuromuscular Blockade
- Rocuronium: 1.2 mg/kg IV/IO or
- Vecuronium: 0.1 mg/kg IV/IO or
- Succinylcholine: 1.5 mg/kg IV/IO

7. **Perform laryngoscopic tracheal intubation**
   - Following onset of neuromuscular blockade
   - Recommend gum elastic bougie as primary ETT stylet
8. **If laryngoscopic view is poor:**
   - Apply external laryngeal manipulation technique(s)
   - Consider alternative visualization method or Supraglottic airway device
9. **Confirm tracheal intubation**
   - Visualize tube passing between the vocal cords (First Line)
   - Wave form or digital capnography when available (Second Line)
   - Easy chest rise, equal axillary breath sounds/absence of gastric insufflation, CO2 Calorimeter, and "fog" in ETT
   - Esophageal detector bulb or fiber optic confirmation during cardiac arrest
10. **Provide continuing care IAW Anesthesia CPG**

Recommendations for Pediatric Patients

1. Train to expect pediatric patients. Have a dedicated pediatric airway cart, including Broselow tape or equivalent.
2. Pre-dose with atropine IV/IO (0.02mg/kg, minimum dose 0.1mg, maximum dose 0.5mg) in all <1 years old, those <5 who are receiving succinylcholine, and in all who receive a 2nd dose of succinylcholine
3. Induction -
   - Ketamine (first line) 2mg/kg IV/IO
   - Etomidate (second line) 0.3mg/kg IV/IO
4. Neuromuscular blockade -
   - Succinylcholine 1.5mg/kg IV/IO (2mg/kg <5 years old) or
   - Rocuronium 1mg/kg IV/IO
5. Avoid surgical airway in <12 years old - use needle cricothyroidotomy (12-14 gauge), tracheostomy preferred over surgical cricothyroidotomy

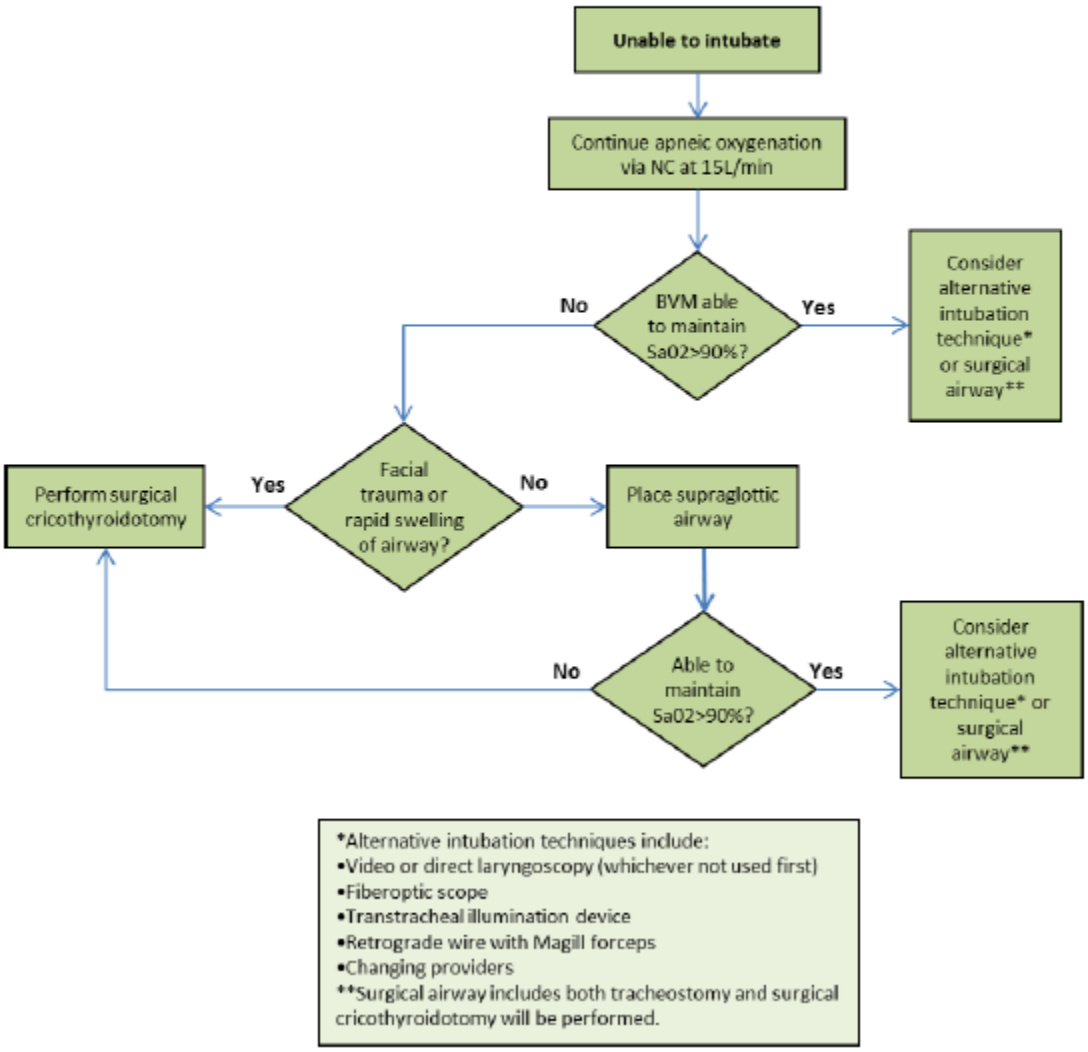
Unable to Intubate: Can You Mask Ventilate?

Mask Ventilation Pearls
- Skilled operator
- Good seal
- Jaw thrust
- Oral airway
- Nasal airway(s)
- Two operator mask ventilation

YES
- Improve position, change blade/operator, laryngeal manipulation technique, gum elastic bougie.
- Attempt alternate technique: Fiber optic, video laryngoscope, tracheal trans illumination device.
- More than ≈ 3 attempts at intubation may abolish your ability to mask ventilate due to edema caused by laryngoscopy.
- Surgical airway (Cricothyroidotomy or tracheostomy)

NO
- Emergency pathway...seconds matter.
- Supraglottic airway or
- Surgical cricothyroidotomy

APPENDIX B: DIFFICULT AIRWAY MANAGEMENT ALGORITHM



Unable to intubate
Continue apneic oxygenation via NC at 15L/min
BVM able to maintain Sa02>90%?
No
Yes
Consider alternative intubation technique* or surgical airway**
Facial trauma or rapid swelling of airway?
Yes
No
Perform surgical cricothyroidotomy
Place supraglottic airway
Able to maintain Sa02>90%?
No
Yes
Consider alternative intubation technique* or surgical airway**
*Alternative intubation techniques include:
•Video or direct laryngoscopy (whichever not used first)
•Fiberoptic scope
•Transtracheal illumination device
•Retrograde wire with Magill forceps
•Changing providers
**Surgical airway includes both tracheostomy and surgical cricothyroidotomy will be performed.

III. ADULT PATIENT CARE PROTOCOLS

2. ***Allergic / Anaphylactic Reaction***

A. Objectives:

1) To assess and appropriately treat patients with allergic reaction and/or anaphylaxis.

2) To differentiate between an allergic reaction and anaphylaxis.

B. General Information:

1) Rapidly progressing signs and symptoms shall be treated as anaphylaxis.

2) RS or RS-EMT's may use patients EPI-Pen or EPI-Pen from Med Kit.

3) In severe anaphylaxis with hypotension and/or severe airway obstruction, medical control may order Epinephrine 1: 10,000 IV.

4) Solu-Medrol should not be routinely administered to pediatric patients, however may be considered by medical control for extended transports.

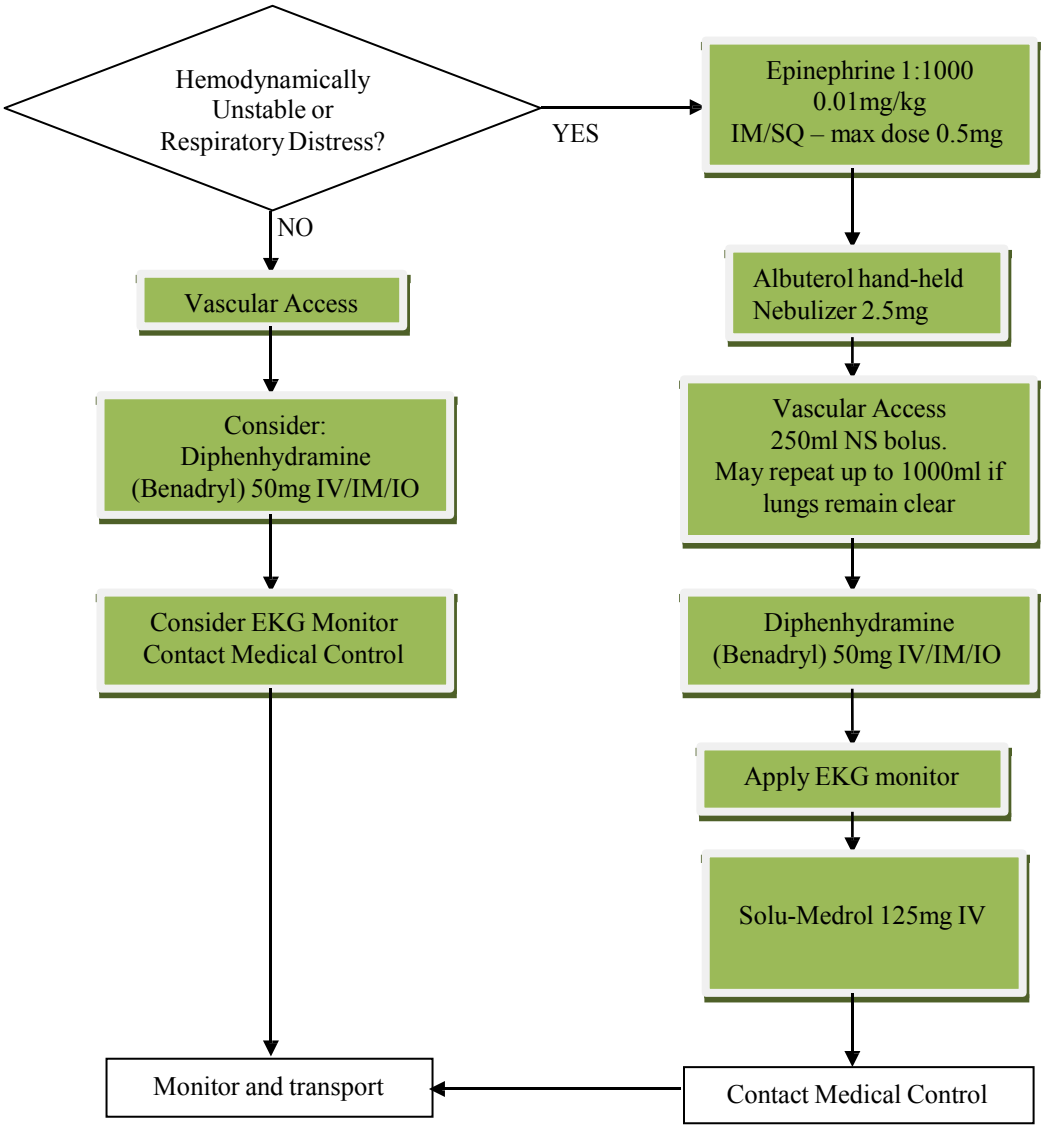
C. Warnings/Alerts:

1) Epinephrine 1:1000 shall not be given IV.

2) Contact medical control before administering Epinephrine to patients with cardiac HX or 40 years or older.

3) Maximum dose of Epinephrine 1:1000 is 0.5mg.

Allergic / Anaphylactic Reaction



Hemodynamically Unstable or Respiratory Distress?
YES
NO
Epinephrine 1:1000 0.01mg/kg IM/SQ – max dose 0.5mg
Albuterol hand-held Nebulizer 2.5mg
Vascular Access 250ml NS bolus. May repeat up to 1000ml if lungs remain clear
Diphenhydramine (Benadryl) 50mg IV/IM/IO
Apply EKG monitor
Solu-Medrol 125mg IV
Contact Medical Control
Vascular Access
Consider: Diphenhydramine (Benadryl) 50mg IV/IM/IO
Consider EKG Monitor Contact Medical Control
Monitor and transport

III. ADULT PATIENT CARE PROTOCOLS

3. Altered Mental Status / Syncope

A. Objective:

1) To appropriately assess and treat patients with Altered Mental Status / Syncope

B. General Information:

1) Consider alternate causes using AEIOU-TIPS:
- Alcohol / Acidosis
- Epilepsy
- Insulin
- Overdose
- Uremia / Renal Failure
- Trauma
- Infection
- Psychosis
- Seizures

2) Rechecking glucose after all interventions.

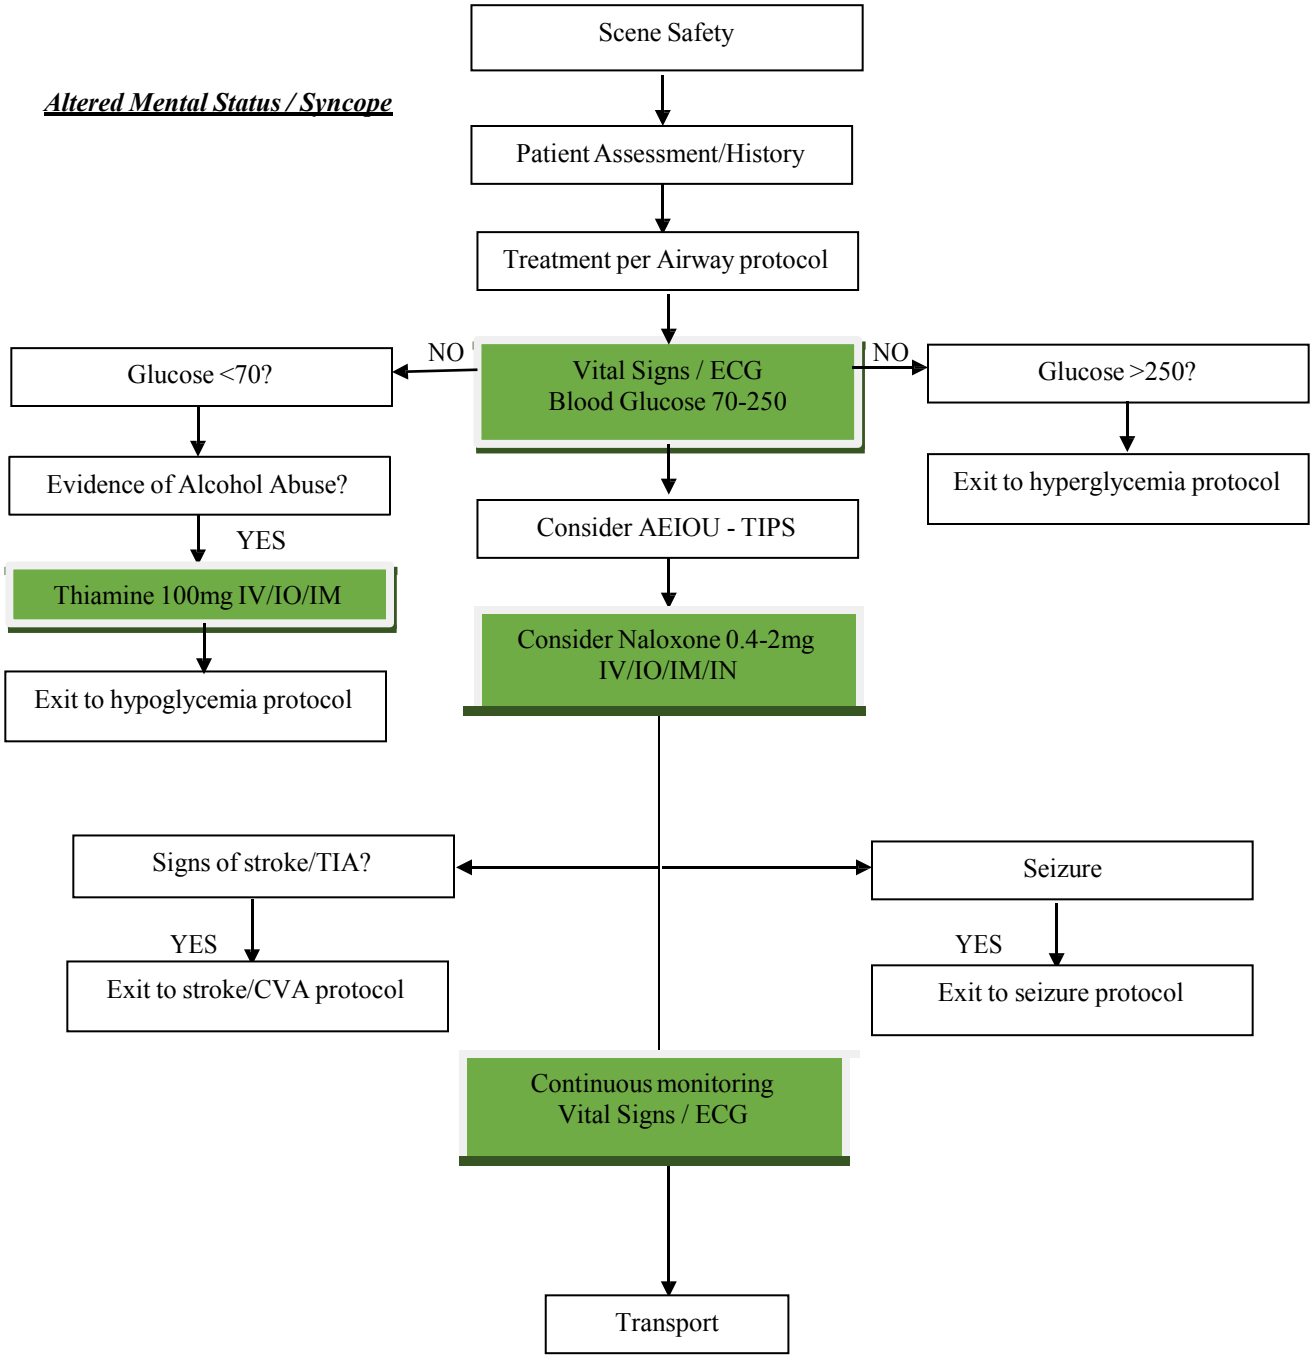
3) Assess for signs of trauma in any syncopal event.

4) EKG monitoring should be obtained in all suspected toxin or diabetic ketoacidosis events.

C. Warnings/Alerts:

1) Be aware of AMS as a presentation of environmental exposure, toxins, and hazmat. Use proper PPE and Decontamination procedures as appropriate.

Altered Mental Status / Syncope



III. ADULT PATIENT CARE PROTOCOLS

4. Altitude Medical Emergencies

D. Objective:

1) To appropriately assess and treat patients with Altitude Illness.

2) Descend to safe appropriate altitude and if symptoms do not resolve, begin treatment.

E. General Information:

1) Acute Mountain Sickness (AMS): Usually occurs at altitudes 8,000ft and higher. Symptoms can occur as quickly as 3 hours after ascent. Signs and symptoms are generally benign and self-limiting, but can become debilitating. Anorexia, nausea, vomiting, insomnia, dizziness, lassitude, and or fatigue.

2) High Altitude Pulmonary Edema (HAPE): Caused by hypoxia of altitude. HAPE is the most common cause of death at altitude. Usually occurs above 8,000ft. Respiratory distress at altitude is HAPE until proven otherwise. Hallmark sign is dyspnea at rest. Other symptoms may include cough, crackles upon auscultation, tachypnea, tachycardia, fever, or low SpO_2 sat disproportionate to elevation.

3) High Altitude Cerebral Edema (HACE): Rare below 11,500ft. Headache is common at altitude and not always associated with HACE. Ataxia and altered mental status at altitude are HACE until proven otherwise. Symptoms include unsteady, wide unbalanced gait and AMS.

F. Warnings/Alerts:

1) HAPE and HACE may coexist in the same patient. If suspected, treat both
2) HAPE and HACE should prompt emergent evacuation and descent
3) Individuals with HACE should not be left alone or allowed to descend alone
4) GAMOW Bag treatment is not a substitute for descent.
5) Minimize patient exertion during descent since this will exacerbate symptoms

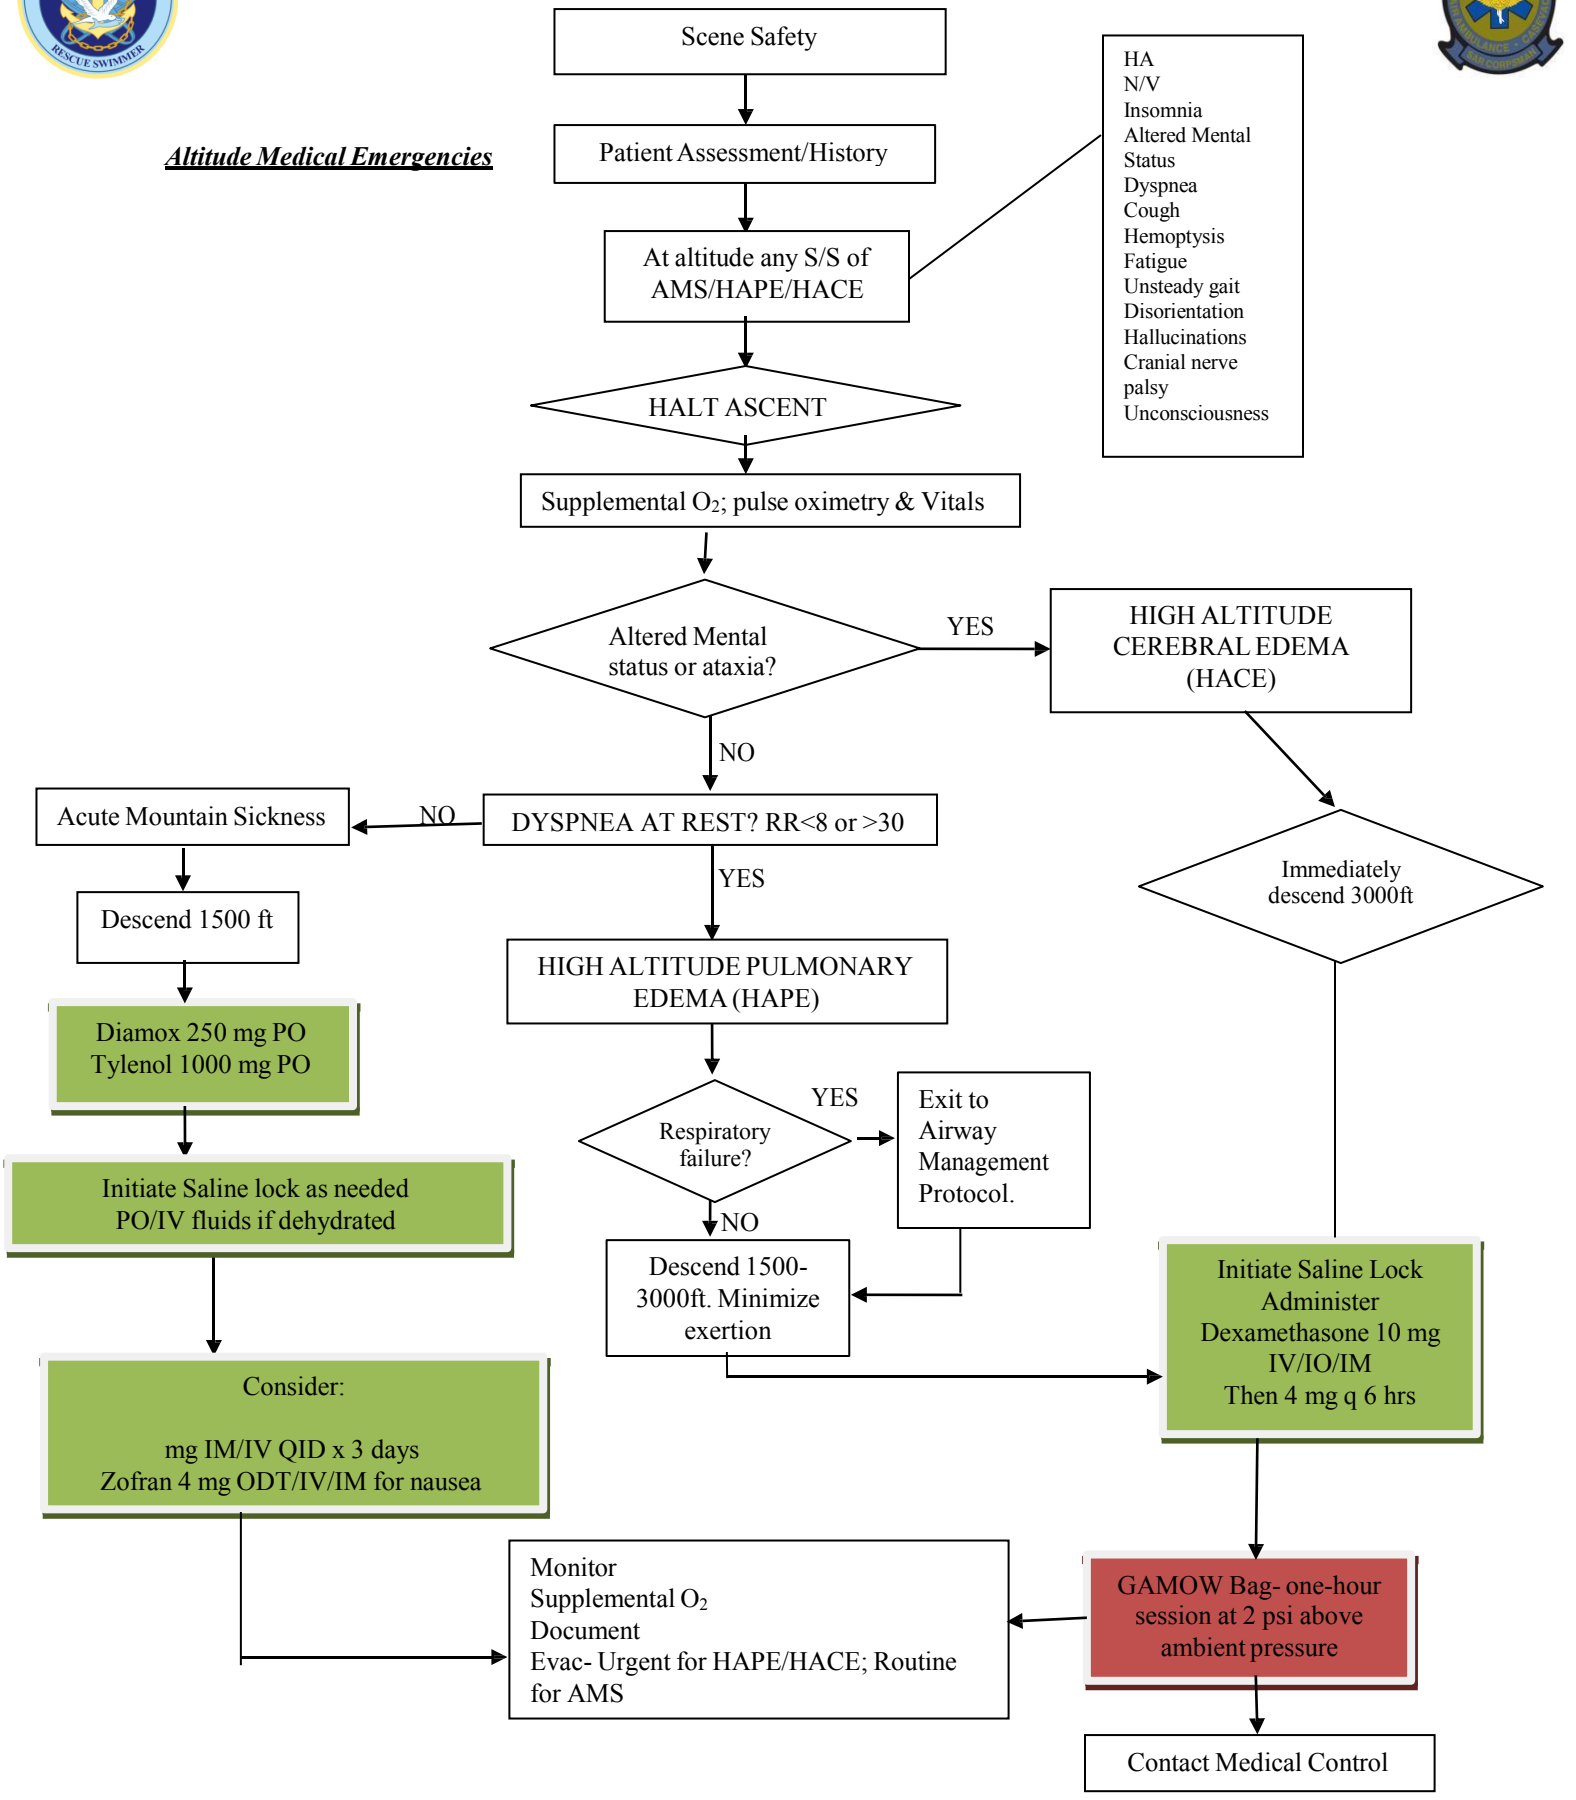
G. Medications/Treatments:

1) Diamox (Acetazolamide)- FOR AMS- 250 mg PO BID; contraindicated in patients with allergy to sulfa

2) Dexamethasone (Decadron)- FOR AMS- 4 mg PO q 6 hours (do not ascend until patient asymptomatic for 24 hours after administration); FOR HAPE/HACE- 10 mg IV/IO/IM STAT, then 4 mg IV/IO/IM q 6 hours

3) GAMOW Bag- One-hour session with bag inflated to 2 PSI above ambient pressure (approx.100 mmHg); repeat four to five times if tactically feasible

Altitude Medical Emergencies



III. ADULT PATIENT CARE PROTOCOLS

5. Bites and Stings

A. Objectives:

1) To appropriately assess and treat patients who receive bites and stings.

2) To identify source of bite and sting.

B. General Information:

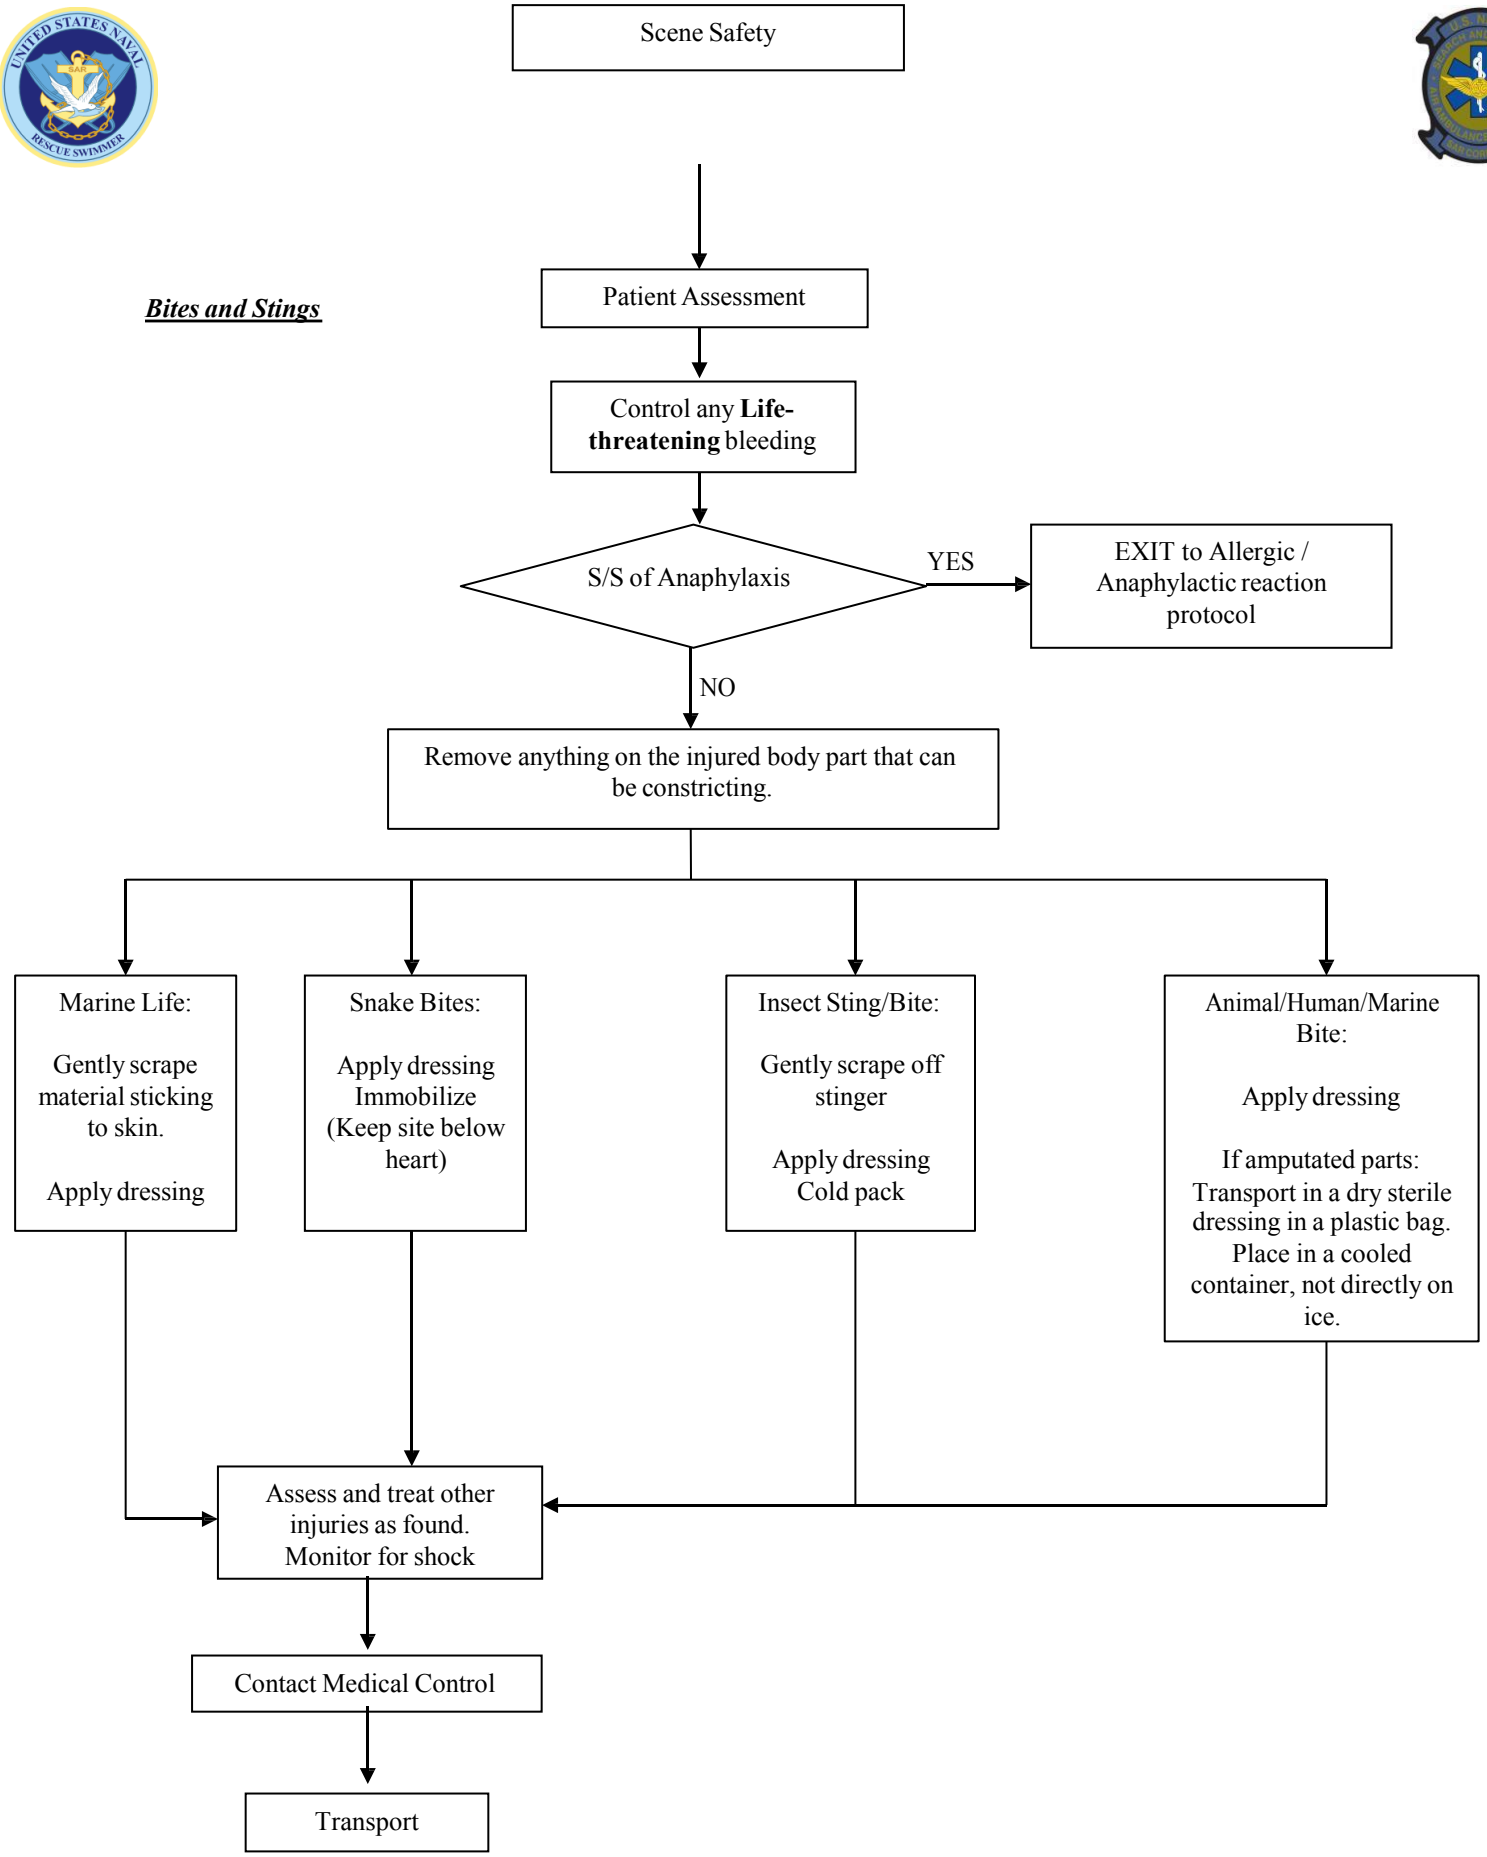
1) The use of constriction bands requires an order from Medical Control.

C. Warnings/Alerts:

1) Make no attempt to capture or kill the animal or insect that inflicted the bite or sting.

2) Shall not transport live animals in the Aircraft. Crew should consider extreme caution in transporting dead animal or consider taking picture of the animal to show Medical Control.

Bites and Stings



III. ADULT PATIENT CARE PROTOCOLS

6. Blood Component / Fresh Whole Blood Use:

A. Objectives:

1) Administration of Blood Components and Whole Blood as per JTS CPG's and DOD TCCC Protocols.

2) Calcium shall be pushed on all patients in hypovolemic shock, requiring blood products, or suspected trauma. 1gm Calcium slow IV/IO push via patent line.

IMMEDIATE CLINICAL INDICATIONS in trauma patients with SERIOUS INJURIES and evidence of hemorrhage / shock:

- Systolic blood pressure less than 100 mm Hg or absence of radial pulse
- Tachycardia greater than 100 beats per minute (BPM) or higher
- Double, triple, or quadruple amputation

CLINICAL INDICATIONS:

- Uncontrolled hemorrhage or evidence of hemorrhagic shock
  - Trauma patients with amputation (complete or partial with distal circulation compromise)
  - Non-compressible penetrating thoracic, abdominal, and transitional zone injuries (axilla, inguinal, neck)
  - Pelvic Fractures in conjunction with traumatic injury (significant mechanism of injury)
  - Clinical signs of coagulopathy
    - Tachycardia, tachypnea, fever, altered mentation, hypoxemia
  - Severe hypothermia associated with blood loss

CONTRAINIDICATIONS:

- None

PRIOR TO BLOOD PRODUCT TRANSFUSION:

- Maximal hemorrhage control
- Treatment of suspected tension pneumothorax
  - Clinical signs may include: hypotension, hypo-perfusion, diminished or absent breath sounds. Late signs include: tracheal deviation and distended neck veins.
- Patent airway or airway control
- IV/IO access
- Hypothermia prevented and/or treated

Blood Component / Fresh Whole Blood Use:

PROCEDURE:

- Document all items on the SF 518 (only authorized document for blood products aboard Army Aeromedical Evacuation platforms.
    - Two person verification of patient and blood products given matching SF 518.
- Observe units of blood
    - Look for gas, discoloration, clots, and sediment
    - Safe-T-Vue must remain white on color indicator. Red coloration indicates that temperature has been exceeded and is no longer acceptable for use.
- Initiate large bore IV (18G min, 14G preferred) or IO access.
    - IO access via sternum or humerus is preferred. Tibia site can be utilized as secondary, but attempt should be made to gain another access point.
    - Lidocaine 2% (2-3 mL) flush in IO sites provides analgesia and increases compliance.
- All blood and blood products will be administered through a dedicated line of NS using Y-tubing with filter.
- Transfuse blood through an approved fluid warming device if available.
- Rapid transfusion can be achieved by using an approved pressure infusion device.
    - Inflate pressure bag to at least 300 mmHg
    - 60 ml syringe or manual pressure can also be utilized in the event a pressure infuser is not available.
- Slow all other concurrent infusions unless they are TXA or RFVIIa.
- Continue resuscitation until palpable radial pulse, improved mental status or SBP of 70-80 mmHg and MAP >60 mmHg.
- Monitor patient every 5 minutes and document any patient signs and symptoms consistent with a transfusion reaction. These include: chills, back or chest pain, rash, fever, hives and/ or wheezing.

Document procedure, results, and vital signs of the SF 518.

CLINICAL PEARLS AND CONSIDERATIONS:

- Febrile Reaction- Temperature increase (1°C or 2°F) from baseline, chills, flushing, headache and rapid pulse
- Allergic/Anaphylaxis Reaction- itching, chills, flushing, nausea/vomiting, coughing and/or wheezing, or laryngeal edema
    - Treat with Diphenhydramine 50mg IVP or IM. Have epinephrine standing by.
- Acute Hemolytic Reaction- rapid onset of dyspnea, hypotension, hemoglobinuria, rise in venous pressure, distended neck veins, cough and/or crackles at the bases of

Blood Component / Fresh Whole Blood Use:

the lungs. Treatment is to stop the transfusion, titrate O2 saturations above 94%, and increase IV fluid hydration to 100-200mL/hr to support a urine output above 100-200mL/hr.

- Circulatory Overload- onset of shortness of breath, tachycardia, hypertension, jugular vein distention, pulmonary rates, and hypoxia. This condition may be difficult to distinguish from a hemolytic reaction.
- If a casualty with an altered mental status due to suspected TBI has a weak or absent peripheral pulse, resuscitate as necessary to restore and maintain a normal radial pulse. If BP monitoring is available, maintain a target systolic BP of at least 70 mmHg.

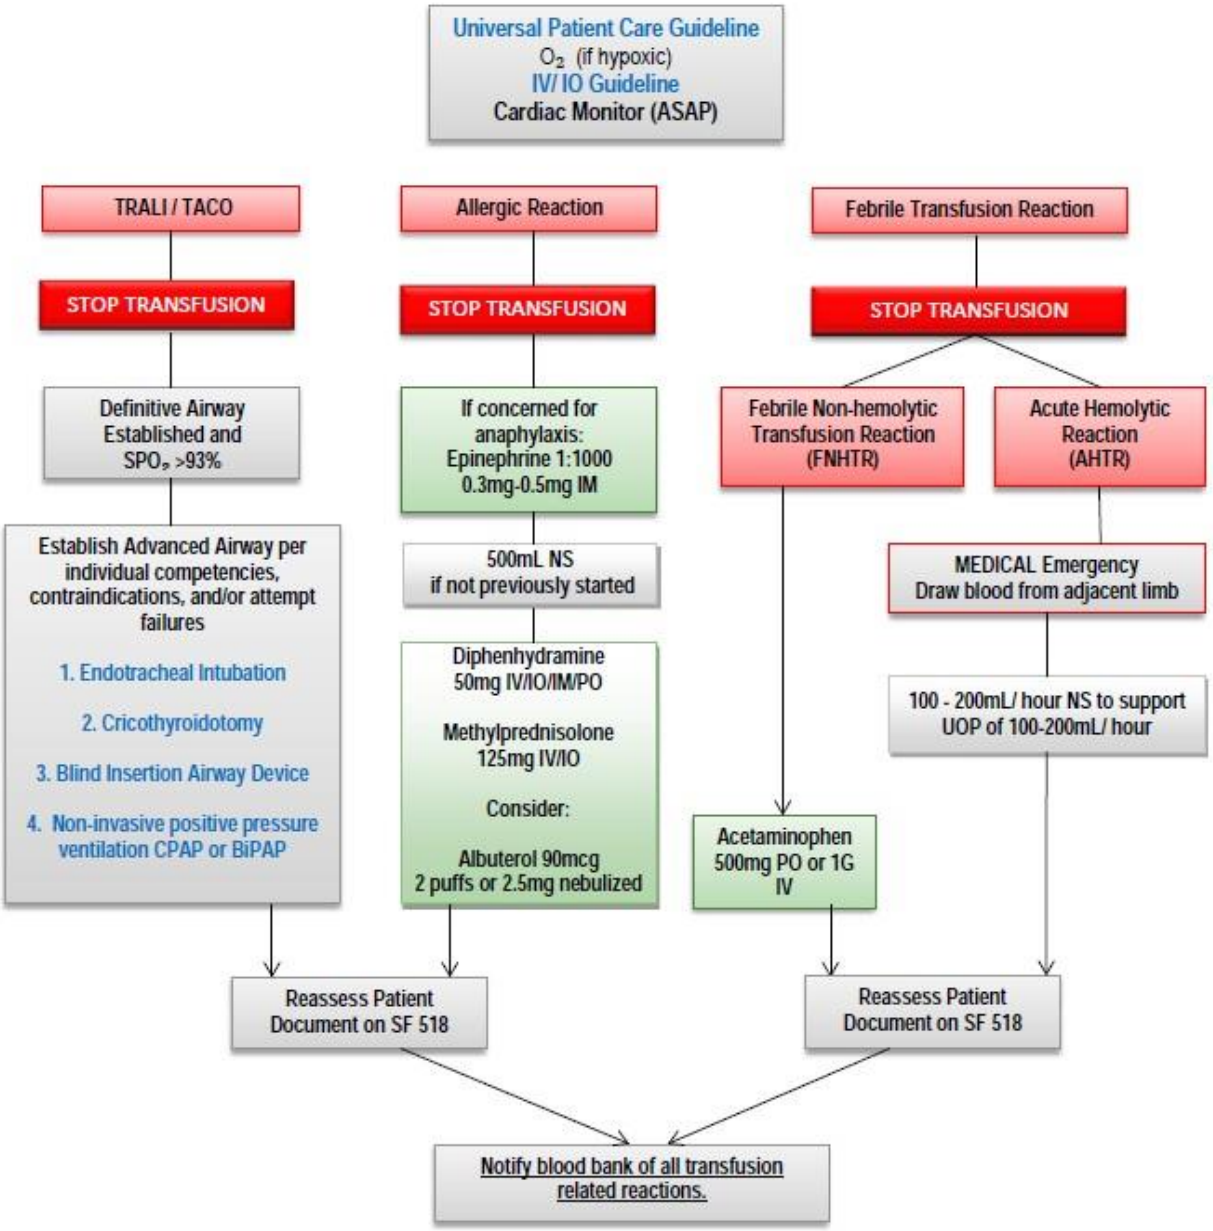
*** Blood component therapy is location specific and is not standard for all missions OCONUS and CONUS. Whole Blood not FDA approved will not be utilized on MEDEVAC air craft unless otherwise specified by area policy or Joint/Army Blood Program.

Differential Diagnosis:	Signs and Symptoms:
Febrile non-hemolytic transfusion reaction (FNHTR)	Fever (>100.4°F) increase of 1°C or 2°F from baseline, chills, possible dyspnea
Acute hemolytic transfusion reaction (AHTR)	Fever (>100.4°F), chills, flank pain, red/brown urine
Anaphylaxis reaction	Rapid onset of shock, hypotension (<100mmHg systolic), angioedema, and respiratory distress
Transfusion-transmitted bacterial infection	Fever (>102.2°F or >3.6°F change after transfusion), rigors, tachycardia (>120 bpm or >40 bpm following transfusion), rise or fall of systolic blood pressure (>30mmHg)
Mechanical-caused hemolysis	Varies with each device. Fever (>100.4°F), chills, possible dyspnea
Transfusional volume/circulatory overload (TACO)	Dyspnea, orthopnea, tachycardia (>100 bpm), wide pulse pressure, hypertension (>140mmHg systolic), hypoxemia (SPO2 <94%), headache, possible seizure
Transfusion-related acute lung injury (TRALI)	Hypoxemia (SPO2 <94%), Fever (>100.4°F), hypotension (<100mmHg systolic), cyanosis, tachypnea (>24 breaths per minute), tachycardia (>100 bpm)

Pearls:

- GENERAL RULES:
  - Stop the transfusion
  - Keep the intravenous line open with saline
  - Identify and treat cause of the reaction
  - Re-institute the transfusion only if it is deemed to be clinically essential
- Before initiating IVF bolus, ensure IV tubing is new. DO NOT USE existing Y-tubing from blood administration set.
- The most common transfusion reaction is a febrile, non-hemolytic transfusion reaction. These are mostly benign with no lasting sequelae. Treatment consists of antipyretics. (Acetaminophen 500mg PO every 4 hours or 1 Gram IV every 6 hours.)
- TRALI is the leading cause of transfusion-related mortality and commonly occurs is patients who have undergone recent surgery, massive blood transfusion, or who have an active infection. Goal of treatment is supportive and aimed at maintaining oxygenation and reducing respiratory distress.
- TACO is essentially pulmonary edema secondary to congestive heart failure usually occurring in elderly, small children and those with compromised cardiac function. Large volumes of fluid given rapidly are a common precursor to this reaction. Goal is aimed at mobilizing fluids (diuretics) and treating underlying condition. Both TACO and TRALI require immediate resuscitation by an advanced level practitioner.
  - A unit of packed cells should be given at a rate of 2.5-3.0 mL/kg per hour.
- Mechanical-caused hemolysis is commonly caused by rapid transfusion, poor collection and storage, or heating the blood above 42°C during transfusion.

Blood Component / Fresh Whole Blood Use:



Universal Patient Care Guideline
O_2 (if hypoxic)
IV/ IO Guideline
Cardiac Monitor (ASAP)

1. Endotracheal Intubation
2. Cricothyroidotomy
3. Blind Insertion Airway Device
4. Non-invasive positive pressure ventilation CPAP or BiPAP
Allergic Reaction
STOP TRANSFUSION
If concerned for anaphylaxis: Epinephrine 1:1000 0.3mg-0.5mg IM
500mL NS if not previously started
Diphenhydramine 50mg IV/IO/IM/PO
Methylprednisolone 125mg IV/IO
Consider:
Albuterol 90mcg 2 puffs or 2.5mg nebulized
Febrile Transfusion Reaction
STOP TRANSFUSION
Febrile Non-hemolytic Transfusion Reaction (FNHTR)
Acetaminophen 500mg PO or 1G IV
Acute Hemolytic Reaction (AHTR)
MEDICAL Emergency Draw blood from adjacent limb
100 - 200mL/ hour NS to support UOP of 100-200mL/ hour
Reassess Patient Document on SF 518
Reassess Patient Document on SF 518
Notify blood bank of all transfusion related reactions.

Pearls:

- Blood transfusions conducted during point of injury for casualties suffering from blood loss/massive hemorrhage may not show any transfusion reaction during the limited transport time.

III. ADULT PATIENT CARE PROTOCOLS

7. *Breathing Difficulty:*

A. Objectives:

1) To assess and treat patients with breathing difficulty.

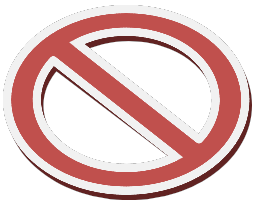
2) To determine the most likely cause of the patients breathing difficulty.

B. General Information:

1) A patient with a HX of CHF that has wheezing upon auscultation of lung sounds should not be automatically classified as asthma / COPD patient.

2) Congestive Heart Failure (CHF) is primarily a cardiac event, not a respiratory event. Treatment should be focused on reducing preload and after load. CPAP or aggressive BVM treatment is an appropriate first line treatment. Patients in end stage renal failure should get Medical Control orders before the administration of Lasix.

3) Bronchoconstriction (Asthma, COPD) patients in severe distress may receive Albuterol 2.5mg/ Atrovent 0.5mg duo Nebulizer as first line treatment. Atrovent shall only be used once.
For severe asthma Medical control may order:
- Epinephrine 1:1,000 0.01mg/kg IM, max dose of 0.5mg



C. Warnings/Alerts:

1) Do not administer Epinephrine 1:1,000 IV/IO

2) Do not administer Nitroglycerin to patients that have taken PDE inhibitors in the past 72 hours.

3) CPAP may worsen existing hypotension.

4) Patients must be conscious with regular respirations for CPAP to be effective.

5) Consider spontaneous pneumothorax vs. tension, monitor closely for s/s of shock.

III. ADULT PATIENT CARE PROTOCOLS

8. ***Burns***

A. Objectives:

1) To assess and appropriately treat patients with burn injuries.

2) To determine the extent and severity of burn injuries.

B. General Information:

1) Stop the burning process.

2) Remove affected clothing, if clothing is stuck to skin cut the clothing instead of pulling it away.

3) Burned areas shall be covered with dry sterile dressings.

4) Parkland formula for IV Fluid Replacement

$$\underline{2ml \times BSAB \times weight = total\ fluid\ in\ ml}$$

Give this amount over first 8 hrs from time of injury, then equal amount over the next 16 hours

5) Urinary Output is the MOST reliable guide in predicting adequate resuscitation:
Adult: 0.5ml per kg per hour (100ml/hr for Electrical Burns)
Children: <40kg: 1ml/kg/hr

C. Warnings/Alerts:

1) Do not delay transport to start IV's or perform other non-life saving ALS interventions.

2) In mass casualty situations from Lighting Strikes, reverse triage should be performed (I.E. those in cardiac arrest should be resuscitated first). Ventricular fibrillation and asystole are the most common dysrhythmias.

3) Inhalation burns with impending airway compromise should be treated with aggressive airway management. Burns with >40%, will likely require RSI due to airway edema from inflammation/fluid resuscitation.

4) Burn patients are prone to hypothermia and shall be protected from the environment. Avoid using ice to cool "large" affected areas.

5) Never use nitrates for suspected Cyanide toxicity in enclosed space fires, it can worsen hypoxia. If a suspected cyanide toxicity, consider use of hydroxcobalmin (CYANOKIT)

Burns

Patient Assessment

↓

Treatment per Airway protocol

↓

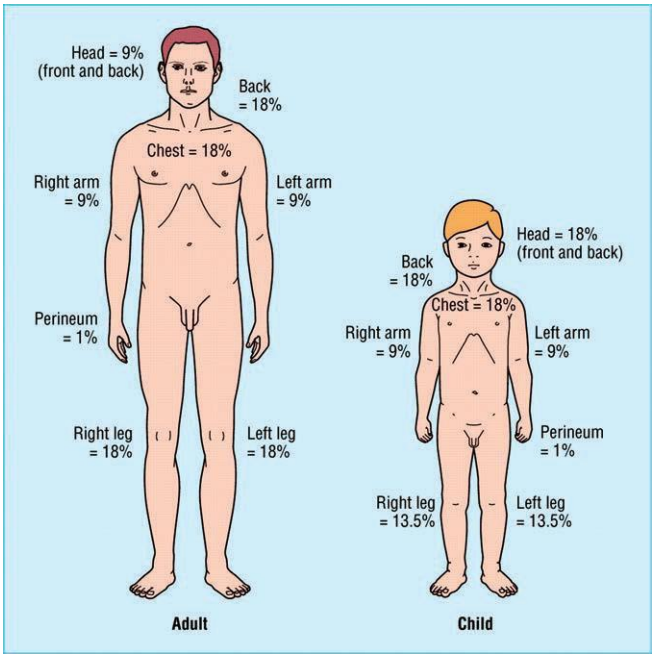
Stop the burning process

↓

Consider aggressive airway management for inhalation injury

↓

Estimate body surface burned



↓

Monitor
Prevent and
Treat for Hypothermia

↔

All Electric burns or possible electrocutions require EKG Monitoring.

↓

Vascular Access
2ml X BSAB x weight = total fluid in ml

↓

Pain medications per Pain Protocols

↔

Transport to burn center or Level 1 trauma center as appropriate.

III. ADULT PATIENT CARE PROTOCOLS

9. *Cerebral Vascular Accident*

A. Objectives:

1) To assess and appropriately treat patients with suspected CVA or Stroke.

B) General Information:

1) Obtain specific history:
- Onset of stroke symptoms
- List of signs/symptoms
- Previous CVA?
- New onset dysrhythmias

2) From time of first signs and symptoms to advance level of care, timeline of transport should be under 90 minutes.

3) Cincinnati Prehospital Stroke Scale is preferred method of prehospital determination. In the event that the assessment of the patient is done in the aircraft, the Los Angeles Pre-Hospital Stroke Screen (LAPSS) should be done.

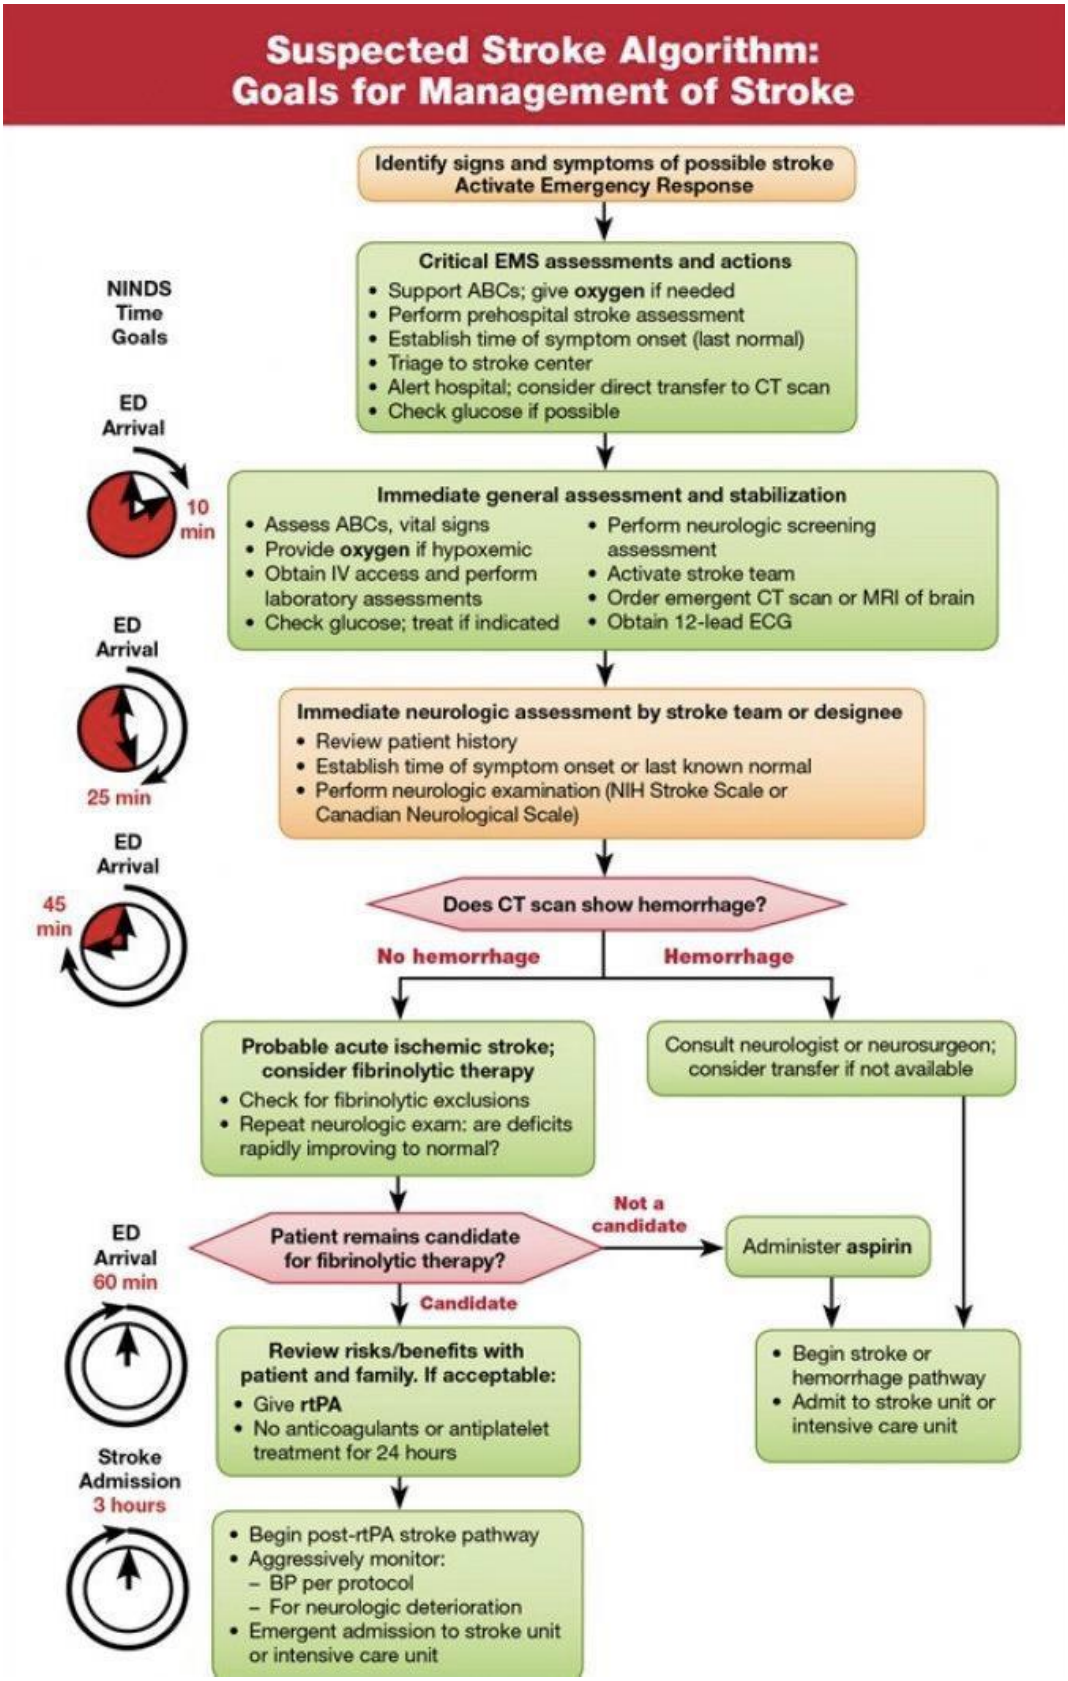
4) Using the Cincinnati Scale, if any of the screening questions are answered yes and the exam is positive for any one Stroke signs and symptoms then the patient should be treated as a Cerebral Vascular Accident. Information shall be relayed to the appropriate next level of care to relay the Cincinnati Stroke Scale results.

C. Warnings/Alerts:

1) Do not delay transport to start IV's or perform other non-life-saving ALS interventions.

2) Patients with stroke symptoms are at high risk for airway compromise.

3) Hypoxemia will worsen stroke outcomes.



Suspected Stroke Algorithm:
Goals for Management of Stroke
Identify signs and symptoms of possible stroke
Activate Emergency Response
NINDS Time Goals
Critical EMS assessments and actions
• Support ABCs; give oxygen if needed
• Perform prehospital stroke assessment
• Establish time of symptom onset (last normal)
• Triage to stroke center
• Alert hospital; consider direct transfer to CT scan
• Check glucose if possible
ED Arrival
10 min
Immediate general assessment and stabilization
• Assess ABCs, vital signs
• Provide oxygen if hypoxemic
• Obtain IV access and perform laboratory assessments
• Check glucose; treat if indicated
• Perform neurologic screening assessment
• Activate stroke team
• Order emergent CT scan or MRI of brain
• Obtain 12-lead ECG
ED Arrival
25 min
Immediate neurologic assessment by stroke team or designee
• Review patient history
• Establish time of symptom onset or last known normal
• Perform neurologic examination (NIH Stroke Scale or Canadian Neurological Scale)
ED Arrival
45 min
Does CT scan show hemorrhage?
No hemorrhage
Hemorrhage
Probable acute ischemic stroke; consider fibrinolytic therapy
• Check for fibrinolytic exclusions
• Repeat neurologic exam: are deficits rapidly improving to normal?
Consult neurologist or neurosurgeon; consider transfer if not available
ED Arrival 60 min
Patient remains candidate for fibrinolytic therapy?
Not a candidate
Administer aspirin
Candidate
Review risks/benefits with patient and family. If acceptable:
• Give rtPA
• No anticoagulants or antiplatelet treatment for 24 hours
• Begin stroke or hemorrhage pathway
• Admit to stroke unit or intensive care unit
Stroke Admission 3 hours
• Begin post-rtPA stroke pathway
• Aggressively monitor:
– BP per protocol
– For neurologic deterioration
• Emergent admission to stroke unit or intensive care unit

Out-of-Hospital Assessment of the Patient With Acute Stroke

- Ensure adequate airway
- Measure vital signs frequently
- Conduct general medical/trauma assessment
  - Trauma of head or neck
  - Cardiovascular abnormalities
  - Check pupils
  - Check glucose level
- Conduct neurologic examination
  - Level of consciousness
  - Cincinnati Prehospital Stroke Scale (+/–)
  - Los Angeles Prehospital Stroke Screen (+/–)
  - Glasgow Coma Scale (score/15)
  - Report right and left limb movements
  - Report meningeal signs (yes/no)
  - Report time of onset of symptoms
  - Report any seizure activity
  - Provide prearrival notification to receiving hospital of potential stroke patient

Glasgow Coma Scale

	Score (maximum = 15)
Eye opening	
Spontaneous	4
In response to speech	3
In response to pain	2
None	1
Best verbal response	
Oriented conversation	5
Confused conversation	4
Inappropriate words	3
Incomprehensible sounds	2
None	1
Best motor response	
Obeys	6
Localizes	5
Withdraws	4
Abnormal flexion	3
Abnormal extension	2
None	1

Interpretation:
Score 14 to 15: Mild dysfunction
Score 11 to 13: Moderate to severe dysfunction
Score 10: Severe dysfunction

The Cincinnati Prehospital Stroke Scale

(Kothari R, et al. *Acad Emerg Med*. 1997;4:986-990.)

Facial Droop (have the patient show teeth or smile):
- Normal—both sides of face move equally
- Abnormal—one side of face does not move as well as the other side

Arm Drift (patient closes eyes and extends both arms straight out, with palms up, for 10 seconds):
- Normal—both arms move the same *or* both arms do not move at all (other findings, such as pronator drift, may be helpful)
- Abnormal—one arm does not move *or* one arm drifts down compared with the other

Abnormal Speech (have the patient say "you can't teach an old dog new tricks"):
- Normal—patient uses correct words with no slurring
- Abnormal—patient slurs words, uses the wrong words, *or* is unable to speak

Interpretation: If any *1* of these 3 signs is abnormal, the probability of a stroke is 72%.

Left: normal. Right: stroke patient with facial droop (right side of face).

Los Angeles Prehospital Stroke Screen (LAPSS)

For *evaluation of acute, noncomatose, nontraumatic neurologic complaint*. If items 1 through 6 are ***all* checked "Yes"** (or "Unknown"), provide prearrival notification to hospital of potential stroke patient. If any item is checked "No," return to appropriate treatment protocol. *Interpretation:* 93% of patients with stroke will have a positive LAPSS score (sensitivity = 93%), and 97% of those with a positive LAPSS score will have a stroke (specificity = 97%). Note that the patient may still be experiencing a stroke if LAPSS criteria are not met.

Criteria	Yes	Unknown	No
1. Age >45 years	❑	❑	❑
2. History of seizures or epilepsy **absent**	❑	❑	❑
3. Symptom duration <24 hours	❑	❑	❑
4. At baseline, patient is **not** wheelchair bound or bedridden	❑	❑	❑
5. Blood glucose between 60 and 400	❑	❑	❑

6. ***Obvious asymmetry*** (right vs left) in ***any*** of the following 3 exam categories **(must be unilateral):**

	Equal	R Weak	L Weak
Facial smile/grimace	❑	❑ Droop	❑ Droop
Grip	❑	❑ Weak grip	❑ Weak grip
		❑ No grip	❑ No grip
Arm strength	❑	❑ Drifts down	❑ Drifts down
		❑ Falls rapidly	❑ Falls rapidly

Kidwell CS, Saver JL, Schubert GB, Eckstein M, Starkman S. Design and retrospective analysis of the Los Angeles prehospital stroke screen (LAPSS). *Prehosp Emerg Care*. 1998;2:267-273.

Kidwell CS, Starkman S, Eckstein M, Weems K, Saver JL. Identifying stroke in the field: prospective validation of the Los Angeles Prehospital Stroke Screen (LAPSS). *Stroke*. 2000;31:71-76.

One-sided motor weakness (right arm).

PAGE INTENTIONALLY

LEFT BLANK

III. ADULT PATIENT CARE PROTOCOLS

10. *Chemical Exposure*

A. Objectives:

1) To assess and treat patients who have been poisoned by various substances.

B. General Information:

1) If the scene is unsafe, do not put your aircraft in an unsafe environment.

2) Dry chemicals shall be brushed off before flushing the skin or eyes with water.

3) Chemical exposure to eyes can be flushed with IV saline.

4) Removed all contaminated clothing.

5) Asphyxiants:
- Examples – Carbon monoxide, cyanide, hydrogen sulfide
- Pulse oximetry may be unreliable due to effect on red blood cells

Cholinergic:
- Examples – Organophosphates, carbamates, military nerve agents

SLUDGE – Salvation, Lacrimation, Urination, Defecation, Gastro cramping, Emesis

Corrosives:
- Examples – Acids and Bases

Do not induce vomiting. Consider aggressive airway management because of mucous membrane swelling.

Hydrocarbons:
- Examples – Gasoline, methane, toluene

Do not induce vomiting.

Irritant Gas:
- Examples – Chlorine, ammonia, phosgene

Aggressive airway management per protocol.

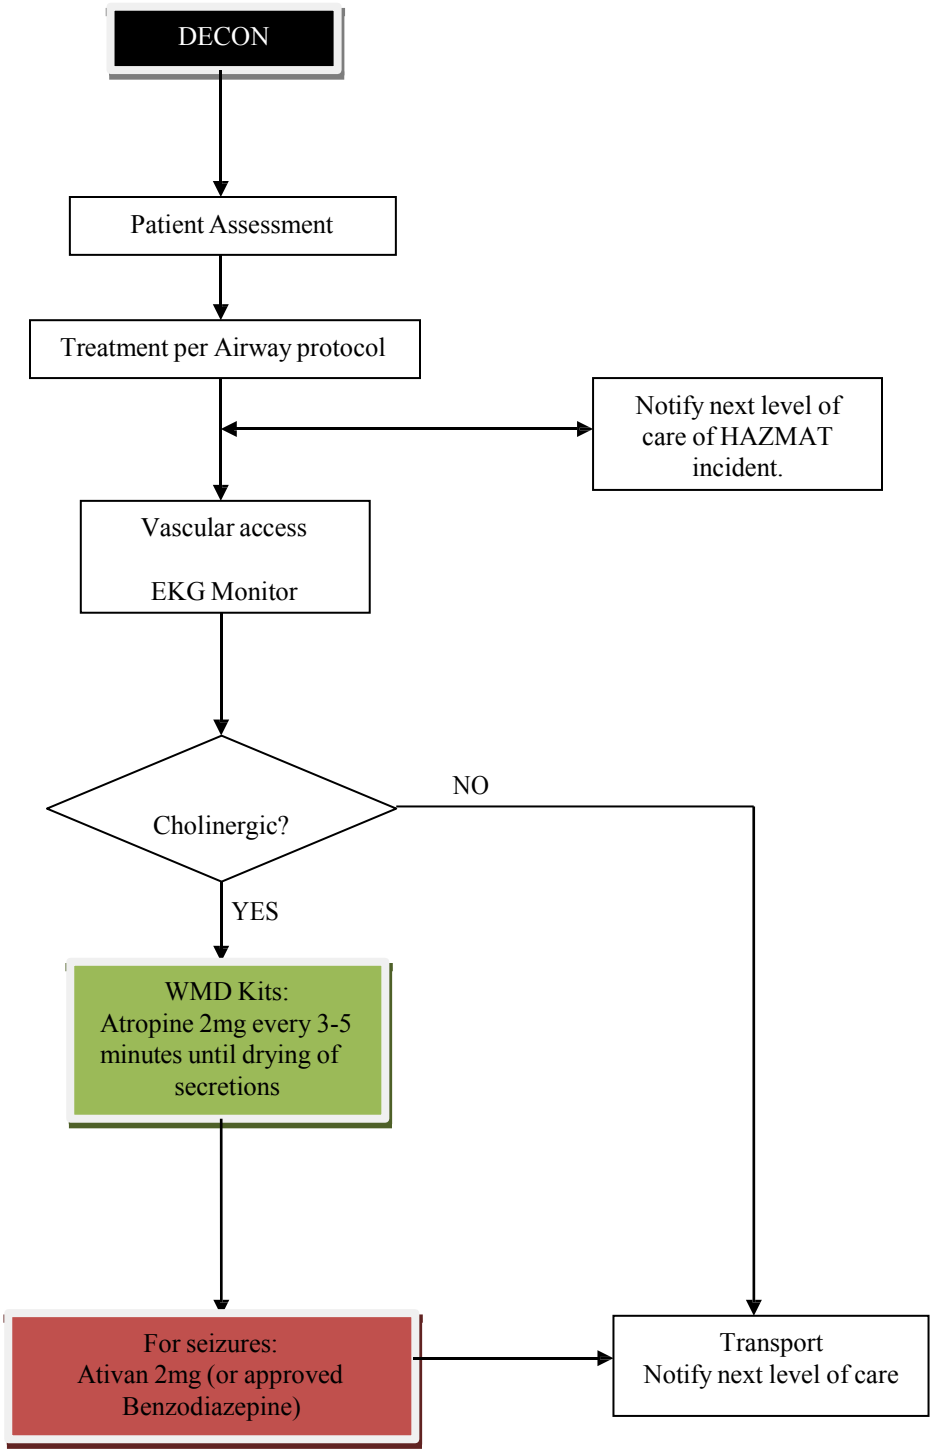
C. Warnings/Alerts:

1) Do not bring any hazardous material in the aircraft.

2) Do not use diuretics or nitroglycerin for patients with non-cardiogenic pulmonary edema.

3) PPE for the crew/providers is paramount when treating any suspected chemical exposure.

Chemical Exposure



III. ADULT PATIENT CARE PROTOCOLS

11. ***Chest Pain / AMI / ACS***

A. Objectives:

1) To assess and appropriately treat patients with chest pain or suspected AMI.

2) To eliminate patient's chest pain.

B. General Information:

1) Do not administer Aspirin in the following cases:
- HX of GI bleeding or bleeding disorders.
- HX of recent surgery
- Already taken max dose of Aspirin (324mg)
- Sensitivity / Allergy to aspirin

2) Nitroglycerin should be given to patients without IV/IO access only if blood pressure is > 100 mmHg.

3) Morphine may be administered concurrently with nitroglycerin.

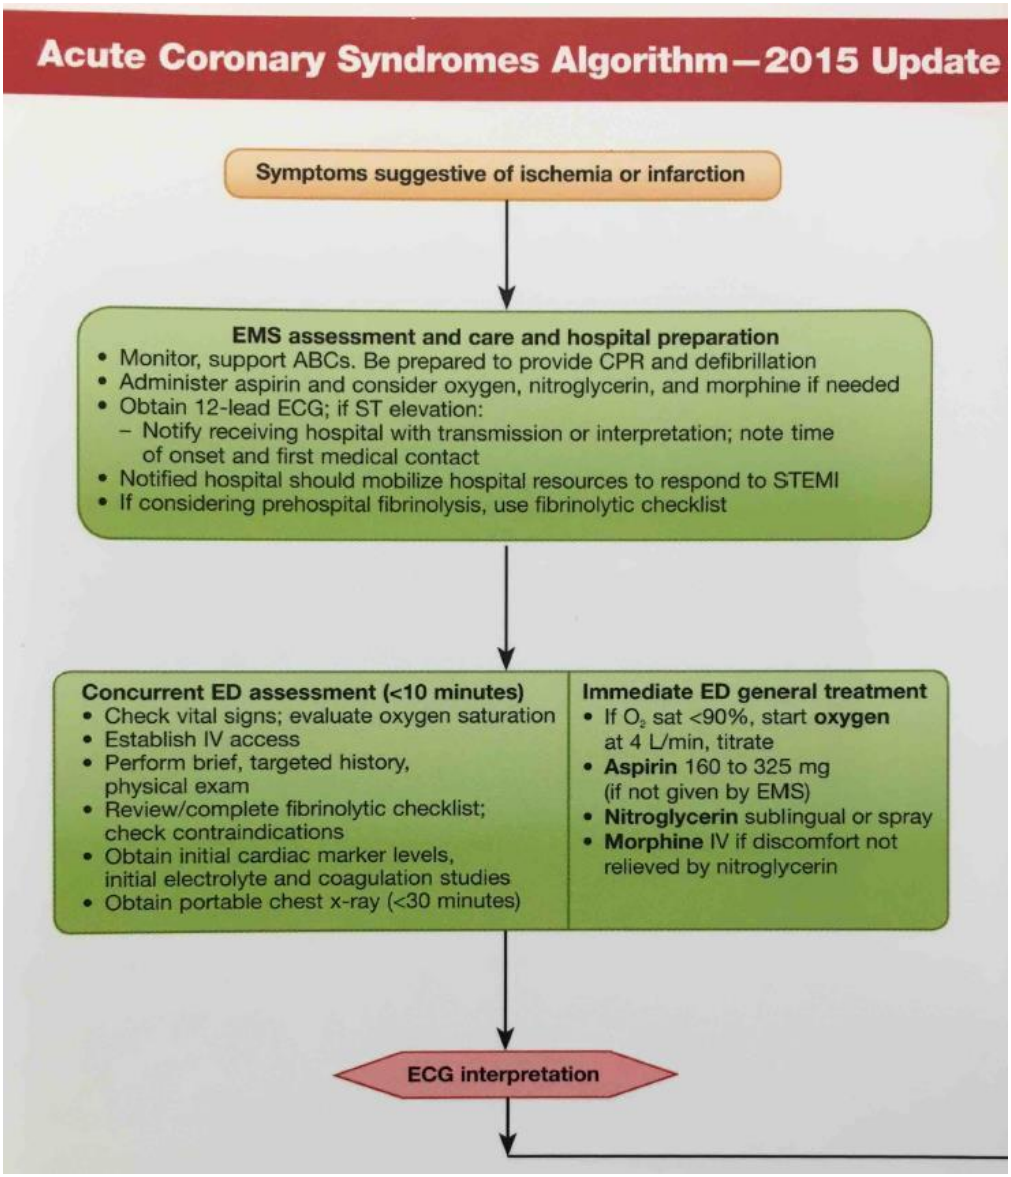
4) If the patient has cocaine-induced chest pain, Valium 5mg IV/IM may be given at discretion of Medical Control.

5) Do not delay patient treatment to obtain 12 Lead EKG.

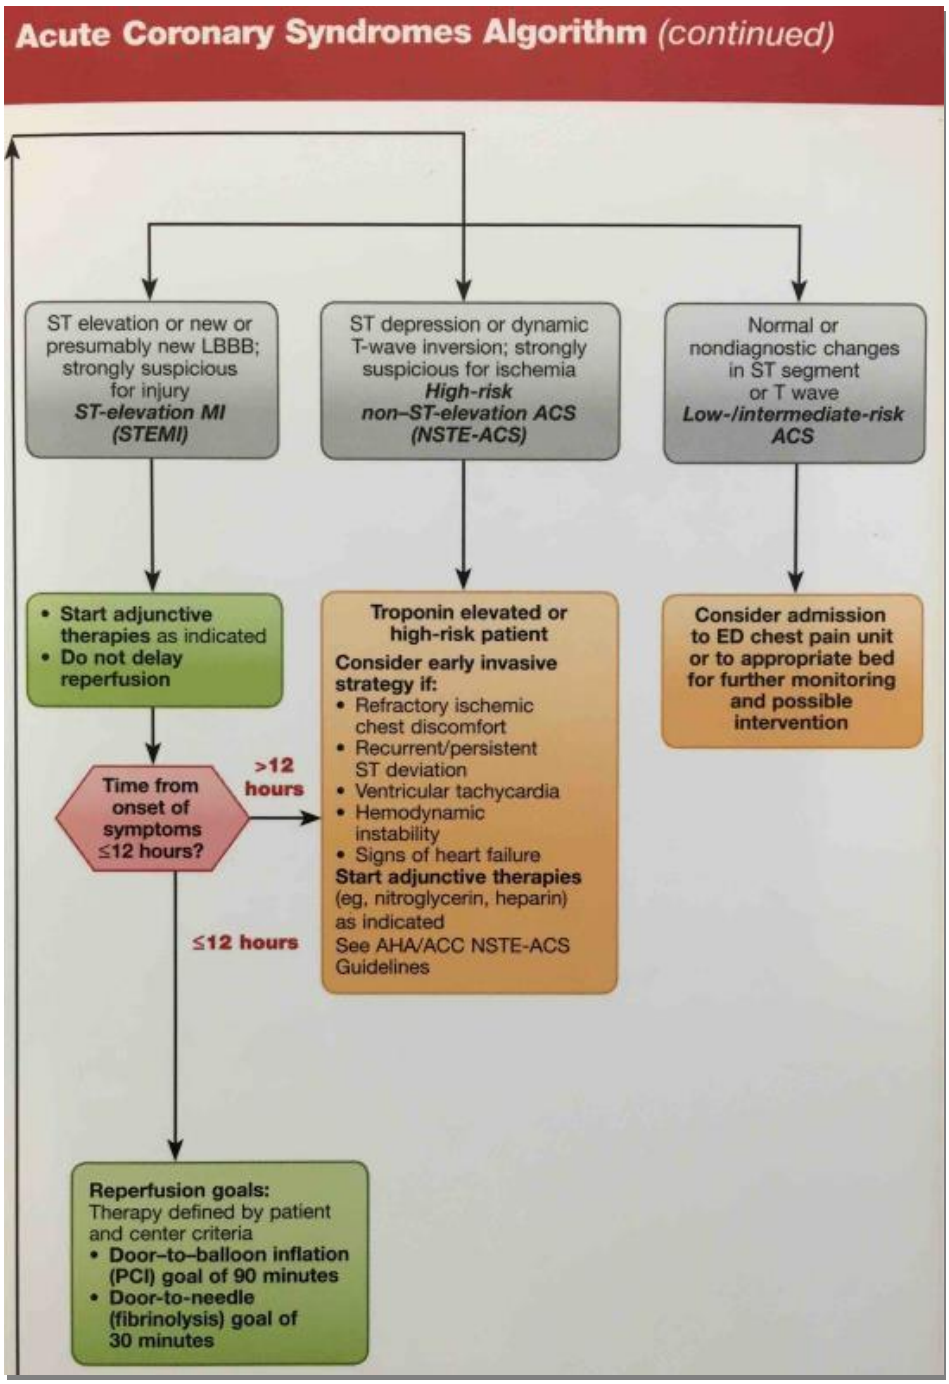
C. Warnings/Alerts:

1) Do not administer nitroglycerin to patients that have taken PDE inhibitors in the past 72 hours.

2) Do not administer more than three nitroglycerin doses in a 15-minute time period.



Acute Coronary Syndromes Algorithm—2015 Update
Symptoms suggestive of ischemia or infarction
EMS assessment and care and hospital preparation
• Monitor, support ABCs. Be prepared to provide CPR and defibrillation
• Administer aspirin and consider oxygen, nitroglycerin, and morphine if needed
• Obtain 12-lead ECG; if ST elevation:
– Notify receiving hospital with transmission or interpretation; note time of onset and first medical contact
• Notified hospital should mobilize hospital resources to respond to STEMI
• If considering prehospital fibrinolysis, use fibrinolytic checklist
Concurrent ED assessment (<10 minutes)
• Check vital signs; evaluate oxygen saturation
• Establish IV access
• Perform brief, targeted history, physical exam
• Review/complete fibrinolytic checklist; check contraindications
• Obtain initial cardiac marker levels, initial electrolyte and coagulation studies
• Obtain portable chest x-ray (<30 minutes)
Immediate ED general treatment
• If O_2 sat <90%, start **oxygen** at 4 L/min, titrate
• **Aspirin** 160 to 325 mg (if not given by EMS)
• **Nitroglycerin** sublingual or spray
• **Morphine** IV if discomfort not relieved by nitroglycerin
ECG interpretation



Acute Coronary Syndromes Algorithm (continued)
ST elevation or new or presumably new LBBB; strongly suspicious for injury
ST-elevation MI (STEMI)
ST depression or dynamic T-wave inversion; strongly suspicious for ischemia
High-risk non–ST-elevation ACS (NSTE-ACS)
Normal or nondiagnostic changes in ST segment or T wave
Low-/intermediate-risk ACS
• Start adjunctive therapies as indicated
• Do not delay reperfusion
Time from onset of symptoms ≤12 hours?
>12 hours
≤12 hours
Troponin elevated or high-risk patient
Consider early invasive strategy if:
• Refractory ischemic chest discomfort
• Recurrent/persistent ST deviation
• Ventricular tachycardia
• Hemodynamic instability
• Signs of heart failure
Start adjunctive therapies (eg, nitroglycerin, heparin) as indicated
See AHA/ACC NSTE-ACS Guidelines
Consider admission to ED chest pain unit or to appropriate bed for further monitoring and possible intervention
Reperfusion goals:
Therapy defined by patient and center criteria
• Door–to–balloon inflation (PCI) goal of 90 minutes
• Door-to-needle (fibrinolysis) goal of 30 minutes

PAGE INTENTIONALLY

LEFT BLANK

III. ADULT PATIENT CARE PROTOCOLS

12. *Combative Patient*

A. Objectives:

1) To assess and appropriately treat a patient who is combative.

2) To ensure patient safety and safety for Aircrew.

B. General Information:

1) All patients shall be disarmed by ground medics before transport to aircraft.

2) Physical Restraint Guidelines:
- Soft restraints may be sufficient
- If Law enforcement is available, use their restraints under their supervision
- Do not endanger yourself, crew, or aircraft
- Flex cuffs, zip ties, or tie downs are authorized for in-flight environment restraints

3) Avoid placing restraints in such a way as to preclude evaluation of the patient or will cause further harm.

4) Chemical Restraint Guidelines:
- Sedative agents may be used to provide safe, humane method of restraining the violently combative patient. Ativan 2mg IM or Ketamine 2-4mg/kg
- Consider 50mg IV/IM diphenhydramine (Benadryl) if patient exhibits signs of dystonic reaction.

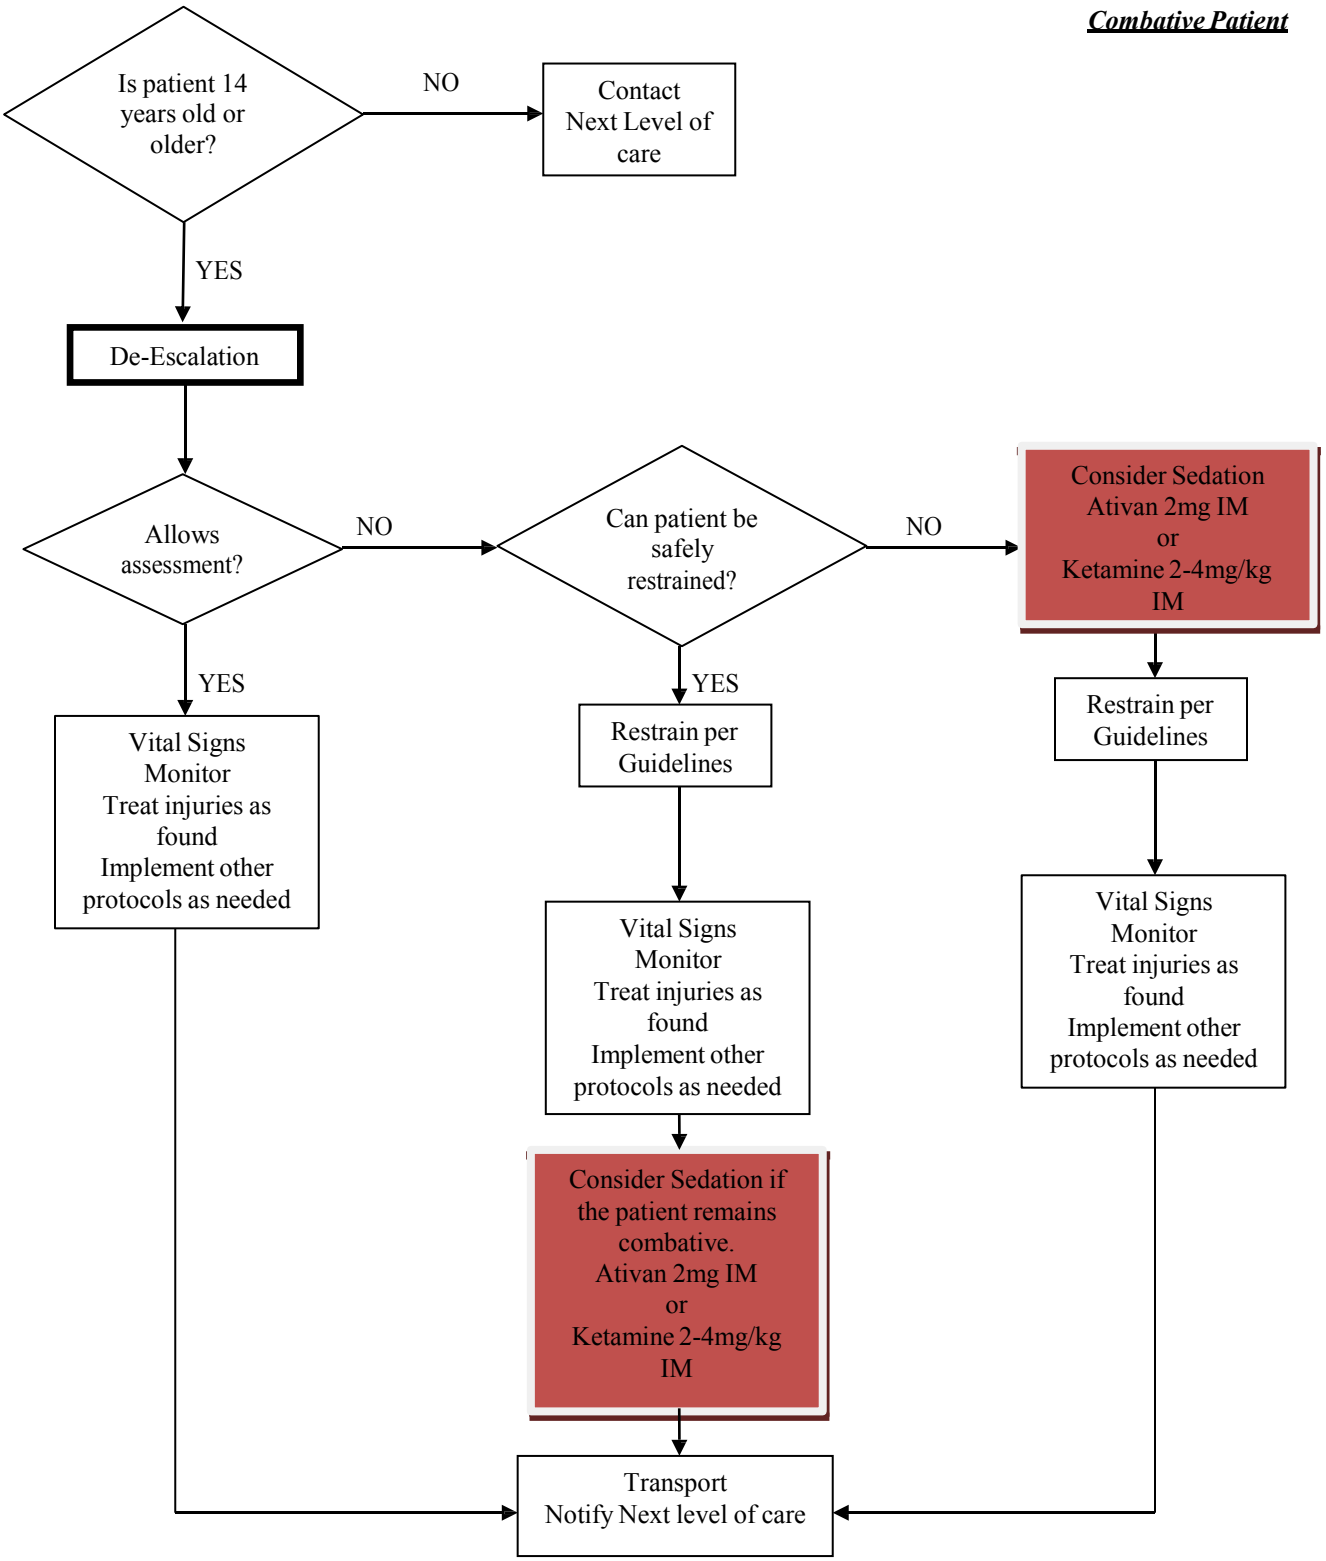
C. Warnings/Alerts:

1) All patients who receive chemical restraints shall be physically restrained.

2) Consider closed head injury/brain bleed in cases of combative patients. Complete neurologic assessment shall be completed and documented.

3) Providers shall avoid using any other restraints other than the once listed.

Combative Patient



Is patient 14 years old or older?
NO

III. ADULT PATIENT CARE PROTOCOLS

13. ***Crush Syndrome***

A. Objectives:

1) To assess and appropriately treat patients with suspected crush injuries/syndrome.

B. General Information:

1) Entrapped patients under heavy loads greater than 30 minutes shall be treated as suspected crush syndrome.

2) Serious signs and symptoms are:
- Hypotension
- Hypothermia
- Abnormal ECG findings
- Pain
- Anxiety

C. Warnings/Alerts:

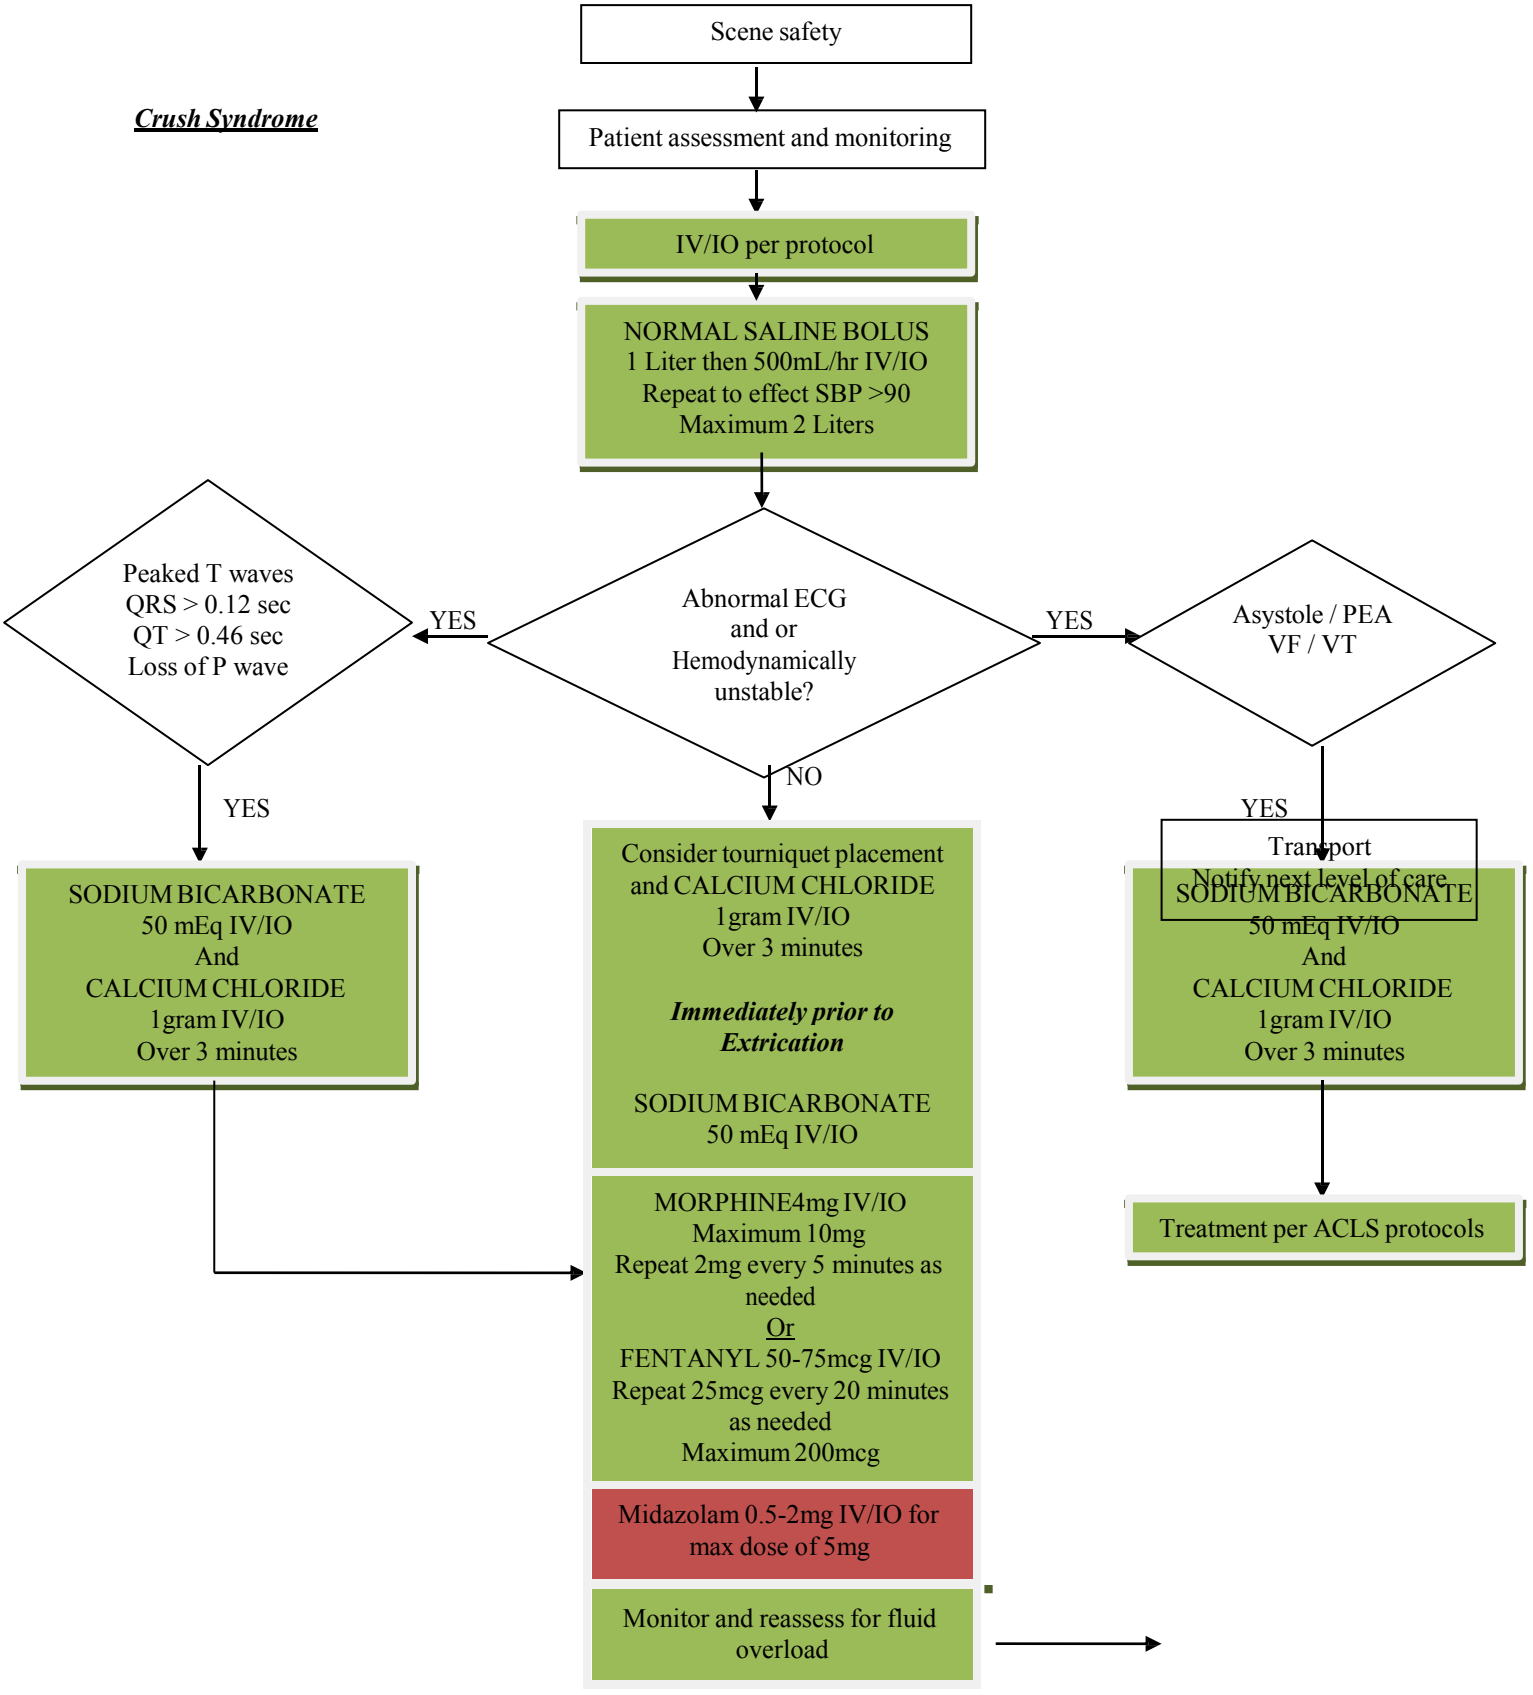
1) Scene safety is of paramount importance as typical scenes pose hazards to rescuers. Call for appropriate resources.

2) Avoid Ringers Lactate IV solution due to potential worsening of hyperkalemia.

3) Hyperkalemia from crush syndrome can produce ECG changes described in protocol, but may also be a bizarre wide complex rhythm. Wide complex rhythms should also be treated using VF/Pulseless VT Protocol with the focus on hyperkalemia.

4) Patients may become hypothermic even in warm environments.

Crush Syndrome



III. ADULT PATIENT CARE PROTOCOLS

14. *Dialysis/ Renal Failure*

A. Objectives:

1) To assess and appropriately treat patients who receive dialysis.

B. General Information:

1) Dialysis patients are very susceptible to electrolyte imbalances and hypoglycemia.

2) Serious signs and symptoms of electrolyte imbalances are:
- Weakness
- Chest pain / pressure
- Peaked T waves on an EKG
- Hypo/Hypertension
- Pulmonary Edema
- Headaches
- Dizziness

3) Blood pressure and IV's shall not be taken or given on extremities with shunts.

4) Bleeding from shunts can be difficult to control, do not apply tourniquet directly on top of shunt. If possible, apply tourniquet above the affected area.

5) For cardiac arrest in dialysis patients, calcium chloride 1g IV/IO followed by 40ml flush and sodium bicarbonate 1 meq/kg IV/IO should be administered as first line medications.

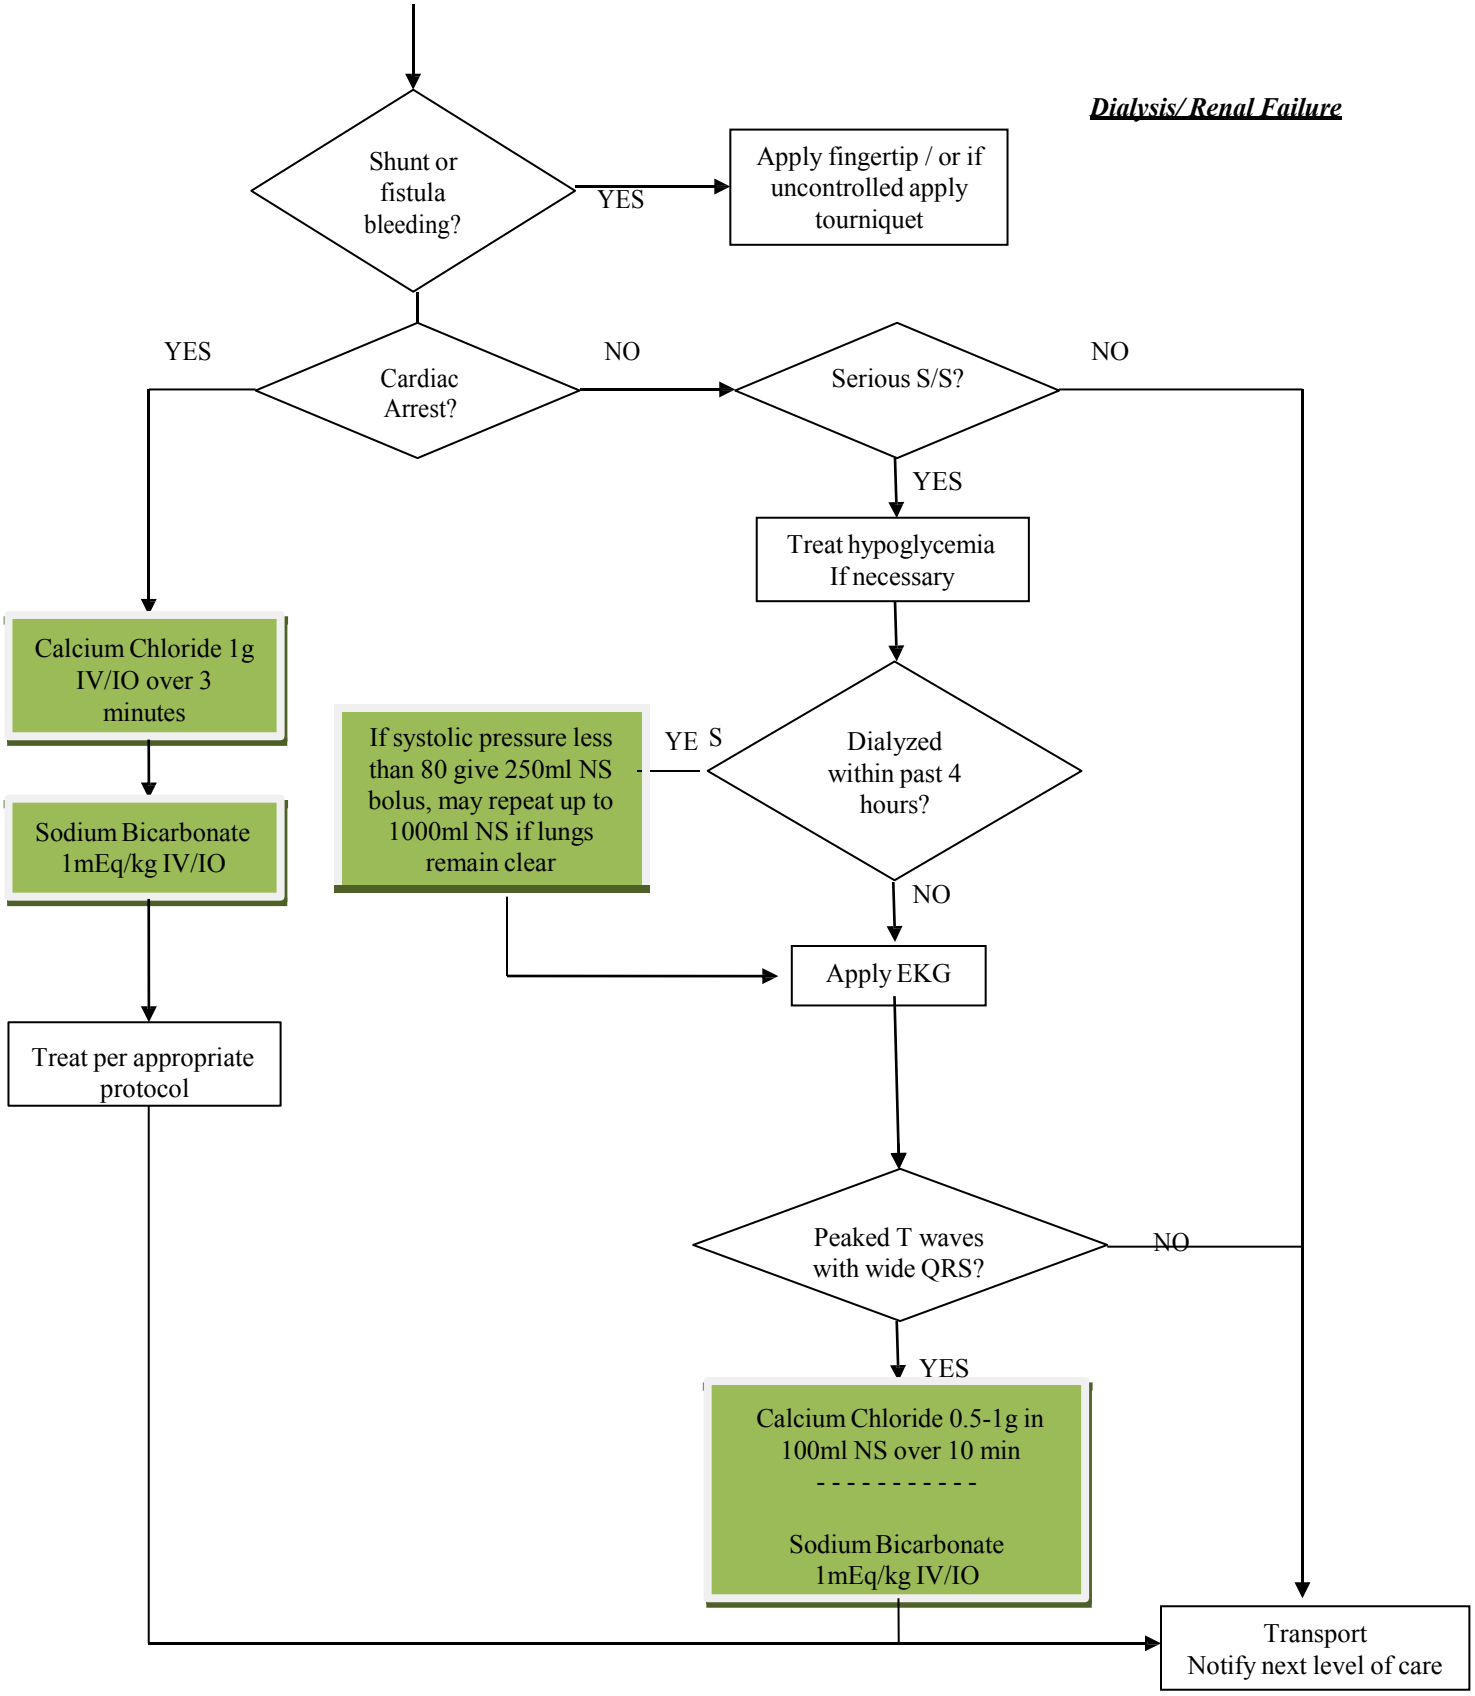
C. Warnings/Alerts:

1) Do not use tourniquets directly on shunt or fistula.

2) Do not give magnesium sulfate to renal failure patients.

3) Flush IV lines thoroughly between sodium bicarbonate and calcium chloride administration.

Dialysis/ Renal Failure



Shunt or fistula bleeding?

Transport
Notify next level of care

III. ADULT PATIENT CARE PROTOCOLS

15. *Diving Medical Disorders / Flight Physiology Events*

A. Objectives:

1) To assess and appropriately treat patients who are experiencing a diving medical disorder

B. General Information:

1) Altitude precautions shall be considered in transporting these patients.

2) 100% O_2 via non rebreather if patient is conscious shall be applied, to flush out all N2 from the blood stream.

3) The patients diving gear shall be transported with the patient. (I.E tanks, depth gauge, dive watch, rebreathing apparatus, etc…)

4) Maintain Carboxyhemoglobin levels via RAD57 Device at 1-5%. Any reading over 5% after a Flight Physiology event shall be placed on 100% O_2 via NRB until levels are less than 5%.

C. Warnings/Alerts:

1) Transport patients in supine position.

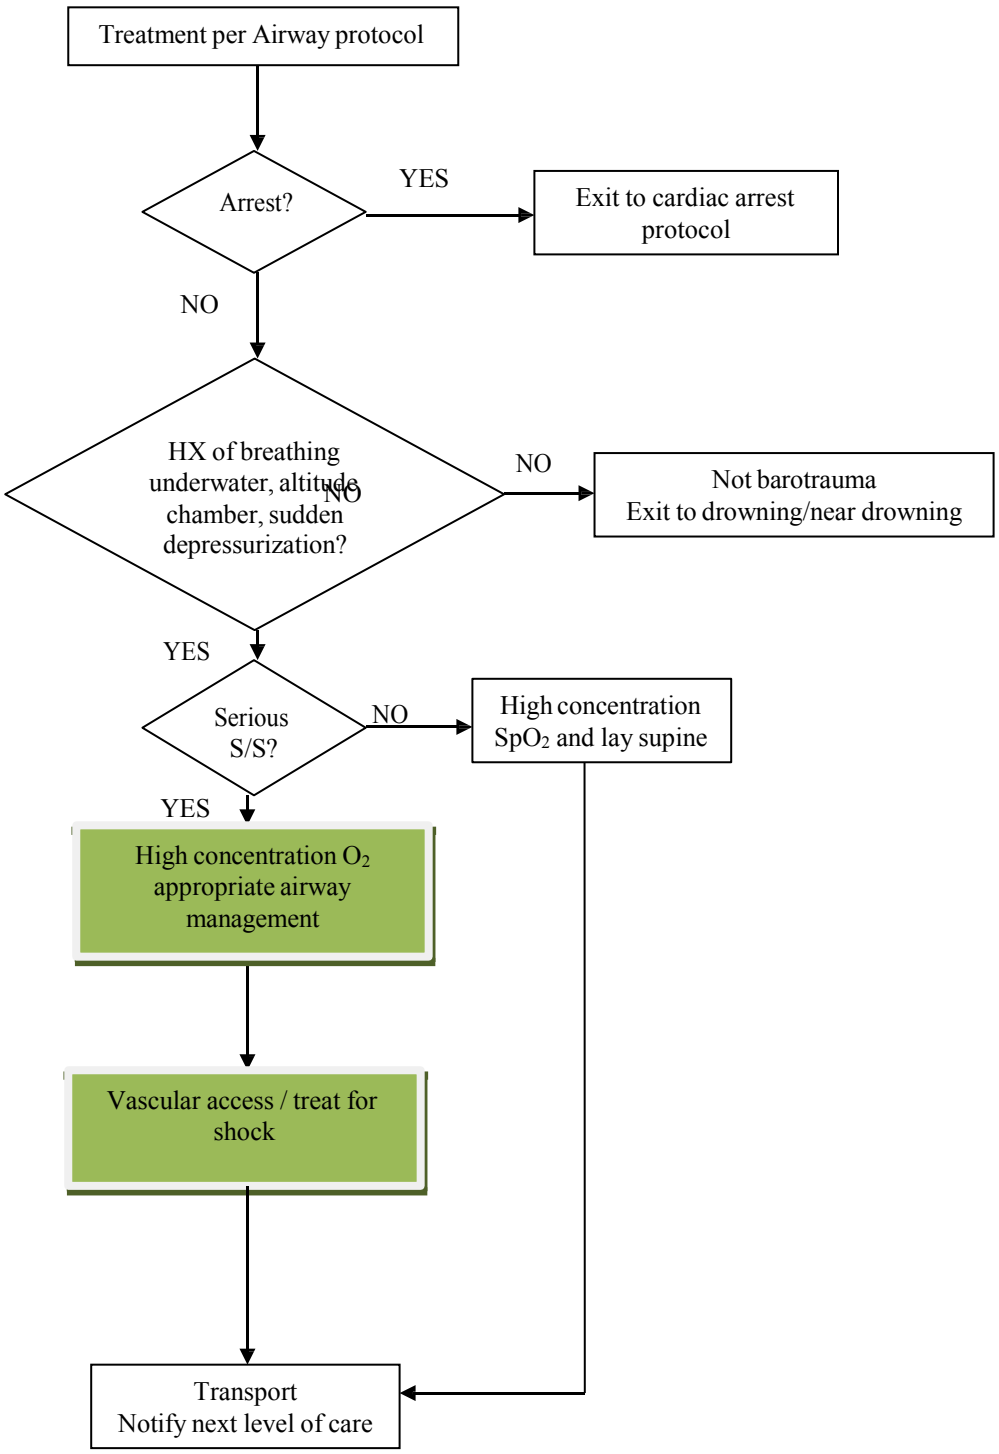
2) Only transport to facilities with hyperbaric chambers in local area.
Diving Alert Network (Duke University): 919-684-9111
For information on closest chamber: http://www.diversalertnetwork.org/

3) Increasing altitude for these patients can severely increase signs and symptoms or cause fatal harm.

D. Notes:

1) Dive Medical HX:
   a. Type of dive performed, depth, duration.
   b. Number of dives in the last 24hrs.
   c. When were the symptoms noticed: Before, during, or after the dive.
   d. Was it during descending, the bottom or ascending?
   e. Has the symptom/s increased, decreased, or stayed the same.
   f. Have you ever had DCS or AGE before, when?

Diving Medical Disorders



III. ADULT PATIENT CARE PROTOCOLS

16. *Drowning / Near Drowning*

A. Objectives:

1) To assess and appropriately treat patients who have experienced a submersion injury.

B. Warnings/Alerts:

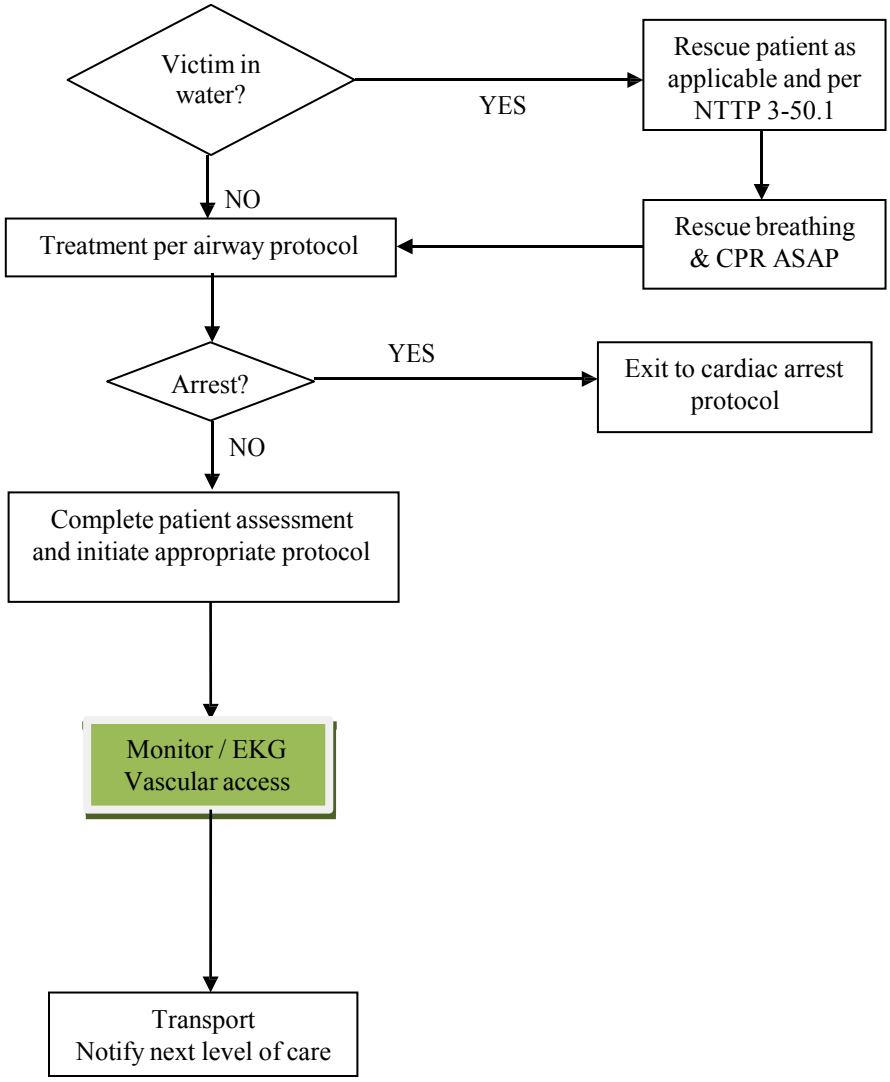
1) All patients with submersion incidents shall be transported for evaluation. Patients are in high risk of developing life-threatening pulmonary edema within 72 hours of incident.

2) Do not insert an NG tube without securing the airway with an ET tube.

3) Patients shall be considered for C-spine precautions, as diving injuries are associated with spinal injury.

4) Drowning is the leading cause of death among would-be rescuers.

Drowning / Near Drowning



III. ADULT PATIENT CARE PROTOCOLS

17. ***Head Injury / Suspected TBI***

A. Objectives:

1) To appropriately assess, treat, and manage patients with head injuries / suspected traumatic brain injuries.

2) To maintain adequate airway and oxygenation, maintain $EtCO_2$ 35-40 mmHg.

3) Establish and maintain adequate perfusion to vital organs or to sustain life until further care.

4) Appropriately administer the Military Acute Concussion Evaluation (MACE).

B. General Information:

1) Little that can be done to correct the primary injury in the prehospital environment. The primary goal is to prevent secondary injuries associated with hypoxia, hypotension, anemia, and both hyper/hypothermia.

2) The hallmark sign is altered level of consciousness. The optimal assessment includes AVPU, neurological evaluation, and MACE 2 exam.

3) The use of low altitude flight shall be considered in transportation of these patients.

C. Warnings/Alerts:

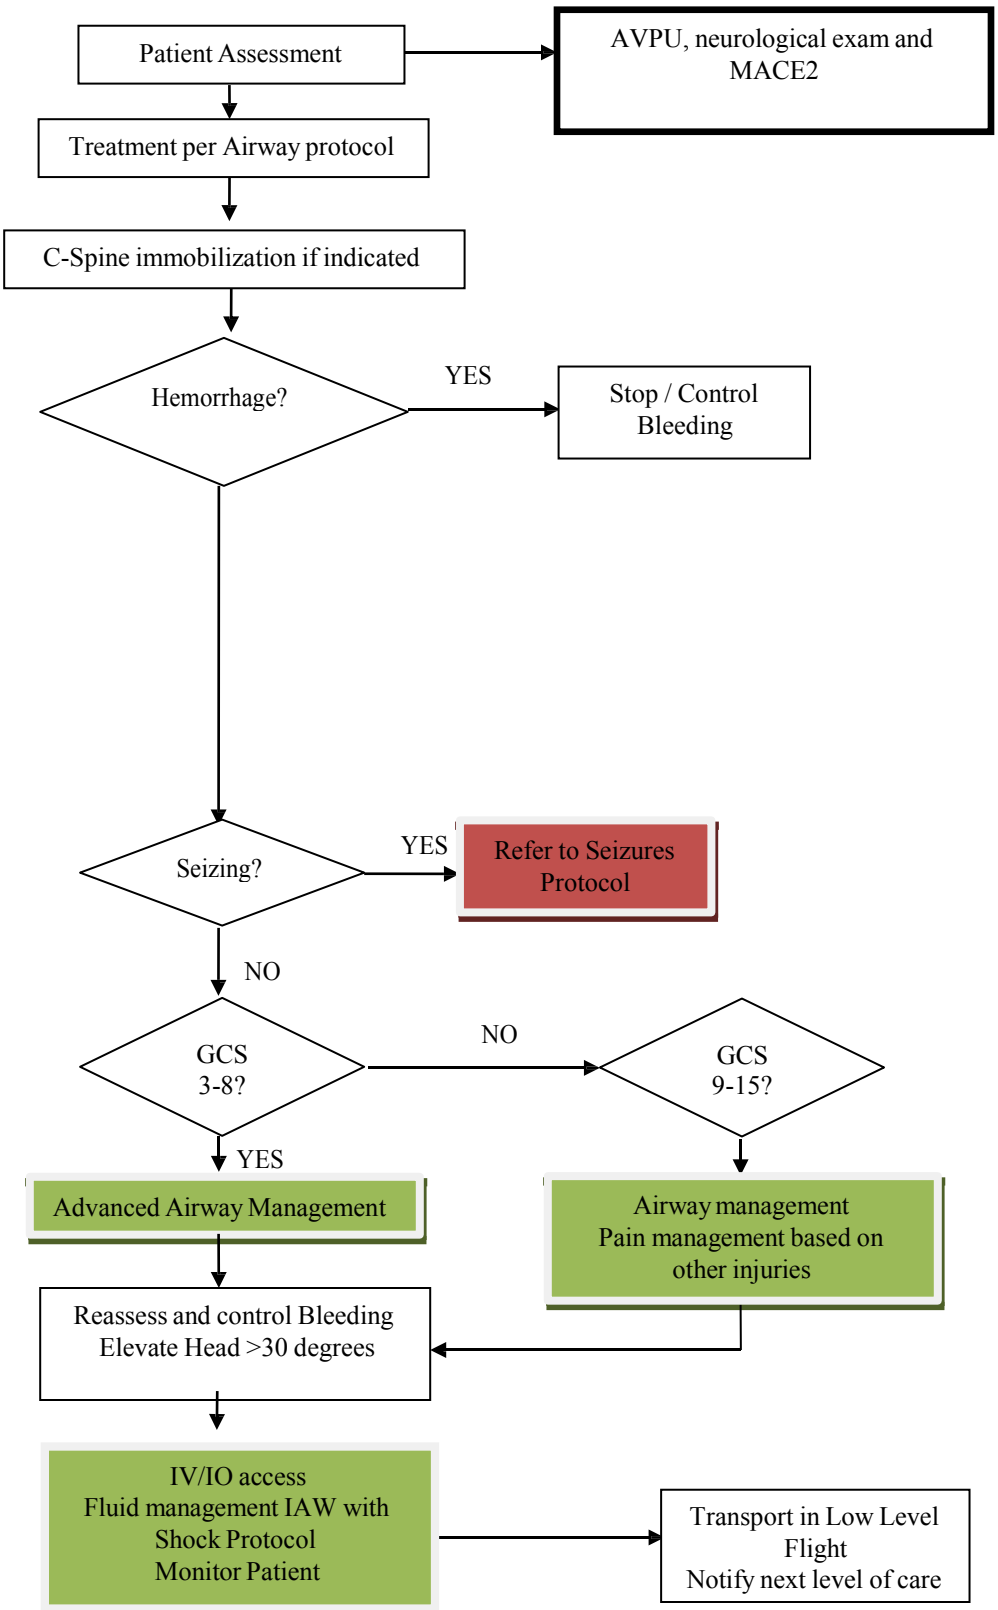
1) Do not elevate the feet to treat for shock.

2) Administer fluids to maintain MAP of 85mmHg.

3) There are many medications with contradictions associated with ICP, with most of them being Analgesics. Be cautious in the medication given and consult OMD or the medication reference in the back of these protocols for further guidance.

4) Hyperventilation is NOT recommended in treatment of these patients.

Head Injury / Suspected TBI



Refer to XI. MILITARY ACUTE CONCUSSION EVALUATION

(MACE) 2ND EDITION on page 206, for all suspected Head Injury

and Traumatic Brain Injury patients that ARE DOD entities.

PAGE INTENTIONALLY

LEFT BLANK

III. ADULT PATIENT CARE PROTOCOLS

18. *Hyper / Hypoglycemia*

A. Objectives:

1) To assess and appropriately treat patients with Hyper / Hypoglycemia.

B. General Information:

1) Dextrose 50% may be administered rectally.

2) Dextrose administration requires a patent IV line, not a saline lock.

3) Malnourished patients or suffering from severe dehydration may need Thiamine to properly metabolize dextrose.

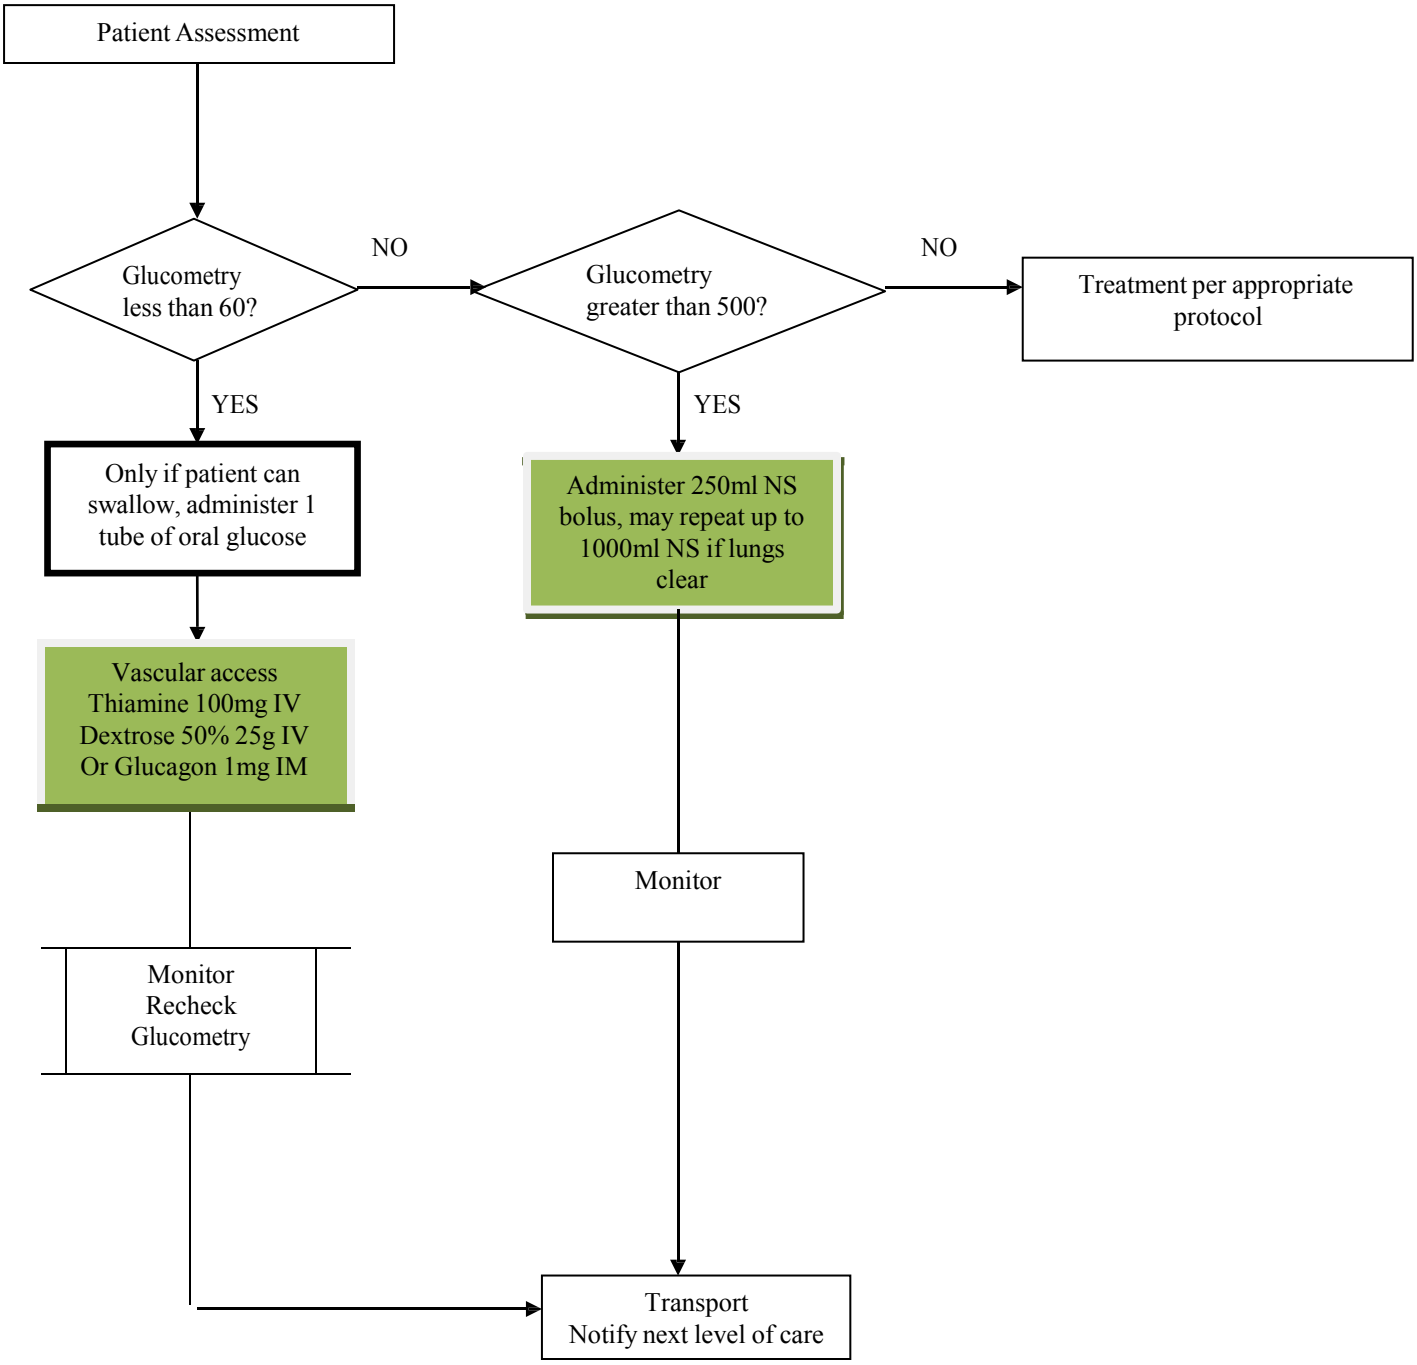
C. Warnings/Alerts:

1) Do not administer oral glucose to patients that are not able to swallow or protect their own airway.

2) If the IV line infiltrates while administering Dextrose, stop dextrose administration immediately.

3) Patients shall have their weapons removed for patient safety.

Hyper / Hypoglycemia



III. ADULT PATIENT CARE PROTOCOLS

19. *Hyperthermia*

A. Objectives:

1) To assess and appropriately treat patients who are hyperthermic.

B. General Information:

1) Administer oral fluids if patient can swallow – water and half-strength electrolyte solution

2) Active cooling measures:
- Air moving across wet skin
- Ice packs at axilla, groin, neck
- Doors and windows of aircraft should be open based on environment to help cooling

C. Warnings/Alerts:

1) Heat stroke is a life-threatening emergency, do not delay transport.

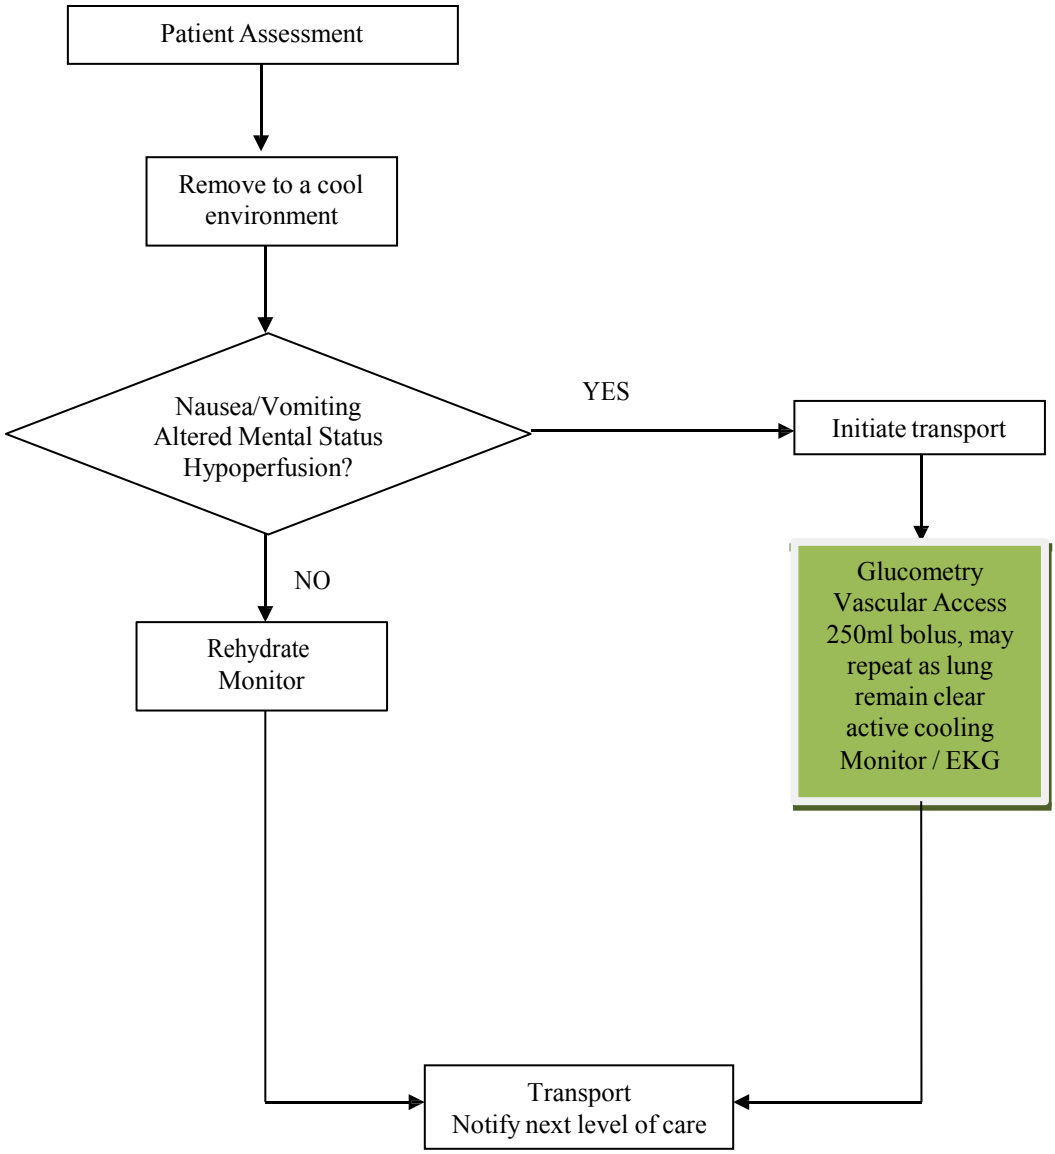
2) Patients shall have their weapons removed for patient safety.

3) Do not exceed 2000ml of IV fluids unless directed to by Medical Control.

4) Cease active cooling when core temperature has been lowered to102 degrees F and continue to monitor.

5) Cocaine, ecstasy, amphetamines, and aspirin toxicity can all raise body temperatures.

Hyperthermia



III. ADULT PATIENT CARE PROTOCOLS

20. *Hypothermia*

A. Objectives

1) To assess and appropriately treat patients who are hypothermic.

B. General Information:

1) Remove all of the patient's wet clothing.

2) Cover the patient with blankets or Hypothermia Kits.

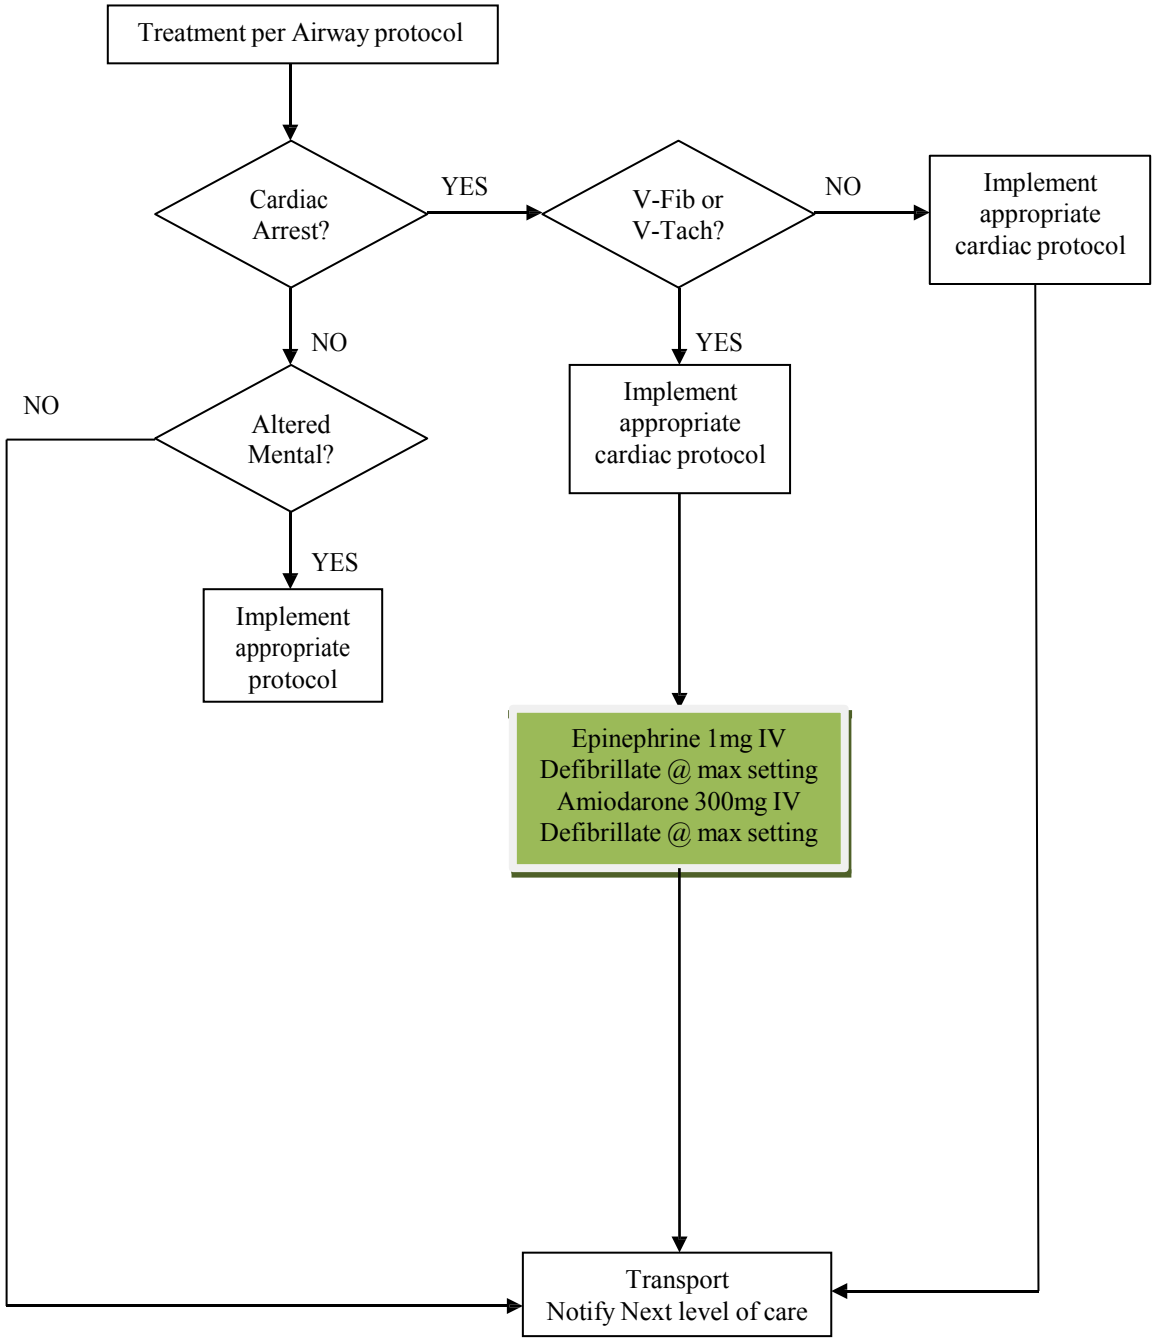
3) Hypothermia is defined as a core temperature <95F (35C)
- With temperatures <31C (88F) ventricular fibrillation is common. Cardiac muscle is very irritable and rough handling of patients at these temperatures can result in cardiac dysrhythmias.
- Core temperatures below 30C (86F) ceases shivering.

C. Warnings/Alerts:

1) 1) Handle hypothermic patients gently to avoid spontaneous conversion into ventricular fibrillation. Avoid aggressive rewarming, sudden movements, and/or rough handling in severe hypothermia patients.

2) Severe hypothermic patients can present with Rigor Mortis. Providers should attempt resuscitation unless clear evidence of irreversible death.

Hypothermia



III. ADULT PATIENT CARE PROTOCOLS

21. *Nausea / Vomiting*

A. Objectives

1) To assess and appropriately treat patients who are profoundly nauseous and vomiting.

B. General Information:

1) Nausea and Vomiting generally are not life-threatening conditions.

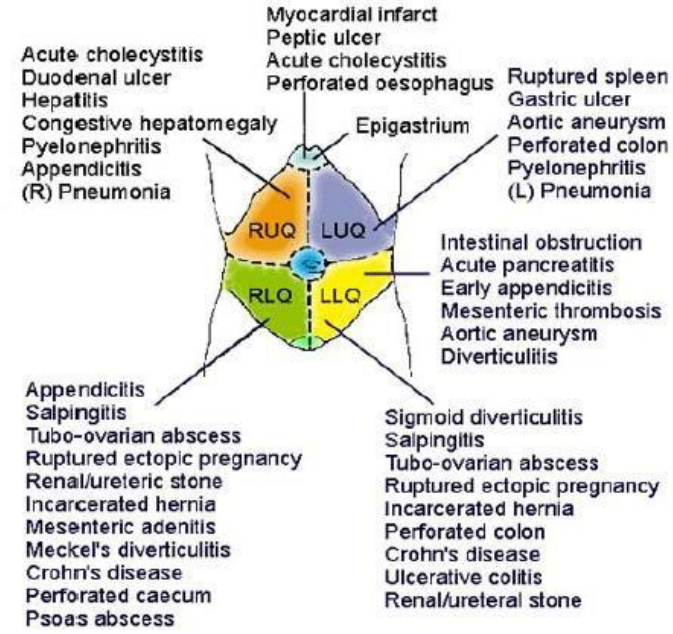
2) Suction should be readily available.

3) Zofran (Ondansetron) or Phenergan (Promethazine) may be administered to patients with vomiting. Medication is highly recommended for in-flight transport.

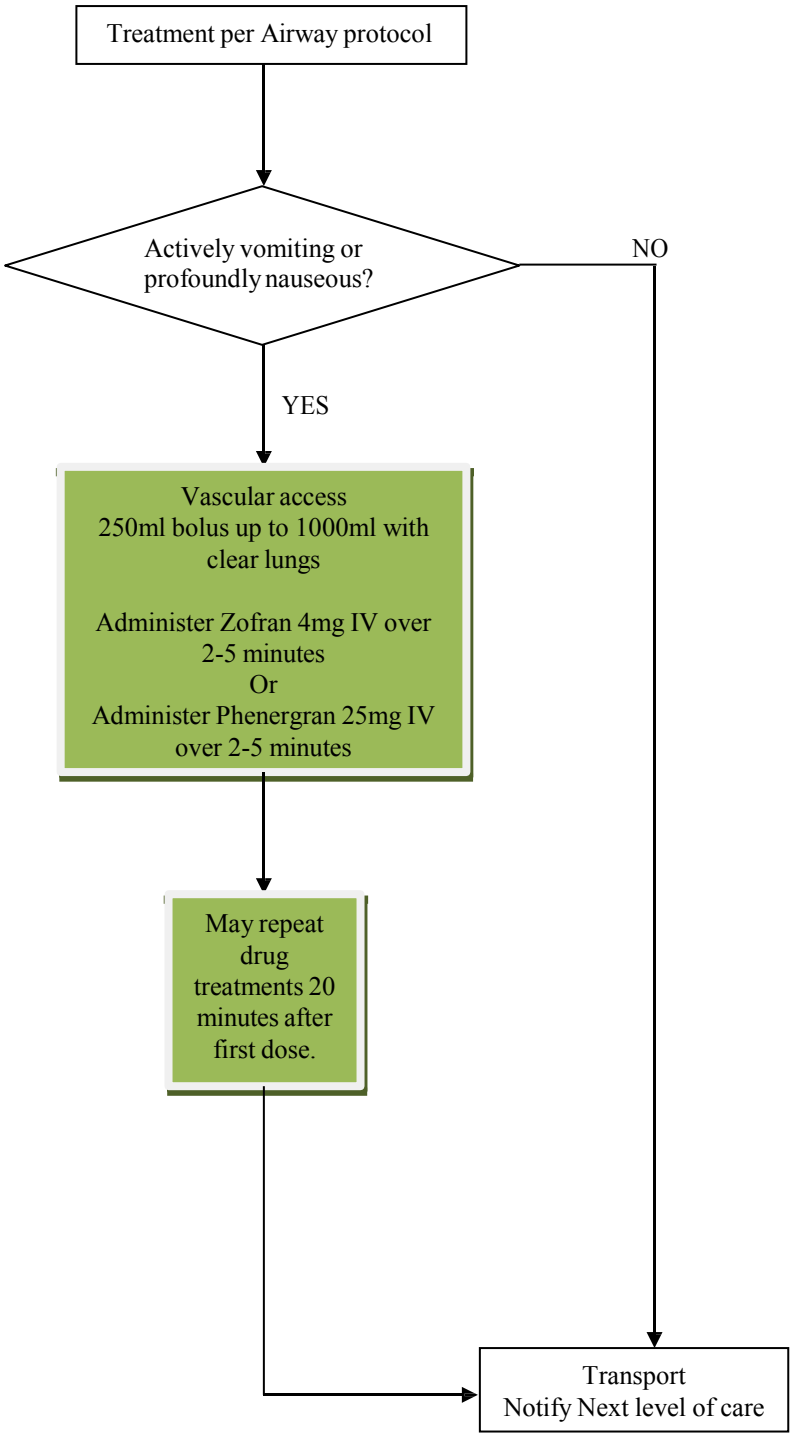
4) Zofran – 4mg slow IV push or IM if IV not available
Phenergan – 25mg IV push or IM if IV not available

C. Warnings/Alerts:

1) Ventilating an unconscious vomiting patient will produce aspiration and airway obstruction, suctioning and advanced airway management is essential.



Nausea / Vomiting



Treatment per Airway protocol
Actively vomiting or profoundly nauseous?
NO
YES
Vascular access
250ml bolus up to 1000ml with clear lungs
Administer Zofran 4mg IV over 2-5 minutes
Or
Administer Phenergran 25mg IV over 2-5 minutes
May repeat drug treatments 20 minutes after first dose.
Transport
Notify Next level of care

III. ADULT PATIENT CARE PROTOCOLS

22. ***OB / GYN – Pregnancy / Delivery / Vaginal Bleeding***

A. Objectives

1) To appropriately access and manage out-of-hospital births.

2) To appropriately access and manage patients with vaginal bleeding.

B. General information:

1) Obtain functional HX:
- Premature?
- Multiple births?
- Meconium?
- Prenatal care?
- Narcotic use?

2) Transport patients in left lateral recumbent position.

3) Vaginal bleeding is considered moderate to severe if the patient has lost more than 500ml of blood or if she is using 1 heavy pad/hour or more.

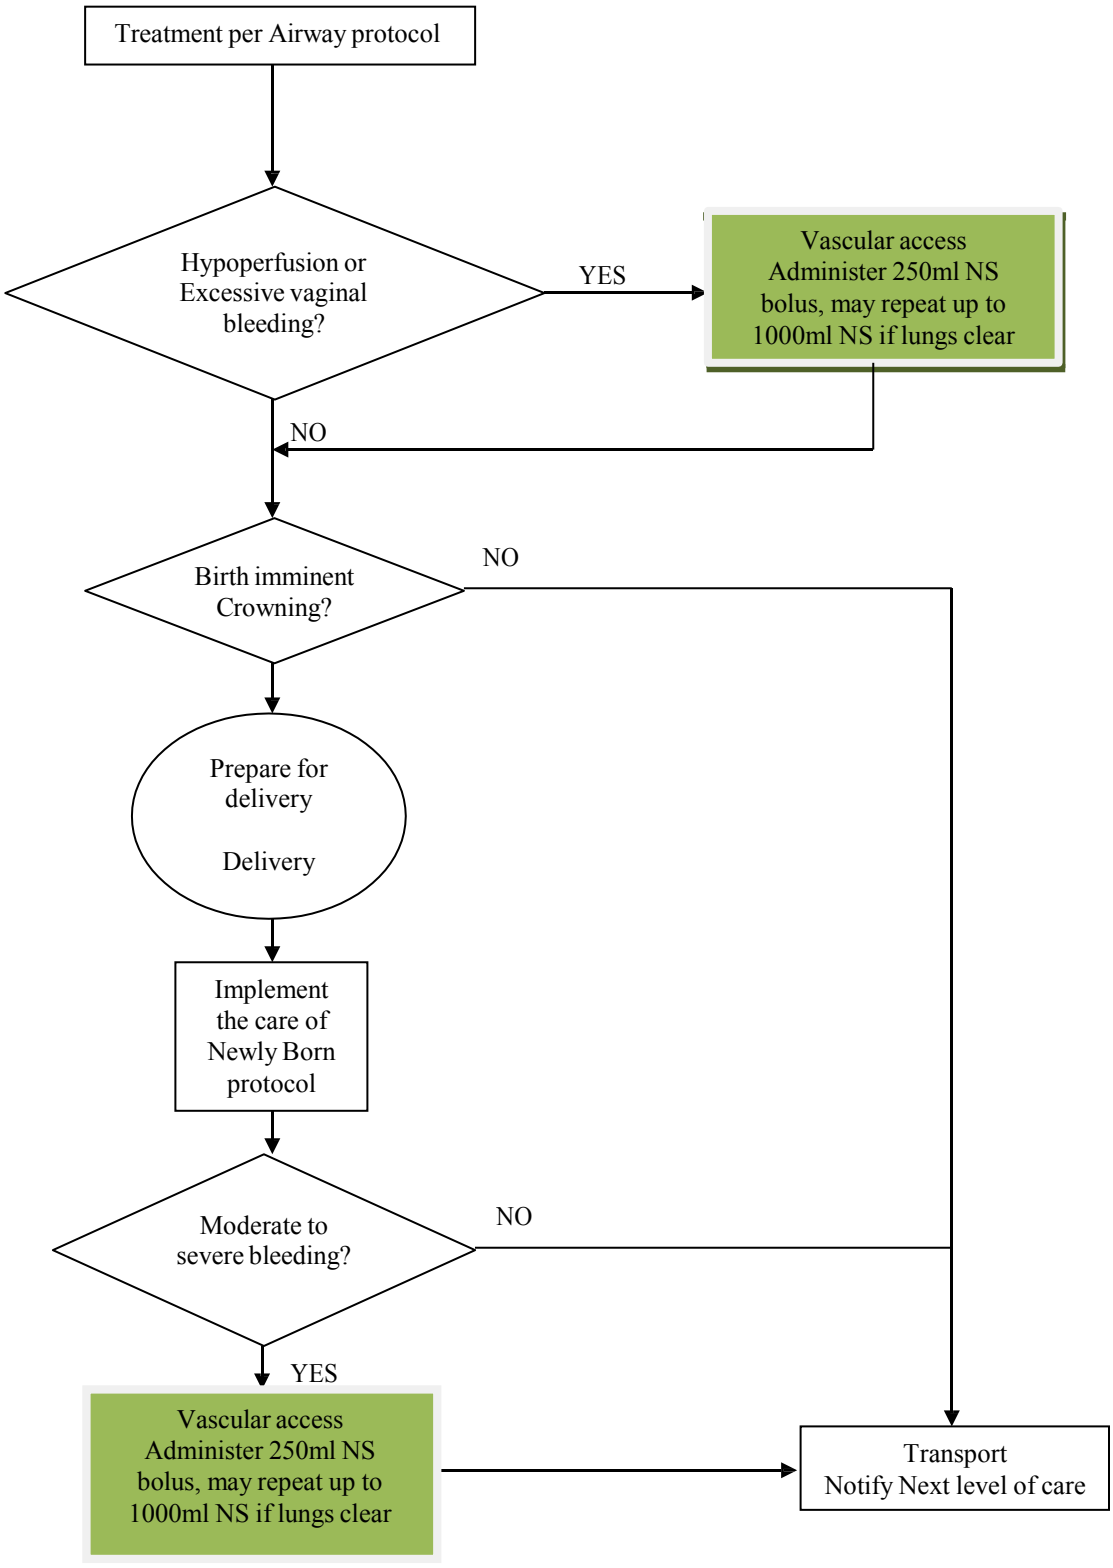
4) With severe vaginal bleeding post birth, consider uterine massage for placental delivery.

C. Warnings/Alerts:

1) Do not assume that vaginal bleeding is due to normal menstruation.

2) Third-trimester bleeding is never normal and can be life-threatening to the mother and fetus.

OB / GYN – Pregnancy / Delivery / Vaginal Bleeding



Treatment per Airway protocol
Hypoperfusion or Excessive vaginal bleeding?
YES
Vascular access Administer 250ml NS bolus, may repeat up to 1000ml NS if lungs clear
NO
Birth imminent Crowning?
NO
Prepare for delivery
Delivery
Implement the care of Newly Born protocol
Moderate to severe bleeding?
NO
YES
Vascular access Administer 250ml NS bolus, may repeat up to 1000ml NS if lungs clear
Transport Notify Next level of care

III. ADULT PATIENT CARE PROTOCOLS

23. *OB / GYN – (Pre) Eclampsia*

A. Objectives

1) To appropriately access and treat patients with pre-eclampsia or eclampsia.

B. General Information:

1) Pre-eclampsia may occur for up to 18weeks pre-birth - 8weeks post-partum.

2) Ativan (lorazapam) is preferred drug for seizures
- Dose is 2mg slow IV push, dilute in NS

Valium (Diazepam) is first line treatment for seizing patients
- Dose is 5mg slow IV push over 2 minutes

Magnesium Sulfate is treatment to control eclampsia
- Dose is 2g in 100ml over 5 minutes

3) Transport patient in left lateral recumbent position.

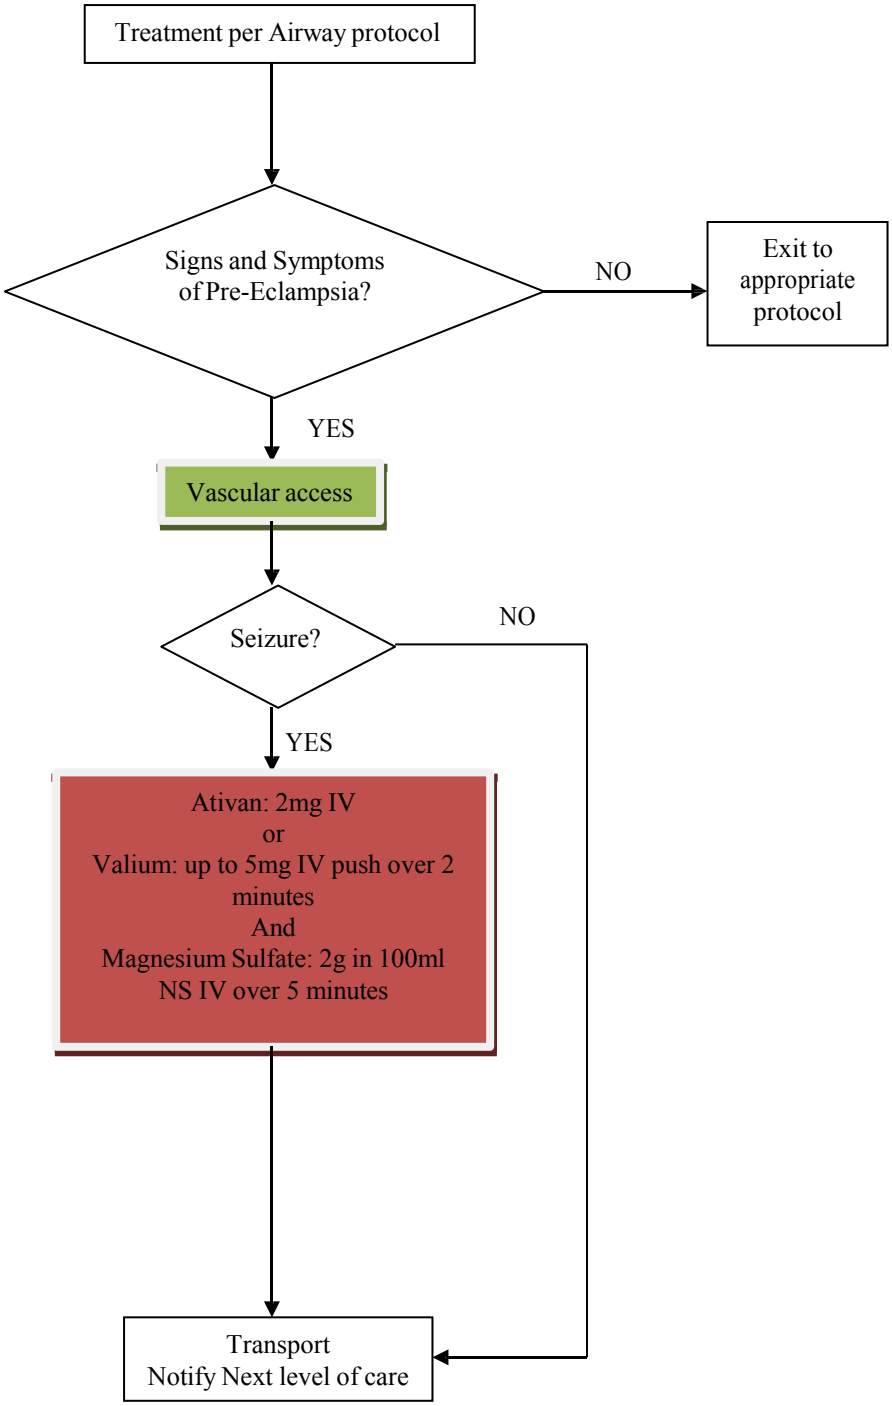
C. Warnings/Alerts:

1) Use caution in administering magnesium sulfate to patients in renal failure.

2) Valium has the potential to cause respiratory depression and bradycardia, patients shall be monitored. After Valium administration, flush IV lines thoroughly.

3) Monitor closely for elevated blood pressure based on the patient's normal baseline.

OB / GYN – (Pre) Eclampsia



III. ADULT PATIENT CARE PROTOCOLS

24. *Pain Management Non-Cardiac*

A. Objectives

1) To assess and appropriately treat non-cardiac pain.

B. General Information:

1) Pain is an important indicator of disease or injury, but generally under treated in the prehospital environment. Pain management is associated with a reduction in PTSD symptoms after traumatic injury.

2) Pain management medications:
- Morphine: 2mg IV or IM with a maximum total dose 10mg
- Should be administered via slow IV push

- Fentanyl: 1mcg/kg, for a max dose of 100mcg.
- Shall be slow IV push
- May be used IM or IN.

- Ketamine: 20mg IV/IO over 1 minute
50mg IM
50mg Intranasal / Atomizer every 30-60min as needed for severe pain

3) Implement Nausea / vomiting protocol as needed.

C. Warnings/Alerts:

1) Patients who receive pain medications shall receive cardiac and SpO_2 monitoring.

2) Naloxone shall be on hand with the administration of opioid medications to counter-act respiratory depression.
- Naloxone: 0.4-2mg titrated to effect, or respiratory depression improves.

3) The mixing the of analgesics should be avoided in pain management. In the event mixing of analgesics, documentation of why needs to be completed on the DA4700.

Treatment per Airway protocol

Assess pain and severity

Mild/Moderate pain 1-5?

Severe pain 6-10?

Vascular access

Fentanyl 1mcg/kg IV/IO, for a max dose of 100mcg fix

Vascular access

Fentanyl 1mcg/kg IV/IO, for a max dose of 100mcg

Or

Ketamine 20mg IV/IO
50mg IM/IN

Nausea / Vomiting protocol as needed

Transport
Notify Next level of care

III. ADULT PATIENT CARE PROTOCOLS

25. *Post-Operative & CC Interfacility Transfer*

CLINICAL INDICATIONS:

- Patient at outlying MTF requiring transfer to higher role of care for more definitive surgery/treatment

PRE-TRANSFER Patient Status Requirements:

a. JTS CPG – Intra-theater Transfer and Transport – recommends clinical parameters that should be met prior to transfer; if parameters are not met, they should be addressed and en-route mitigation plans formulated BEFORE departure / transfer:
   1) Heart rate 50><120 bpm
   2) SBP 70-80mmHg, MAP >60mmHg (permissive hypotension)
   3) If elevated ICP or CPP, maintain MAP 80><110mmHg, SBP 110><160mmHg
   4) Hematocrit >24% (or Hgb >8g/dL)
   5) Platelet count >50/mm^3
   6) INR <2.0
   7) pH >7.3
   8) Base deficit <5mEq/L
   9) Temperature >35.5ºC or 96ºF
   10) $ETCO_2$ 35><45, SPO_2 ≥92%, and/or $PaCO_2$ 35><45mmHg

If these criteria are not met, the transferring physician should continue resuscitation or provide documentation indicating limitations that compel urgent transfer. This can be documented in the comments section of the Standard Order Set for Critical Care Transfers document.

b. The four *MINIMUM* requirements which will be met prior to patient transfer are hemorrhage control, adequate shock resuscitation (SBP 70-80 mmHg, MAP >60 mmHg, UOP >0.5 mL/kg/hr, and/or BD <2, Temp >97ºF and <100ºF), stabilization of fractures, and initial post-operative recovery.
c. Attempt to keep patient packaging time at <25 minutes; use of warming devices in accordance with the JTS Hypothermia Prevention CPG.
d. Movement of Deceased Patients:
   1) In general, patients who meet clinical criteria for death are not to be transported by MEDEVAC, with the exception of extreme extenuating circumstances, such as emergency exfiltration during CSAR.
   2) If vital signs are absent prior to launch, make all reasonable attempts to resuscitate as clinical and tactical circumstances permit. If unsuccessful, consider basic cardiac ultrasound (as available) to determine whether any signs of cardiac activity are present. If absent, mission abort is warranted.

3) In such circumstances, contact and consultation with medical control or other available physician is suggested, in order to facilitate field determination of death and cessation of resuscitative efforts.

PROCEDURE:

a. **Role 2/3 provider responsibilities:**

It is the **responsibility of the transferring physician to write enroute care orders** appropriate for the transport environment and individualized for each patient in consultation with the Critical Care Flight Paramedic and/or the ECCN (or attending Flight Provider) prior to launch. The Flight Paramedic / Provider should be given a Standard Order Set for Critical Care Transfers or similar document with en route care orders signed by the transferring physician.

1) Provide a complete report to Flight Paramedic / Provider.
2) Provide all patient-specific related medical records.
3) Assist Flight Paramedic / Provider with packaging patient for transport as requested.
4) Complete specified areas on the appropriate patient care report
   i. Administrative data
   ii. Most current laboratory data
   iii. Mechanism of Injury (MOI)
   iv. Diagnosis
   v. Procedures
5) Place patient on ventilator at least 30 minutes prior to flight. Obtain pre-flight ABG to ensure patient tolerates ventilator settings.
6) It is strongly suggested that the transferring physician make every possible attempt to contact and discuss the case with the receiving physician or facility representative. Flight Paramedics and ECCNs should confirm or encourage this vital "physician-to-physician hand-off" if practicable.

b. **FLIGHT PARAMEDIC / PROVIDER responsibilities prior to transfer:**

1) Obtain orders for en route care from transferring physician; review orders and discuss potential en route problems with transferring physician, reconcile medications (ensure needed medications, specific to patient's condition, are obtained and prepared), allergies and patient's weight, confirm patient's identification, and secure personal effects.
2) Perform primary & secondary assessment ensuring an understanding of the patient's injuries / illness / procedures performed.
3) Spinal immobilization is indicated during transfer if ordered by transferring physician.
4) Assess placement and secure all tubes, lines, and drains & ensure proper functioning.
5) Ensure endotracheal tube is secure; secure pulse oximeter / $ETCO_2$ monitor.

6) Review ABG – ABG should be done within 30 minutes of flight; patient should be on transport ventilator with vent settings for transport; ABG obtained 15 minutes after being placed on transport ventilator.
7) Ensure vascular access X 2 - peripheral, central or IO and A-line as needed.
8) Check all bandages, splints, dressing, fixation devices and tourniquets for placement and ensure no evidence of ongoing hemorrhage.
9) If indicated, insert OG/NG tube for gastric decompression, especially in intubated patients; cap or place to suction.
10) Empty Foley catheter bag prior to flight; ensure UOP documentation by transferring facility.
11) For an intubated patient, provide adequate analgesia and sedation PRIOR to giving additional paralytic medications. Re-dose medications as needed prior to flight in accordance with transferring physician's orders.
12) Continue administration of blood products if ordered by transferring physician. If anticipated administration of blood products enroute, Flight Paramedic/Provider should request orders for blood products and appropriate blood products from the transferring physician and use FDA approved fluid warming device as appropriate for warming fluids.
13) Collect all patient care documentation for transport with patient, i.e. pre-hospital, transport, labs, x-rays, transferring facility notes, etc.
14) Remove all air from IV fluid bags and place all free flowing bags in pressure bags.
15) Ensure patient is properly packaged in a warming device unless contraindicated prior to transfer. Follow directions specific to each warming device ensuring over heating or thermal burns do not occur. Hypothermia, acidosis and coagulopathy constitute the "triad of death" in trauma patients.
16) Securely affix all equipment, supplies, loose tubing and lines to NATO litter prior to moving the patient to the vehicle or aircraft.
17) Once patient is packaged, ensure all lines are leveled and monitors are zeroed.
18) Provide eye and ear protection to patient.

Special considerations:

1) Eye Trauma: Fox shields should be placed for any patient with a suspected or confirmed open globe, possible intraocular foreign body or eye injury. Avoid placing dressing under the Fox shield and manipulation of the injured eye. Both the injured and uninjured eye should be covered IOT avoid excessive movement of the injured eye which may result from involuntary convergence. Also want to avoid nausea/vomiting in these patients. (JTTS CPG - Initial Care of Ocular & Adnexal Injuries)
2) Compartment Syndrome: Patients with extremity injuries, abdominal injuries/surgery, burns, coagulopathy and those who have received massive transfusion are at risk for compartment syndrome. Ensure proper assessment prior to flight. If compartment syndrome is suspected during flight, place extremity at the level of the heart. Pain out of proportion to the injury and paresthesia are symptoms

of compartment syndrome, as well as pallor, paralysis, pulselessness, and poikilothermia. Patients who are sedated, paralyzed or have an epidural or block in place are at increased risk and require judicious hands on assessment of at risk abdomen and extremities. (JTTS CPG – Compartment Syndrome and Fasciotomy)

3) Burns: For patients with partial and/or full-thickness burns to > 20% TBSA, use of the Burn Patient Admission Orders and JTTS Burn Resuscitation Flow Sheet are REQUIRED and should be continued during transfer to another facility. (JTTS CPG – Burn)
4) Advanced pain management modalities: For patients with epidurals, continuous peripheral nerve blocks, PCA infusions, or other pain medicine infusions, a pain note should be completed prior to transport as it is a vital part of provider communication. (JTTS CPG – Management of Pain, Anxiety and Delirium in Injured Warfighters)
5) Sedation and pain management must be maintained at appropriate levels throughout transport. As appropriate and as directed by transferring physician, attempt to maintain sedation target as follows using the Riker Sedation-Agitation Scale (SAS)

Post-Operative & CC Interfacility Transfer

Riker Sedation-Agitation Scale (SAS): Used as sedation target goal for Post Surgical / CC

- Non-intubated patients, provide sedation as needed to maintain a goal SAS Score of 3-4.
- Intubated patients, provided sedation as needed to maintain a goal SAS Score of 1-2.

		Definition
7	Dangerous agitation	Pulling at endotracheal tube, trying to remove catheters, climbing over bedrail, striking at staff, thrashing from side-to-side
6	Very agitated	Does not calm despite frequent verbal reminding of limits, requires physical restraints, biting endotracheal tube
5	Agitated	Anxious or physically agitated, attempting to sit up, calms down on verbal instructions
4	Calm, cooperative	Calm, arousals easily, follows commands
3	Sedated	Difficult to arouse, awakens to verbal stimuli or gentle shaking but drifts off again, follows simple commands
2	Very sedated	Arouses to physical stimuli but does not communicate or follow commands, may move spontaneously
1	Unarousable	Minimal or no response to noxious stimuli, does not communicate or follow commands

ECC Nurse Protocols May 2012

d. Patient Care Enroute to the Receiving Hospital

1) Patient vital signs will be monitored continuously enroute and documented at least every 5 – 15 minutes per transferring physician's orders.
2) Reassess patient at least every 15 minutes and address events as necessary following transferring physician's orders and protocols for the specific illness or injury.
3) Assess pain control, sedation and need for paralysis. Re-dose medications as needed in accordance with transferring physician's orders. Ideally, paralytic medication should not be administered near the end of the flight. Significant, adjunctive analgesia may be required to compensate for initial lift, landing and in flight combat maneuvers, therefore Flight Paramedic/Provider should consider carrying higher volumes of analgesia that would be normally used in ground transport or fixed facilities.
4) All events will be addressed with appropriate interventions according to transferring physician's orders and protocols. All interventions require reassessment for patient response to the intervention.
5) All enroute care, including ventilator changes, medications, events, interventions, and patient's response will be documented on the appropriate patient care documentation.

e. Patient Report and Transfer of Care at the Receiving Hospital

1) A verbal and written patient report will be given to the receiving nurse or physician upon delivery of the patient.
2) Routinely, the responsibility of care will be transferred at the receiving ED. On rare occasions (i.e. mass casualty incidents, pending emergency flights, etc.), care may need to be transferred on the helipad rather than at the bedside.

Post-Operative & CC Interfacility Transfer

3) For Tail-to-Tail transfers, the Flight Paramedic/Provider initiating transport will send all documentation from the transferring facility and the patient care documentation from the first leg of the flight with the Flight Paramedic/Provider completing the second leg of the transfer. The Flight Paramedic/Provider completing the second leg of the transfer will initiate their own patient care documentation, circling "2nd Leg" at the top of the form and ensure all documentation is turned over to the MTF upon arrival and hand off of patient care.
4) The patient care documentation will be completed and left with the patient at the receiving facility at the time of patient handover. If unable to complete documentation due to extensive mission requirements, the patient care documentation will be forwarded to the appropriate medical information receiving facility/person IAW local / theater policy.

Any in-flight problems should be addressed per appropriate protocol and per written instruction from transferring physician. Continued problems should prompt contacting medical control as soon as it is possible.

Document procedure, results, and vital signs.

III. ADULT PATIENT CARE PROTOCOLS

26. ***Rapid Sequence Induction-RSI***

A. Objectives:

1) To facilitate airway management through the use of sedatives and paralytics.

B. General Information:

1) Patients presenting or have the potential for severe airway compromise require sedatives and paralytics to secure the airway.

2) Patients with the following should be considered for RSI:
- Burns to the face with suspected inhalation injury
- Severe trauma to the face that may occlude airway
- Patients who must have prolonged ventilator assistance
- GCS less than 8, with associated TBI or Head injury

C. Warnings/Alerts:

1) This procedure shall be done with at least 2 providers. Divide the work load- ventilate, suction, cricoid pressure, drugs, and intubation

2) Shall use end-tidal CO2 monitors and SpO_2 monitoring. Suspected TBI/Head trauma patients end-tidal CO2 shall be kept between 35-40 mmHg.

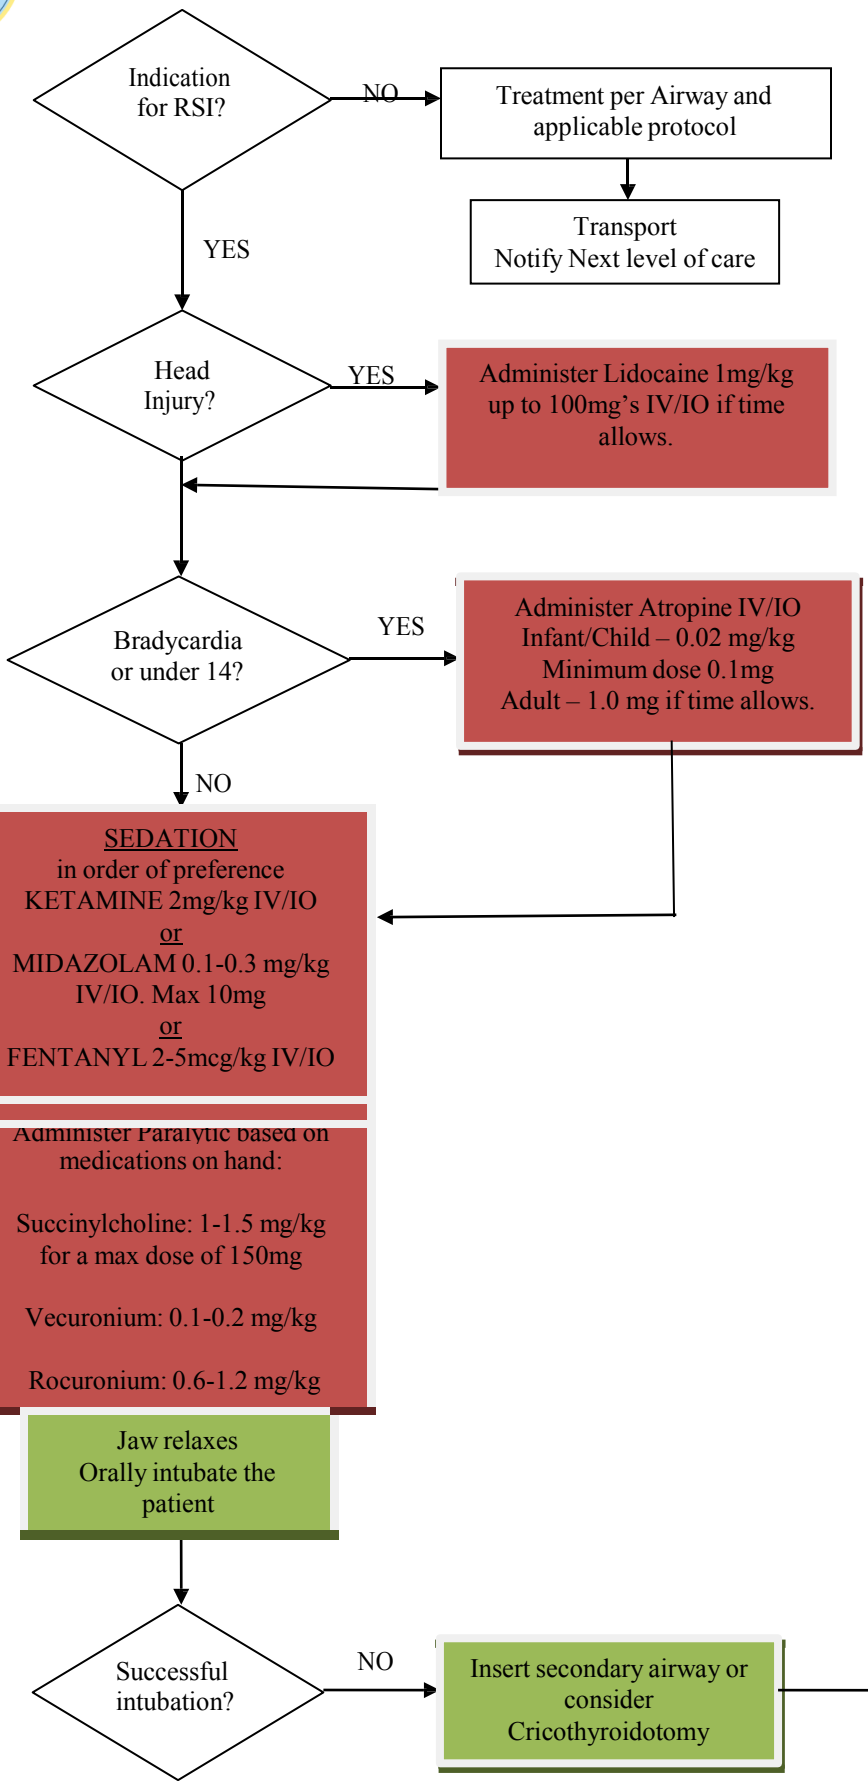
3) Protect the patient from self-extubation.

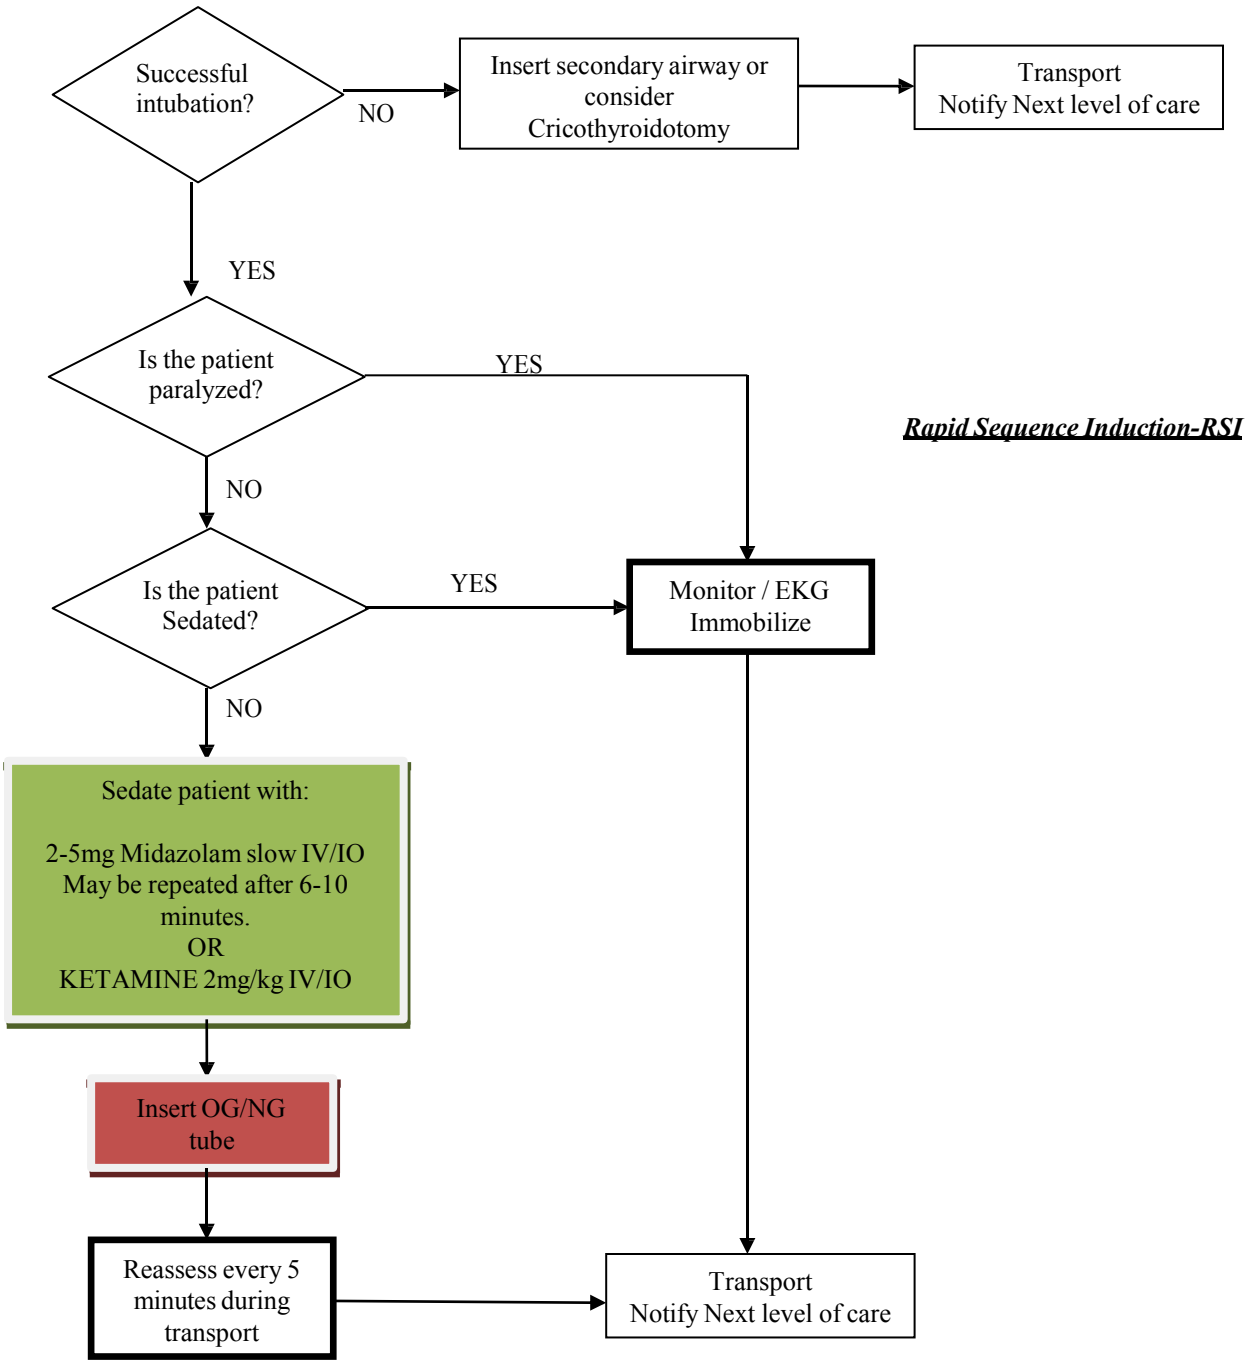
4) Do not administer Succinylcholine to patients with a HX of Malignant Hyperthermia.

5) Administration of analgesics is required on patients requiring advanced airway procedures.

6)

Rapid Sequence Induction-RSI





Rapid Sequence Induction-RSI

PAGE INTENTIONALLY

LEFT BLANK

III. ADULT PATIENT CARE PROTOCOLS

27. ***Seizures***

A. Objectives:

1) To assess and treat patients with seizures.

2) To protect the airway of a seizing patient.

B. General Information:

1) Medications shall only be given to patients having active seizure lasting greater than 2 minutes.

2) All patients who receive Ativan, Valium, and Versed shall have cardiac and SpO_2 monitoring.

3) - Ativan (Lorazepam) is the preferred drug for seizures.
Dilute in equal amount of NS before administration IV/IO
2mg slow push
Can be given IM/IN if no vascular access, do not dilute

- Versed (Midazolam)
2mg slow IV/IO push
Can be given IM/IN if no vascular access

- Valium (Diazepam)
Up to 5mg slow IV push IV/IO
Can be given IM/IN if no vascular access

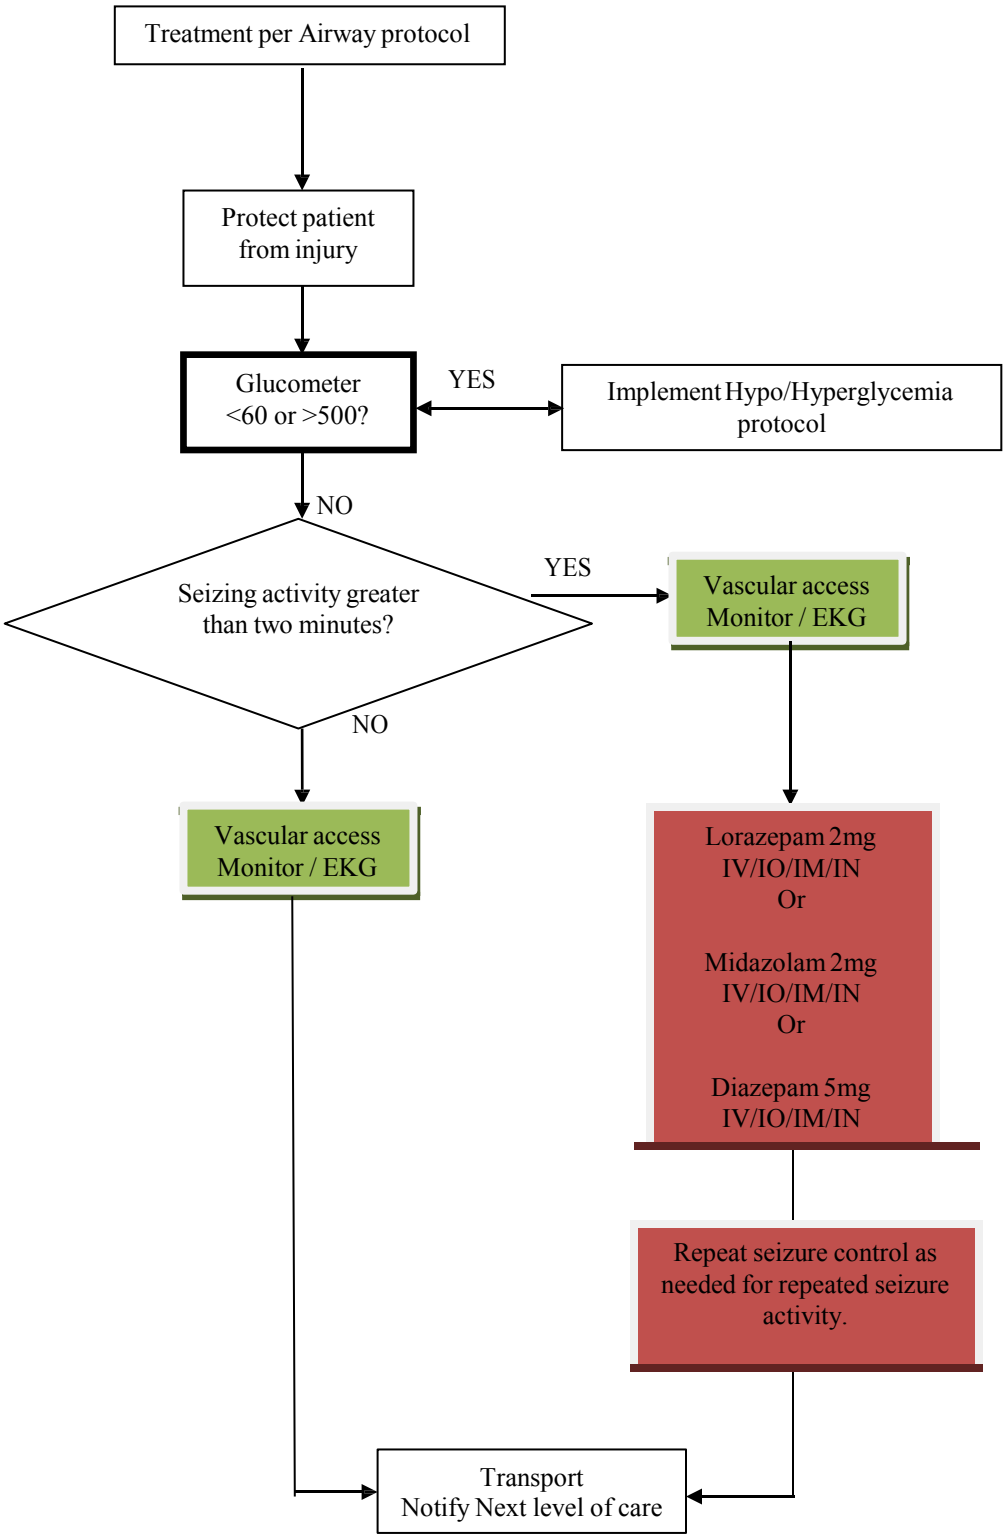
C. Warnings/Alerts:

1) Ativan, Valium, and Versed all have the potential to cause respiratory depression and bradycardia. Patients shall have continuous cardiac and SpO_2 monitoring.

2) Flush IV lines thoroughly after Valium administration. Valium is incompatible with most other medications.

3) After two attempts of controlling a seizure, seizure activity continuing, implement RSI protocol.

Seizures



Treatment per Airway protocol
Protect patient from injury
Glucometer <60 or >500?
YES
Implement Hypo/Hyperglycemia protocol
NO
Seizing activity greater than two minutes?
YES
Vascular access Monitor / EKG
NO
Vascular access Monitor / EKG
Lorazepam 2mg IV/IO/IM/IN Or
Midazolam 2mg IV/IO/IM/IN Or
Diazepam 5mg IV/IO/IM/IN
Repeat seizure control as needed for repeated seizure activity.
Transport Notify Next level of care

III. ADULT PATIENT CARE PROTOCOLS

28. ***Shock***

A. Objectives:

1) To assess and treat patients with tissue perfusion.

B. General Information:

1) Types of shock:
- Hypovolemic: Hemorrhage / Fluid loss
- Cardiogenic (Pump failure)
- Distributive (Sepsis)
- Obstructive (Tension Pneumo)

2) All patients being treated for shock shall be given a blanket or hypothermia prevention kit.

3) Optimize Hemostasis: Fluid resuscitation in;

- Hemorrhagic trauma with NO significant head injury should follow permissive hypotensive resuscitation guidelines (PHRG) maintaining MAP 60, but not raising the BP into the "normal" range, which may increase bleeding. Only give minimal "bolus" appropriate resultative fluid per JTS CPG to **maintain MAP >60, NIBP Systolic BP >90 , palpable Radial pulse (Femoral pulse preferred), (if NIRS device available, STO_2 >70%) and/or change in mental status.**

- Hemorrhagic trauma WITH significant head injury should NOT follow permissive hypotension guidelines. **Maintain NIBP Systolic BP 110><160 and MAP 80><110.**

- Calcium shall be administered on all trauma patients with suspected internal bleeding or hypovolemic shock, as is directly helps with clotting factors. This may be given in conjunction with TXA and blood products, however if only one IV/IO access is present do not delay the administration of blood products.

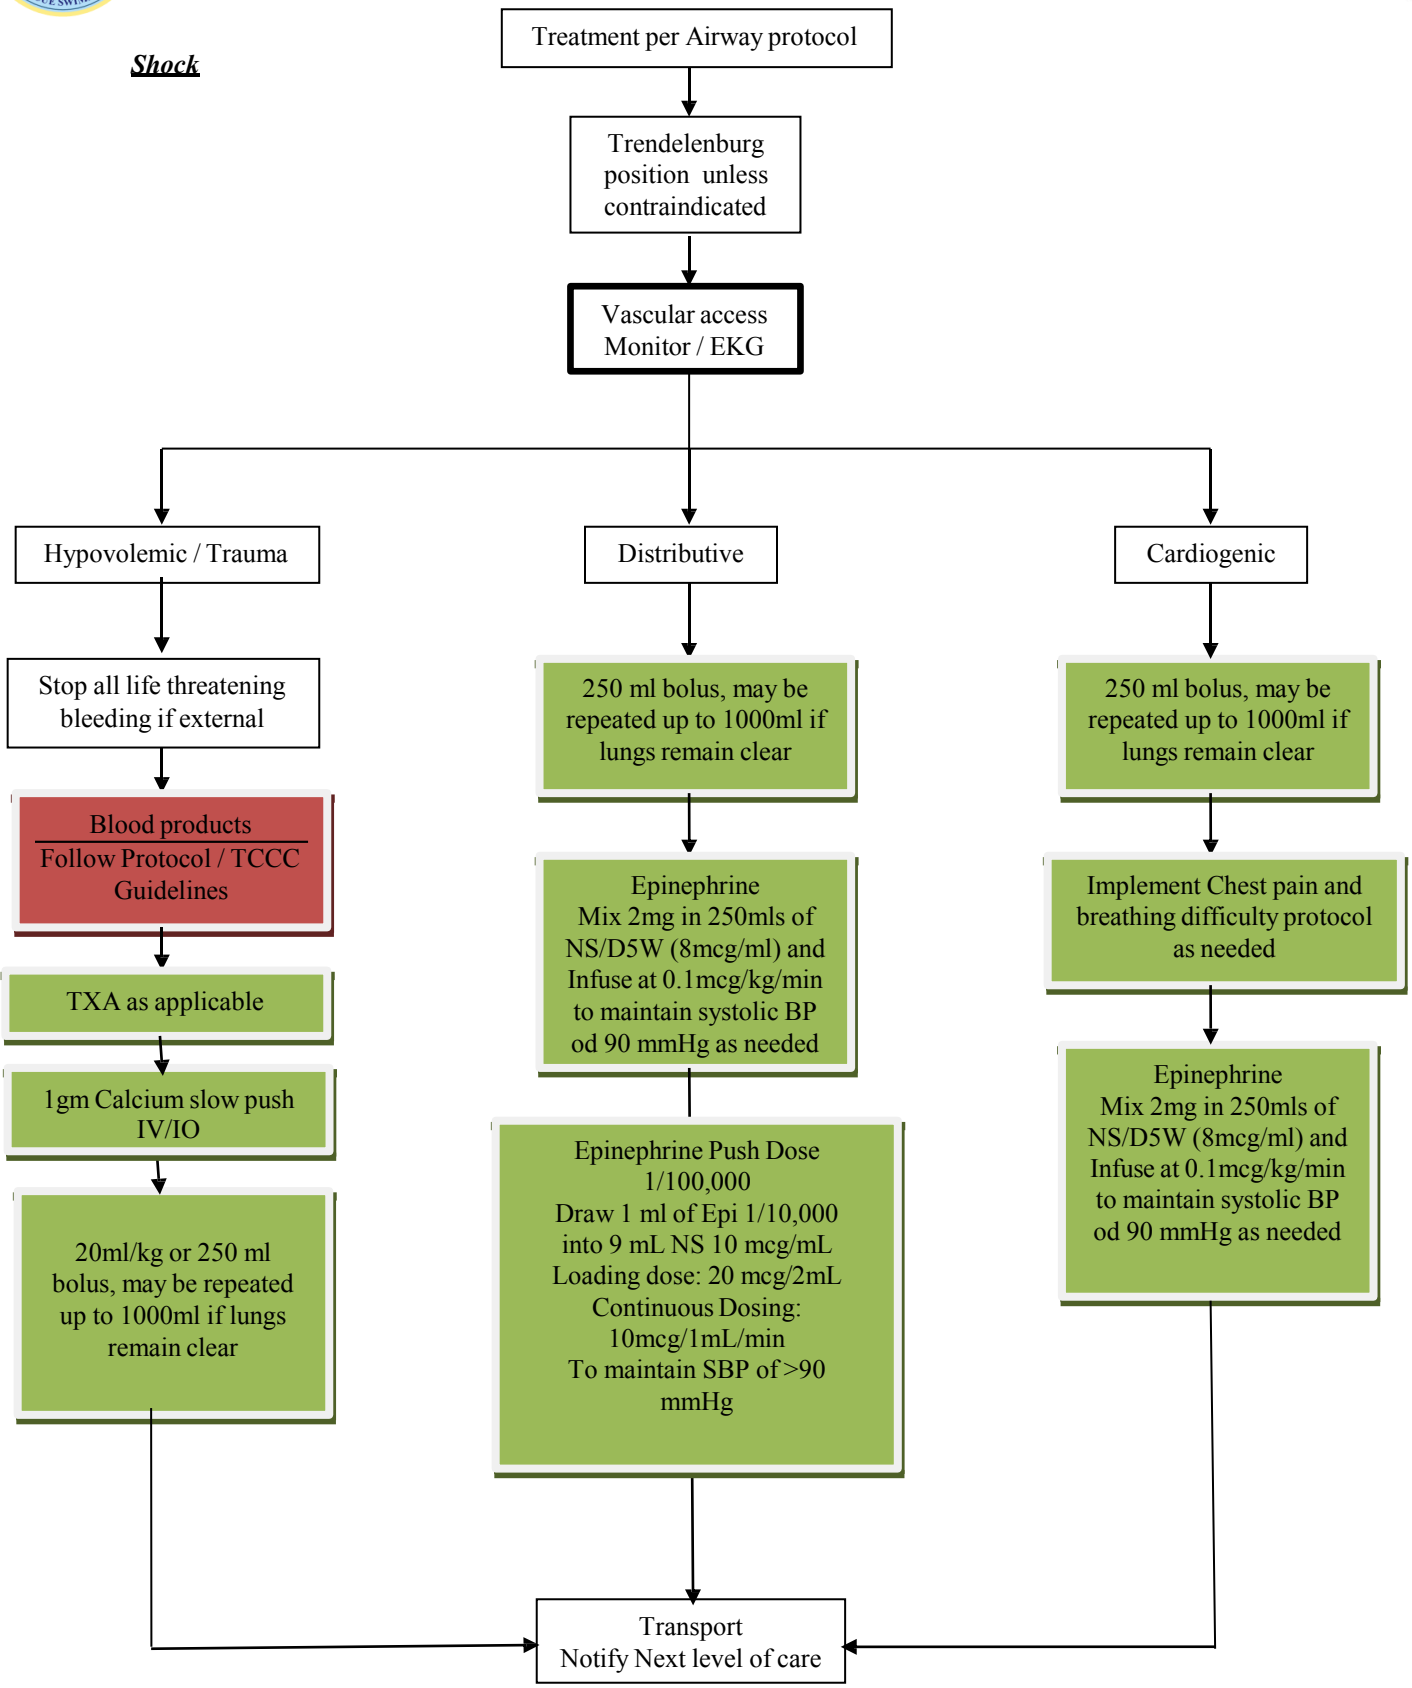
C. Warnings/Alerts:

1) Avoid Pressors as able (use as LAST RESORT in TRAUMA) – Always continue IVFs: Optimize hemostasis and correct volume loss.

D. Notes:

1) The goal of hypovolemic shock management is to prevent the lethal triad of hypothermia, acidosis, and coagulopathy.

Shock



Treatment per Airway protocol
Trendelenburg position unless contraindicated
Vascular access Monitor / EKG
Hypovolemic / Trauma
Distributive
Cardiogenic
Stop all life threatening bleeding if external
Blood products
Follow Protocol / TCCC Guidelines
TXA as applicable
1gm Calcium slow push IV/IO
20ml/kg or 250 ml bolus, may be repeated up to 1000ml if lungs remain clear
250 ml bolus, may be repeated up to 1000ml if lungs remain clear
Epinephrine
Mix 2mg in 250mls of NS/D5W (8mcg/ml) and Infuse at 0.1mcg/kg/min to maintain systolic BP od 90 mmHg as needed
Epinephrine Push Dose 1/100,000
Draw 1 ml of Epi 1/10,000 into 9 mL NS 10 mcg/mL
Loading dose: 20 mcg/2mL
Continuous Dosing: 10mcg/1mL/min
To maintain SBP of >90 mmHg
250 ml bolus, may be repeated up to 1000ml if lungs remain clear
Implement Chest pain and breathing difficulty protocol as needed
Epinephrine
Mix 2mg in 250mls of NS/D5W (8mcg/ml) and Infuse at 0.1mcg/kg/min to maintain systolic BP od 90 mmHg as needed
Transport
Notify Next level of care

III. ADULT PATIENT CARE PROTOCOLS

29. ***Needle Chest Decompression/Thoracostomy-finger or tube***

A. Objectives:

1) To provide guidance for how and when providers should perform needle decompression.

2) Insertion of a chest tube is an advanced level practice to be performed only by those providers certified as FP-C, TP-C, or RN and above.

B. General Information:

1) Management of Tension Pneumothorax and or Massive Hemothorax requires chest decompression.

2) Needle decompression is the primary relief of a Tension Pneumothorax pre-hospital.
- Midclavicular – 2nd intercostal space
- Anterior axillary – 5th intercostal space

3) After needle decompression a chest seal or occlusive dressing shall be placed over site to prevent sucking chest wound.

4) If needle decompression is ineffective, prolonged transport time or distance expected, or in the presence of massive barotrauma, a chest tube or finger thoracostomy may be the most effective for maintaining chest decompression.
- Incision site: Affected side, anterior axillary- 5th intercostal space

5) Consider pain management/sedation prior to procedure. Do not delay treatment for sedation.

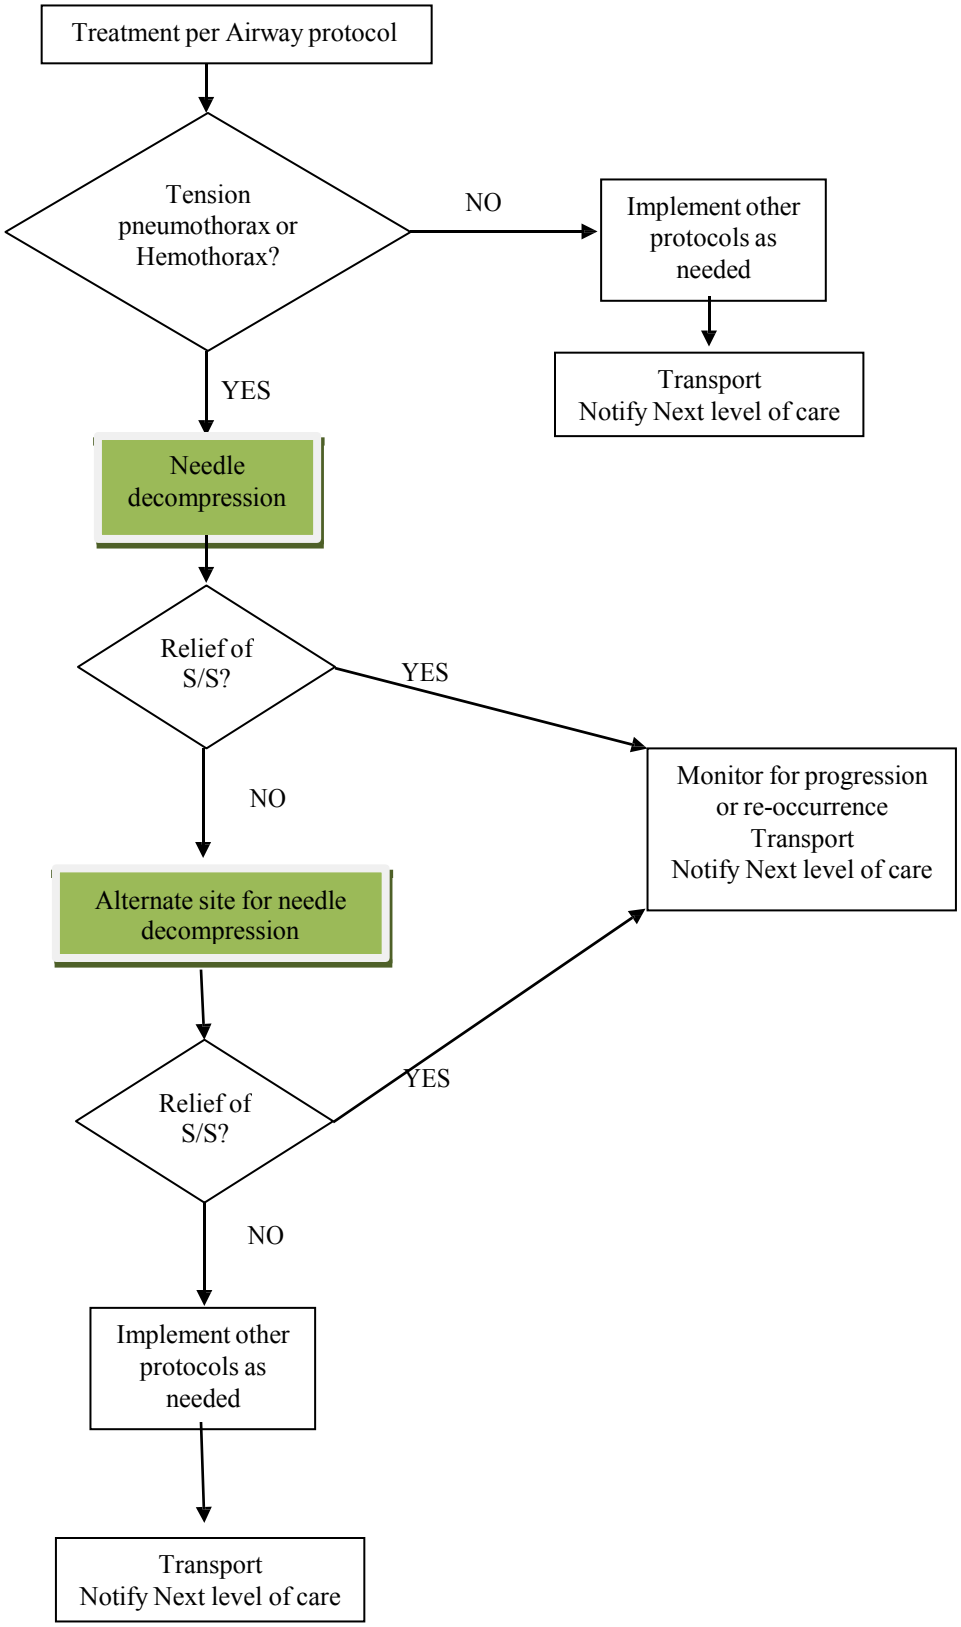
C. Warnings/Alerts:

1) Larger patients may require multiple needle decompressions or alternate anterior axillary site.

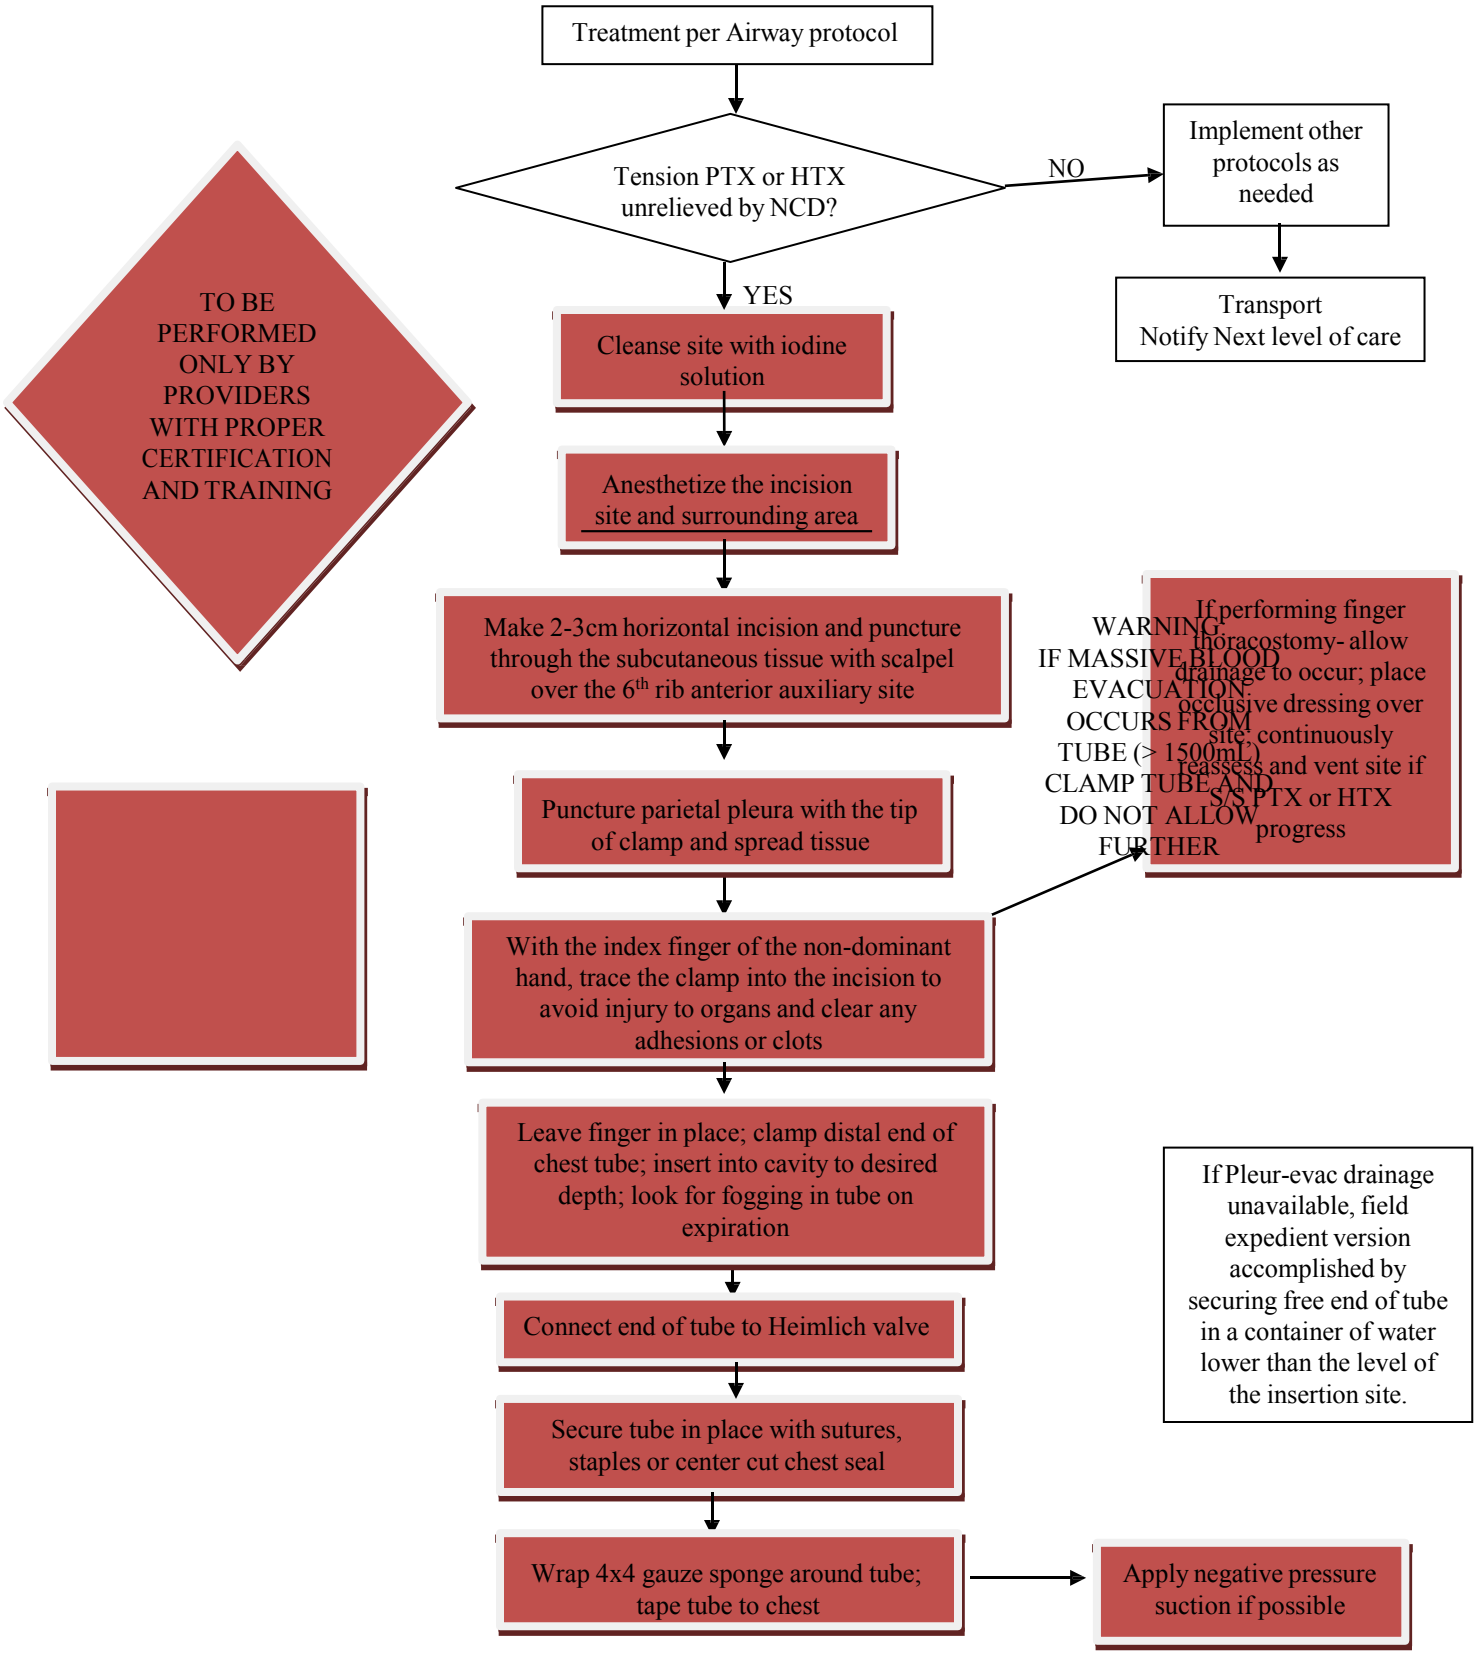
2) Do not insert any needle/tube/finger medial to the Anterior axillary line as there is risk to damage the great vessels and impact the myocardium.

3) Avoid Needle decompression in patients that are hemodynamically stable.

Needle Chest Decompression



Chest Tube Insertion/Finger Thoracostomy



Treatment per Airway protocol
Tension PTX or HTX unrelieved by NCD?
NO
Implement other protocols as needed
Transport
Notify Next level of care
YES
TO BE PERFORMED ONLY BY PROVIDERS WITH PROPER CERTIFICATION AND TRAINING
Cleanse site with iodine solution
Anesthetize the incision site and surrounding area
Make 2-3cm horizontal incision and puncture through the subcutaneous tissue with scalpel over the 6th rib anterior auxiliary site
Puncture parietal pleura with the tip of clamp and spread tissue
With the index finger of the non-dominant hand, trace the clamp into the incision to avoid injury to organs and clear any adhesions or clots
WARNING:
IF MASSIVE BLOOD EVACUATION OCCURS FROM TUBE (> 1500mL) CLAMP TUBE AND DO NOT ALLOW FURTHER
If performing finger thoracostomy- allow drainage to occur; place occlusive dressing over site; continuously reassess and vent site if S/S PTX or HTX progress
Leave finger in place; clamp distal end of chest tube; insert into cavity to desired depth; look for fogging in tube on expiration
Connect end of tube to Heimlich valve
Secure tube in place with sutures, staples or center cut chest seal
Wrap 4x4 gauze sponge around tube; tape tube to chest
Apply negative pressure suction if possible
If Pleur-evac drainage unavailable, field expedient version accomplished by securing free end of tube in a container of water lower than the level of the insertion site.

PAGE INTENTIONALLY

LEFT BLANK

III. ADULT PATIENT CARE PROTOCOLS

30. *Toxicological Emergencies (Overdose)*

A. Objectives:

1) To assess and treat patients who have a toxicological medical emergency.

B. General Information:

1) CNS depressants (Symptoms may include: respiratory depression, pinpoint pupils, bradycardia, and hypotension)
- Examples: Opiates, Benzodiazepines, Ethyl Alcohol

2) Hallucinogens (Symptoms may include: Hallucinations, Hypertension, and Tachycardia)
- Examples: LSD, Cannabis, PCP, Mushrooms, Ecstasy, Jimson Weed, Spice, Nutmeg

3) CNS stimulants (Symptoms may include: Hypertension, tachycardia, dysrhythmias)
- Examples: Cocaine, amphetamines, methamphetamines, Dexedrine, caffeine, ephedrine

4) Tricyclic Antidepressants (Symptoms may include: Altered mental status, seizure, depressed respirations, and coma)
- Examples: Amitrptyline (Elavil), Amoxapine (Asendin), Flexeril (Cyclobenzaprine), Imipramine (Trofanil), etc…

C. Warnings/Alerts:

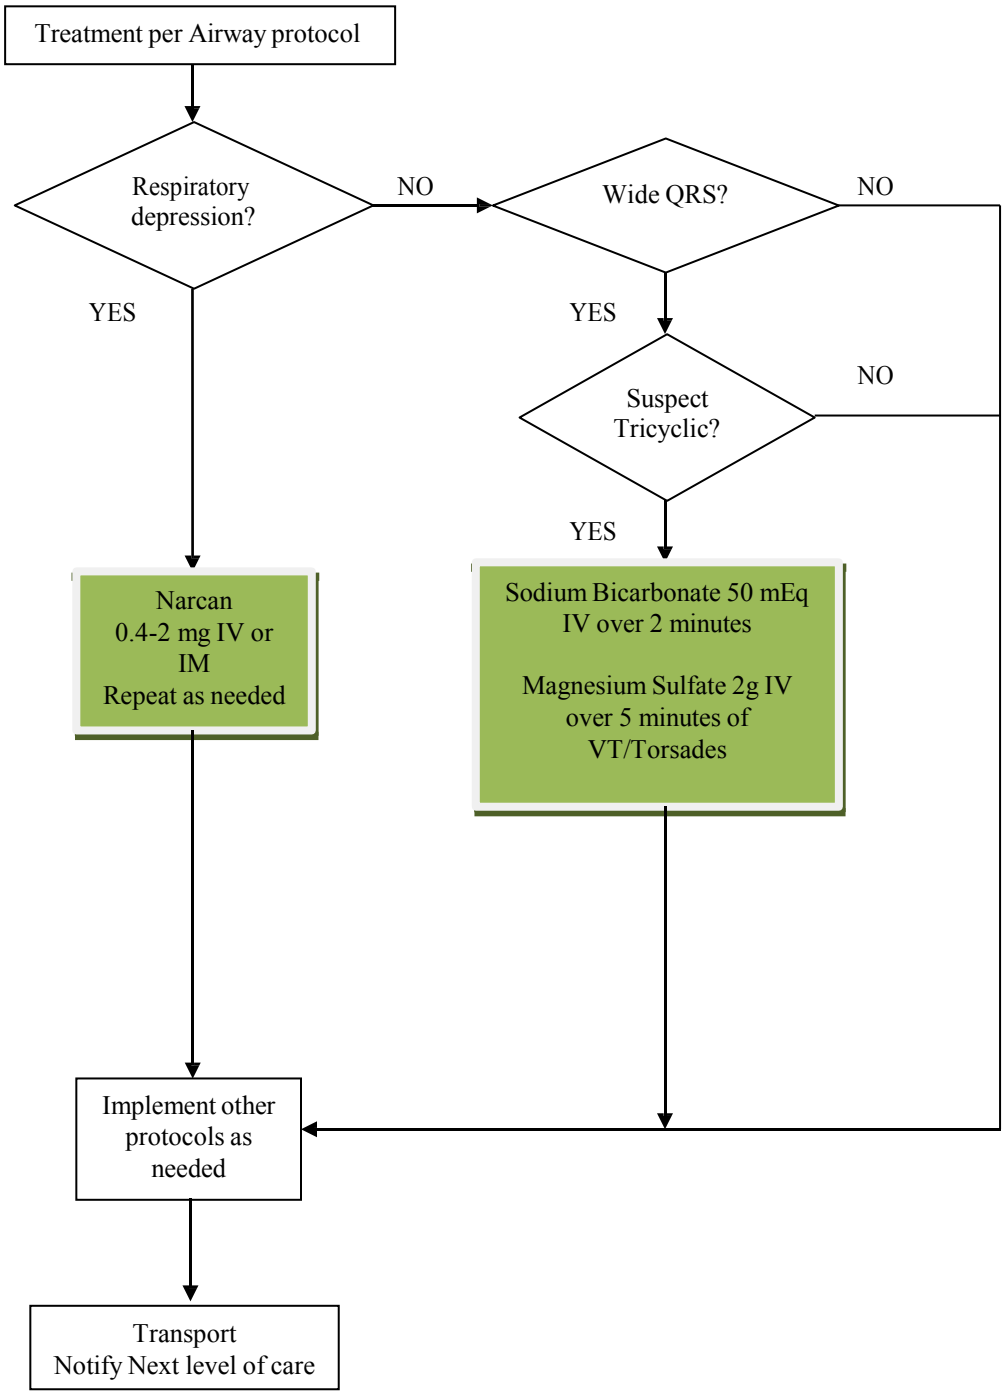
1) Narcan can precipitate seizures in patients with seizure HX or in long term narcotic addicts.

2) The goal of Narcan is to establish adequate respiratory rate and drive, not to return the patient to full consciousness.

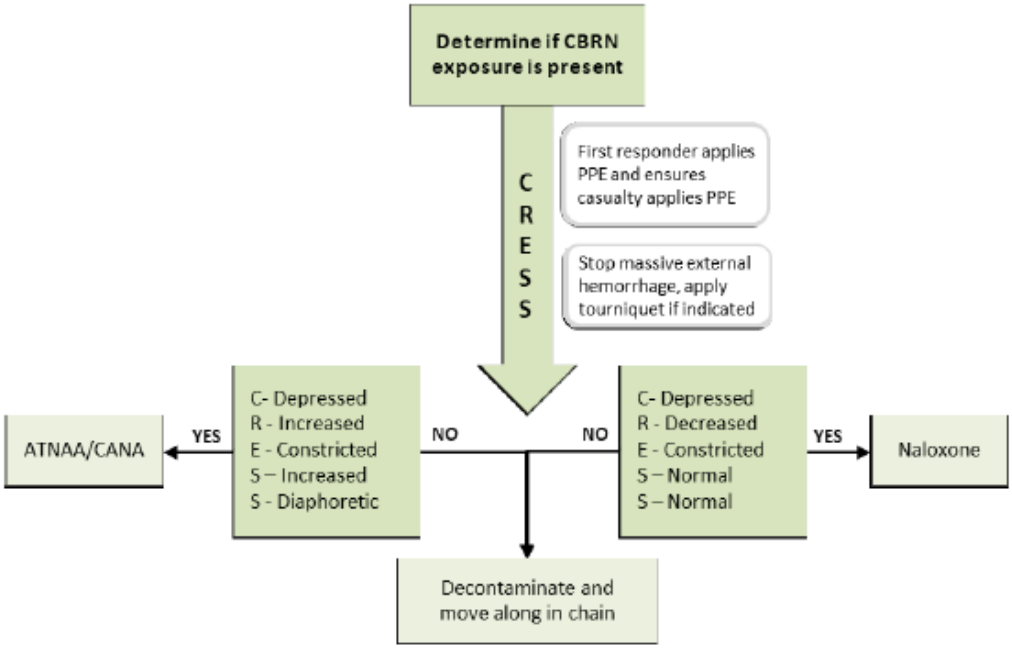
3) Narcan has a short half-life and may need to be repeatedly dosed until transfer of care is complete.

4) If at all possible, documentation or collection of medications suspected to be used by the patient should be transported.

Toxicological Emergencies (Overdose)



C	Consciousness (unconscious, seizures, depressed consciousness, agitation)
R	Respirations (present or absent, labored, increased or decreased)
E	Eyes (constricted, dilated, normal)
S	Secretions (dry, normal, increased)
S	Skin (diaphoretic, dry, hot, cyanosis)



Nerve agents: The signs and symptoms of nerve agent poisoning will depend on the dose and route of the exposure. In general, larger doses and direct inhalation of nerve agent vapor result in quicker onset and greater severity of effects. The most important effects of nerve agents are on the lungs, airway and the nervous system. Nerve agents exert their toxic effects by inhibiting or blocking the action of acetylcholinesterase (AChE), a critical enzyme. AChE is found in the plasma, red blood cells and nervous tissue. Although nerve agents will affect the enzyme in all three areas, it is the neurological effects which are the most important.

The mnemonic SLUDGE helps identify some of these findings:

- Salivation
- Lacrimation
- Urination
- Defecation
- Gastric
- Emptying

Key Measures in Resuscitating Nerve Agent Patients
• Secure the airway and provide positive pressure ventilation
• Administer atropine and 2-Pam-Chloride
• Administer Valium if supplied. Otherwise utilize Versed.
• Repeat atropine as needed

III. ADULT PATIENT CARE PROTOCOLS

31. *Trauma / Traumatic Arrest*

A. Objectives:

1) To appropriately assess and treat patients who have traumatic injuries.

B. General Information:

1) Control all life-threatening bleeding
- Direct pressure / wound packing
- If direct pressure does not work, Tourniquet if appropriate

2) Lifesaving interventions that may be performed pre-transport:
- Control of all Arterial or massive bleeding
- Emergency Cricothyroidotomy of an Obstructed Airway
- Needle decompression or Chest tube relief of a Tension Pneumothorax or massive Hemothorax. Chest tubes are indicated for long transports or no relief from needle decompressions.
- Stabilization of Pelvic injury with use of Pelvic sling device
- Management of a Flail Chest- positive pressure support or if indicated, Intubate and assist in ventilations as needed.

3) The goal of IV fluid administration is to maintain a systolic BP of >90 mmHg. Should be practiced with caution in cases of abdominal injuries.

4) For patients with head injuries and a GCS < 8, the goal of IV fluid administration is to maintain a systolic BP of >110 mmHg and establish a secure airway.

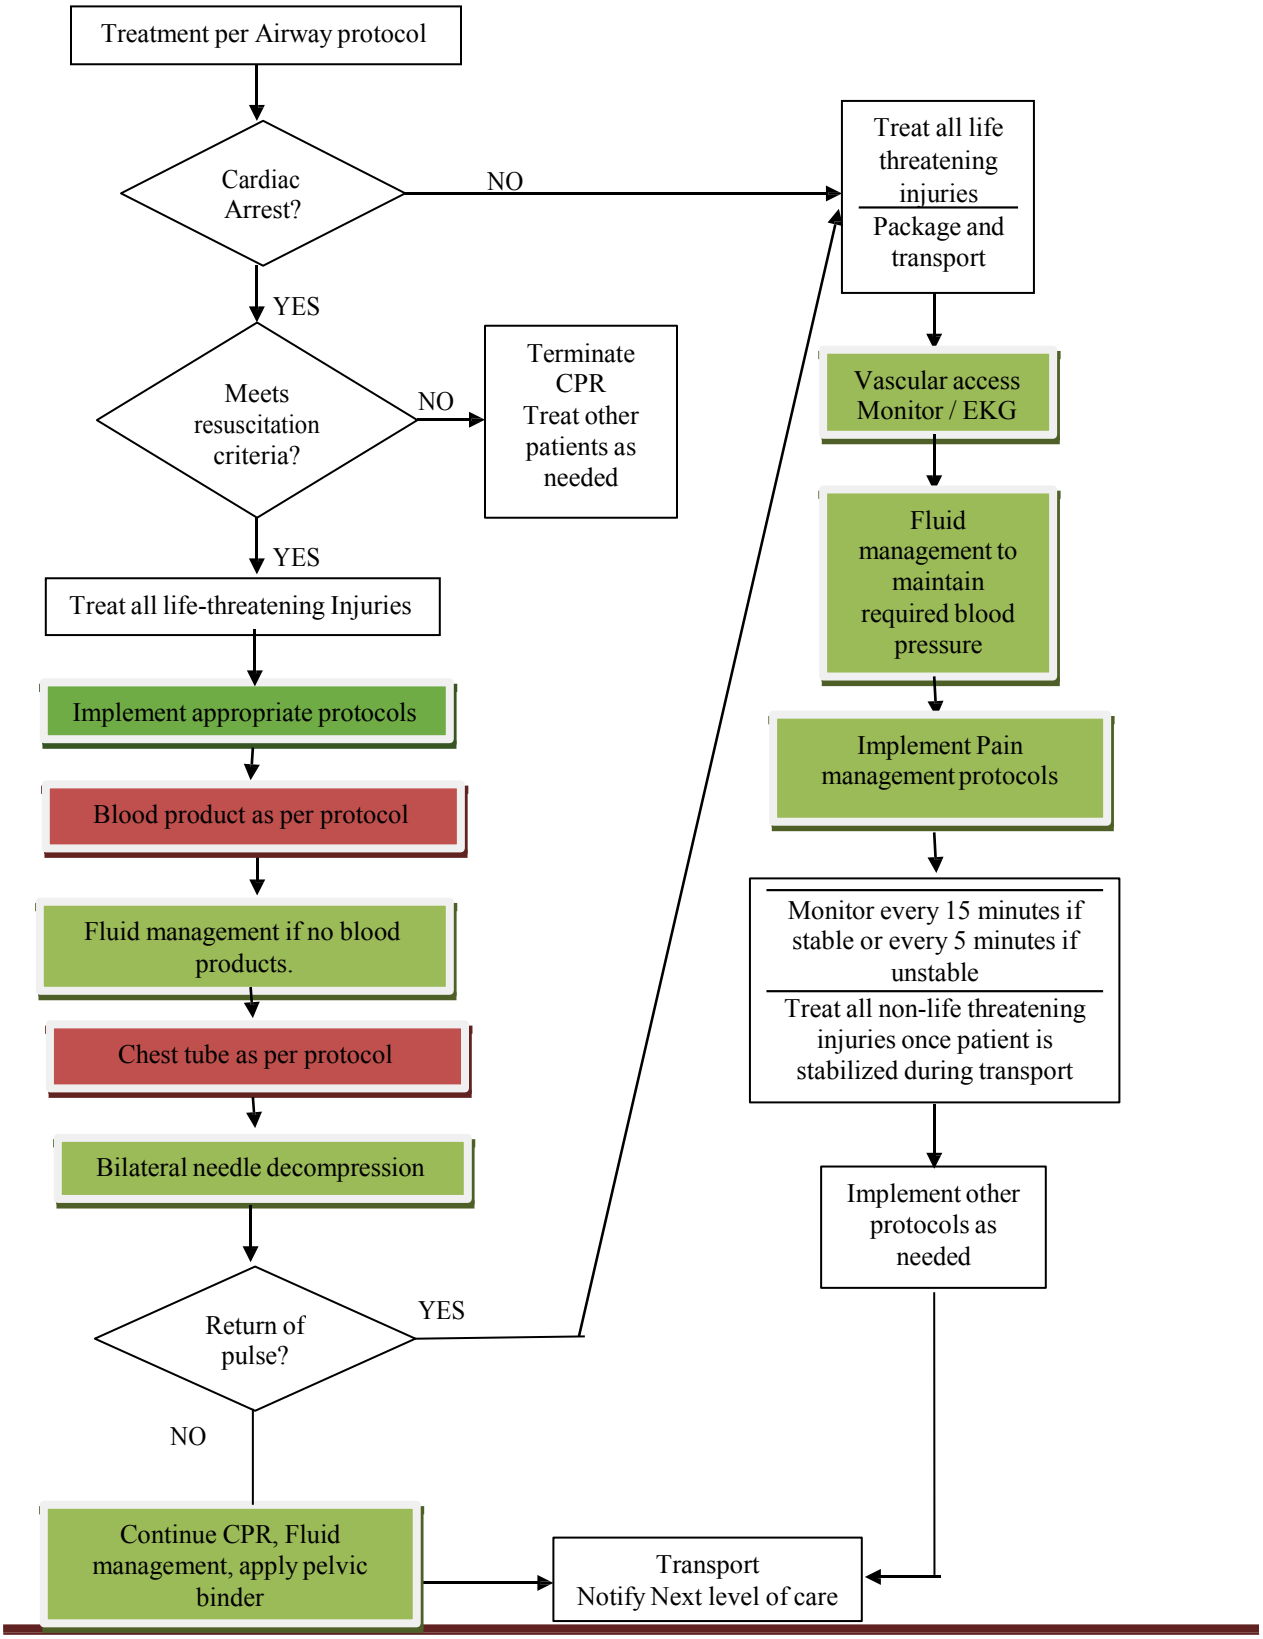
5) Trauma resuscitation Criteria:
- Should be discontinued if injuries are incompatible with life (rigor mortis, lividity, etc.)
- Mass casualty situation, patients with no breathing and pulse shall follow START algorithm.

6) All treatments to Trauma patients shall be in accordance with International Trauma Life Support guidelines (ITLS), Pre-Hospital Trauma Life Support (PHTLS), Tactical Combat Casualty Care Guidelines (TCCC), and/or Clinical Practice Guidelines (CPG's).

C. Warnings/Alerts:

1) Do not delay transport to perform NON-lifesaving interventions on scene.

Trauma / Traumatic Arrest



III. ADULT PATIENT CARE PROTOCOLS

32. *Vascular Access*

A. Objectives

1) To provide guidance for how and when providers should obtain vascular access.

B. General Information:

1) Fluid management standing orders for hyperprofusion:
- Adults: 250mL bolus with reassessment up to 1000mL

2) All bolus medications shall be followed by an appropriate flush, 20-30ml.

3) Site selection for peripheral access shall start distally in the extremities.

4) Indications for Intraosseous access:
- Cardiac arrest
- Profound hypovolemia
- Patients's with immediate need for medications or fluids.

5) IO's shall be flushed prior to administering any fluid/medications into the site.

6) IO approved sites:
- Sternal (F.A.S.T 1 Device only)
- Proximal Tibia – 1-2 finger width medial to the tuberosity
- Proximal Humerus – Directly in the greater tubercle (Lateral, upper aspect of the humerus)

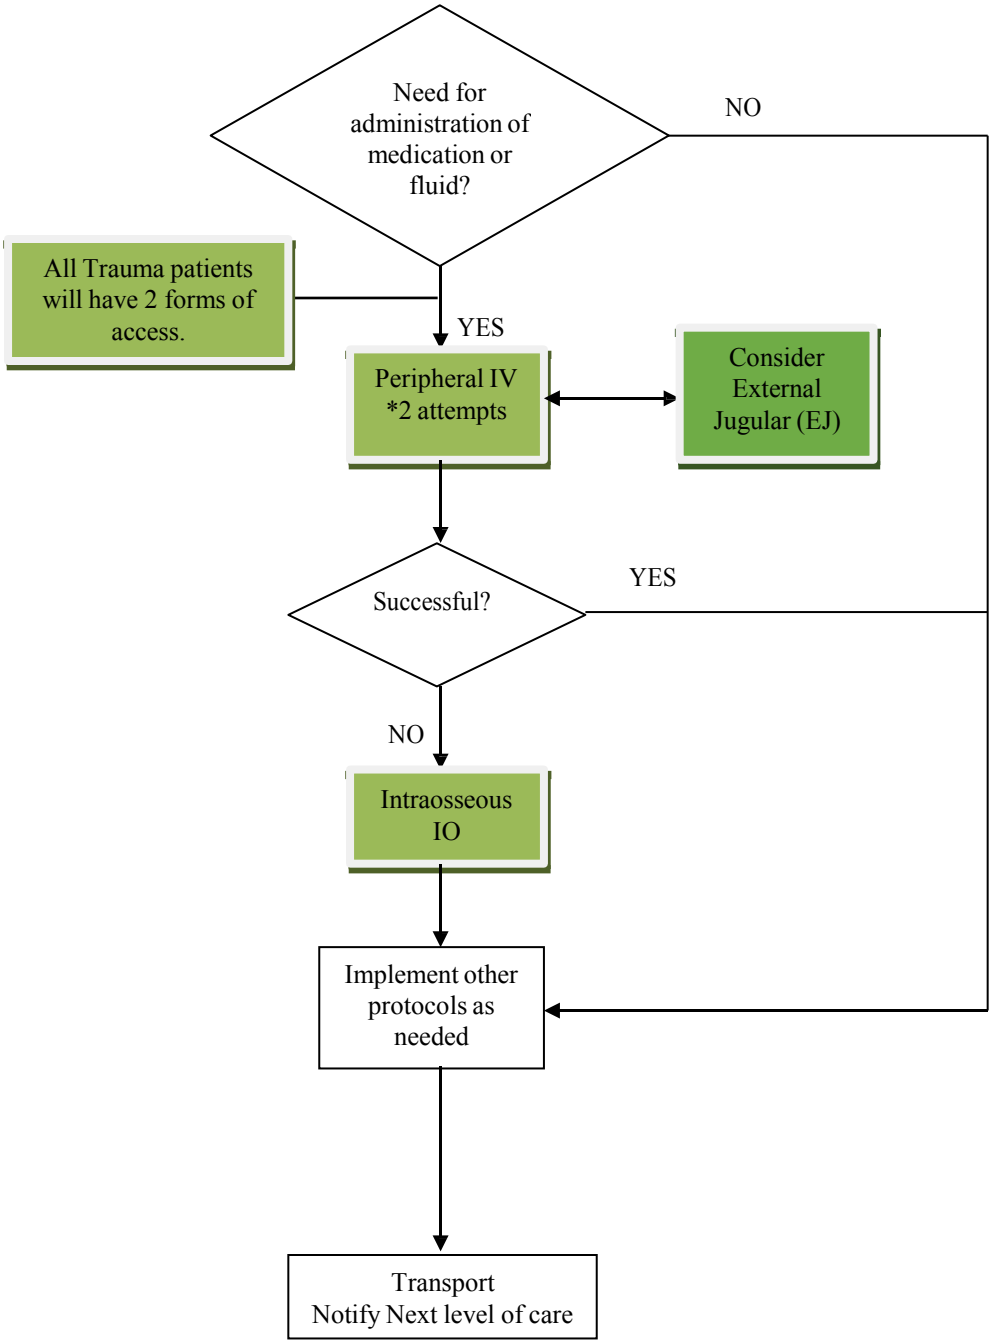
C. Warnings/Alerts:

1) Do not use a 14g or above needle for IV use.

2) Failure to properly flush after administration of an IO will result in poor or occluded flow.

3) Caution in placement of External Jugular (EJ) due to increased improper placement.

Vascular Access



III. ADULT PATIENT CARE PROTOCOLS

33. ***Ventilator Management***

VENTILATOR MANAGMENT

CLINICAL INDICATIONS:

- Patient received from transferring facility, intubated, and requires ventilator support.
- Patient requiring intubation in the field and subsequent respiratory support.

CONTRAINDICATIONS:

- Equipment malfunction / failure.

PROCEDURE:

- Turn on ventilator and ensure that machine is functional and battery is charged.
- Attach ventilator tubing and O_2 tubing to machine.
- If patient is a transfer and already on vent, maintain ventilator settings from medical treatment facility.
- **If patient "newly" on ventilator, initial settings should include:**
  - **Mode: AC, SIMV, or ASV (if using Hamilton T1)**
  - **Rate: 10-16bpm (or adequate rate for pediatric patient)** (typical adult start rate is 12, then adjust PRN)
  - **FiO_2: 100 percent**
  - **I:E ratio: 1:2 – 1:4**
  - **Tidal Volume: 6-8mL/kg (of ideal body weight)**
  - **PEEP: 5**
- Monitor waveform on machine and patient to ensure not "breathe stacking" – if this occurs, a high-pressure alarm may sound. However, if breath stacking suspected even in absence of alarm – disconnect tubing and allow exhalation. Increase I:E.
- If at any time patient begins to desaturate or develop respiratory problems – check rapidly to ensure that vent did not fail and O_2 tank not empty. Immediately disconnect ventilator and ventilate patient with BVM and 100% O_2. If this resolves problem or vent failed, continue to bag patient. Then titrate FiO_2 down as much as possible while keeping O_2 sat >93% (Goal FiO_2 50-60%) in order to attempt to conserve oxygen for long flights and conserve battery power.
- If problem does not resolve, ensure tube did not move during transfer. If advanced – pull back to original length and attempt to bag. If this fails, ensure equal chest rise with breaths and that a tension pneumothorax has not developed (if chest tube in place, ensure it is functioning). If tension pneumothorax suspected, perform immediate needle thoracostomy.
- If tube has pulled farther out of trachea, DO NOT ATTEMPT TO ADVANCE IT without placement of bougie to verify tracheal placement. When advancing bougie to verify placement, feel for tracheal rings or carina stop. If in doubt, pull tube and attempt BVM. If this fixes problem, continue to bag patient.

Document procedure, results, and vital signs.

Simplified Automated Ventilator (SAVe)
Single tidal volume and respiratory rate (Vt = 600 mL; BPM 10)
6 Lpm of supplemental O_2 (MAX FiO_2 = 62%)

SAVEe II
Varied tidal volume based on patient height
Accepts supplemental O_2 (FiO_2 21 – 100%)

Terms

Volume-targeted modes (Examples: CMV, A/C, SIMV): Volume constant, inspiration terminates when preset V_t delivered. Peak airway pressure is variable and increases as needed to deliver prescribed V_t.

Pressure-targeted modes (Examples: PSV, PCV): Volume variable, terminates when preset pressure reached. Volume is variable. Peak airway pressure is fixed, determined by set pressure level.

Adaptive Support Ventilation (ASV): Only available on the Hamilton T1. ASV provides intelligent ventilation mode that continuously adjusts respiratory rate, tidal volume, and inspiratory time depending on the patient's lung mechanics and effort.

Tidal volume (V_t): The volume of gas, either inhaled or exhaled, during a breath and commonly expressed in milliliters. V_t is generally set between 6-10ml/kg IBW (ideal body weight), to prevent lung over-distension and barotrauma.

IBW calculation:
Men: [(height in inches – 60) x 2.2] + 50= Kg IBW
Women: [(height in inches – 60) x 2.2] + 45= Kg IBW

Ventilator Management

Minute Ventilation (V_E): The average volume of gas entering, or leaving, the lungs per minute, commonly expressed in liters per minute. The product of V_t and RR (respiratory rate). Normal V_E is 5 – 10 L/min.

Inspiratory (I) and Expiratory (E) time and I:E ratio: The speed at which the V_t is delivered. Setting a shorter inspiratory time (I) results in a faster inspiratory flow rate. Average adult I time is 0.7 to 1 second. I:E ratio is usually 1:2 to 1:4

Positive end-expiratory pressure (PEEP): The amount of positive pressure that is maintained at end-expiration. It is expressed in centimeters of water. The purpose of PEEP is to increase end-expiratory lung volume and reduce air-space closure at end-expiration. Normal Physiologic PEEP is 5cm/H_2O.

Peak flow rate or peak inspiratory flow: The highest flow, or speed, that is set to deliver the V_t during inspiration, usually measured in liters per minute. When the flow rate is set higher, the speed of gas delivery is faster and inspiratory time is shorter.

Peak Airway Pressure (P_{AW}): Represents the total pressure that is required to deliver the V_t and depends upon various airway resistance, lung compliance, and chest wall factors. It is expressed in centimeters of water (cm H_2O).

Sensitivity or trigger sensitivity: Effort, or negative pressure, required by the patient to trigger a machine breath, commonly set so that minimal effort (-1 to -2 cm H_2O) is required to trigger a breath.

Ventilator Transfer Procedure

1. Ensure endotracheal tube is secure, document size and position of ETT at the teeth.

2. Ventilator settings should be coordinated with the transferring physician, anesthesia provider or respiratory therapist. Verify settings, review arterial blood gas (ABG) analysis, and current SPO_2 and $ETCO_2$ readings.

3. ABG should be done within 30 minutes of flight. If time allows, patient should be on transport ventilator for at least 15 minutes prior to transport.

4. The initial tidal volume (V_t) 6 – 10 mL/kg ideal body weight (IBW).

5. Pressure Support: If patient has a spontaneous tidal volume, titrate Pressure Support setting to maintain tidal volume minimum of 4-5 ml/kg, typically 10 cmH_2O.

6. Respiratory rate (RR) should be set to administer a minute ventilation (V_E) of 5 –10 L/min. Maintain $ETCO_2$ between 30-40 mm/Hg. [Current $ETCO_2$ × Current RR ÷ desired $ETCO_2$ = new respiratory rate]

7. PEEP 2-10 cm H_2O

8. I:E Ratio = 1:2 or 1:3

9. FiO_2: Initiate at 100% and titrate FiO_2 to maintain SpO_2 >94%. Wean patient to the lowest level of FiO_2 and PEEP while maintaining SpO_2 >94%. Goal is FiO_2 50-60 and SpO_2 >94%.

Troubleshooting: Airway compromise or lost airway in-flight

Remove patient from circuit and perform bag-valve ventilation with 100% O_2 while troubleshooting (check to ensure patient can fully exhale first in case there was air trapping).

- **DOPE**: Displaced ETT / Obstructed ETT / Pneumothorax / Equipment failure

Ventilator Management

- If at any time patient begins to desaturate or develop respiratory problems, immediately disconnect ventilator and ventilate patient with BVM (with PEEP valve if available) and 100% O_2 while correcting issues utilizing the D.O.P.E. algorithm:
    - Displacement: ETT in place, patient not extubated/ tube did not move during transfer. If advanced – pull back to original length and attempt to bag; if tube has pulled farther out of trachea, DO NOT ATTEMPT TO ADVANCE IT without placement of bougie to verify tracheal placement. When advancing bougie, feel for tracheal rings or carina stop. If in doubt, pull tube and attempt BVM. If this fixes problem, continue to bag patient. Upon stabilization, consider alternative advanced airways (extraglotic airway or cric).

      **If ETT moves freely, access for ETT bulb rupture.
    - Obstructions: Assess for secretions in ETT. Suction if indicated.
    - Pressure: Ensure that a tension pneumothorax / hemothorax has not developed (if chest tube in place, ensure it is functioning/ not kinked or clamped). If tension pneumo/hemothorax suspected, perform immediate needle thoracostomy. Assess the need for escarotomy if circumferential burn. Consider additional paralysis and sedation if patient does not tolerate ventilation.
    - Equipment: Ensure that vent did not fail; O_2 tank not empty. If ventilator is operational, trace all tubes to the patient connection (airway tube, transducer line, exhalation line) ensuring patency and connections.

- **Airway**: Confirm ETT is in appropriate position: look / feel for symmetric chest wall rise and verify tube position Check $ETCO_2$
- Suction ETT if suspected secretion obstruction
- **Breathing**: Look and feel for chest excursion, check SPO_2, check patient's color; Assess for pneumothorax
- **Circulation**: check pulse, BP, and cardiac rhythm
- Assess for equipment failure (e.g., battery, depleted oxygen, vent settings)

Note: Remember, PCO_2 is affected by respiratory rate and tidal volume (ventilation), while PO_2 is affected by PEEP and FiO_2 (oxygenation).

10. **High pressure alarms / Peak airway pressure alarms** (Peak pressure >35 cm H_2O): Correct problems causing increased airway resistance and decreased lung compliance, including pneumothorax or pulmonary edema. Check ventilator to make sure prescribed tidal volume is being delivered.

11. **Air leaks causing low pressure alarms / volume loss**: Assess, correct air leaks in endotracheal tube, tracheostomy cuff, ventilator system; recheck ventilator to make sure prescribed tidal volume is delivered.

12. **Ventilator dyssynchrony**: Agitation and respiratory distress that develop in a patient on a mechanical ventilator who has previously appeared comfortable represents an important clinical circumstance that requires a thorough assessment and an organized approach. The patient should not always be automatically re-sedated, but must instead be evaluated for several potentially life-threatening developments that can present in this fashion.

13. **Lung hyperinflation (air trapping) and auto-PEEP:** Dynamic hyperinflation is associated with positive end-expiratory alveolar pressure, or auto-PEEP. The physiologic effects include decreased cardiac preload because of diminished venous return into the chest. The reduced cardiac output that results from the reduction in preload can lead to hypotension and, if severe, to Pulseless Electrical Activity and cardiac arrest. Dynamic hyperinflation can also lead to local alveolar over-distention and rupture. Prevent, manage lung hyperinflation by decreasing tidal volume, changing inspiratory and expiratory phase parameters, switching to another mode, and correcting physiological abnormalities that increase airway resistance.

III. ADULT PATIENT CARE PROTOCOLS

34. *Determination of Death*

1. GENERAL PROVISIONS:

A. Purpose: The purpose of this policy is to assist SMTs in the determination of death in the field (i.e. pre-hospital setting). This policy is intended to provide SMTs with parameters to be used when determining whether or not to withhold resuscitative efforts and to provide guidelines for the Flight Surgeon for discontinuing resuscitative efforts.

B. Principles:

1) Resuscitative efforts are of no benefit to patients whose physical condition precludes any possibility of successful resuscitation.

2) Shall determine death based on specific criteria set forth in this policy.

3) Cold water drowning, hypothermia and barbiturate ingestion all prolong brain life and therefore treatment and transport should be considered on these patients.

4) The Unit's Flight Surgeon recognizes that SAR Medical Technicians have the discretion to initiate resuscitation in cases where the patient is obviously dead but a concern for unit morale exists. However, the SMT may decide to cease CPR once en route and or out of sight of concerned unit. Note: Given this situation, the SMT may perform CPR so long as:

a) The patient is not decapitated
b) No obvious decomposition (i.e. rigor) is present
c) Doing so does not put the provider and aircrew in danger

2. DEFINITIONS:

A. Obvious Death Criteria: A patient may be determined obviously dead by SAR Medical Technicians if, IN ADDITION to the absence of respiration, cardiac activity, and neurological reflexes, one or more of the following physical or circumstantial conditions exists:

1) Decapitation
2) Massive crush injury to the head, neck, or trunk
3) Penetrating or blunt injury with evisceration of the heart, lung or brain
4) Decomposition
5) Incineration
6) Rigor Mortis
7) Post-Mortem Lividity
8) Absence of vital signs (breathing, clear pulse, organized cardiac activity on a monitor)
9) Pupils fixed and dilated; absence of corneal reflex

B. Traumatic Cardiac Arrest: No pulse, no spontaneous respirations, no response to aggressive stimulation and pupils are fixed.

Determination of Death Cont'd.

A. Assessment: The Patient Assessment shall, at minimum, include the following items which must be documented on the patient's Patient Care Record (PCR):

1) Assure the patient has a patent airway;
2) Look, listen and feel for respirations; and
3) Check for a pulse for a minimum of 60 seconds.
4) Place patient on cardiac monitor (minimum of 3 leads)

B. Procedure:

1) Perform a Primary Assessment:

a. If patient meets obvious death criteria, do not proceed with resuscitation.
b. If a patient has been confirmed pulseless and apneic for at least 10 minutes (CPR having *not* been performed in that 10 minutes), do not proceed with resuscitation.

2) When not to initiate CPR:

a. Primary assessment reveals a pulseless, non-breathing patient who has signs of prolonged lifelessness in accordance with obvious death criteria.
b. A patient with an approved "Do-Not-Resuscitate" (DNR) document in accordance with Department policy.

C. Termination of CPR by SAR Medical Technicians:

1) Providers may discontinue resuscitative efforts as outlined below:

a. Any case in which information becomes available that would have prevented initiation of CPR had that information been available before CPR was initiated, CPR should be terminated.
b. If patient does not meet above criteria, initiate CPR. After 30 minutes of failure to respond to appropriate advanced life support treatment, defined as:

1) Establishment of airway
2) Sustained ventricular fibrillation or ventricular tachycardia with no pulse, despite attempts to defibrillate
3) Adequate medication therapy consistent with the patient's condition and rhythm
4) Successful thoracic needle decompression for trauma victims if indicated

c. If the treatment of one deteriorating patient would apparently lead to the further deterioration or loss of life of the other patient

2) Disposition of the decedent: If a determination of death has occurred and the decedent has not been moved from the original place of death:

a. The decedent shall remain at scene and not be transported:
b. Any treatment items, such as endotracheal tubes, intravenous catheters, ECG or defibrillation electrodes, shall be left in place;
c. Resuscitation equipment, such as bag-valve-mask devices ECG monitoring equipment, etc., may be removed from the deceased.

PAGE INTENTIONALLY

IV. ***ADULT CARDIAC CARE PROTOCOLS***

1. Emergency Cardiac Care 116
2. Asystole & Pulseless Electrical Activity 118
3. Bradycardia 120
4. Tachycardia 122
5. ROSC – Return of Spontaneous Circulation 126
6. Termination or Resuscitation 128

IV. ADULT CARDIAC CARE PROTOCOLS

1. ***Adult Cardiac Arrest***

A. Objectives

1) Early recognition and appropriate intervention of pulseless / apneic adult patients.

B. General Information

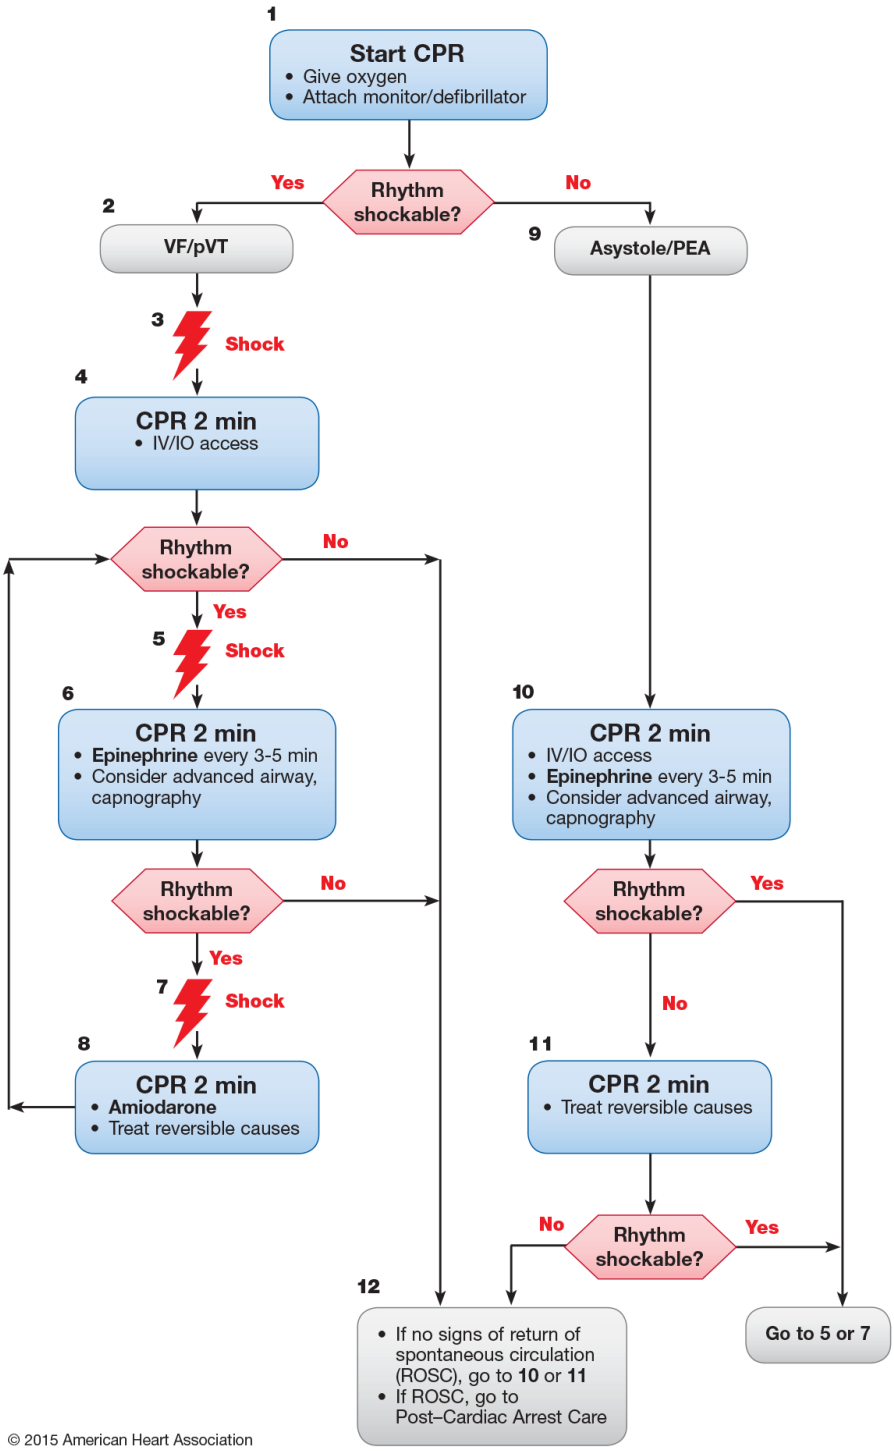
- Cardiopulmonary Resuscitation (CPR)
  a) CPR shall be given IAW 2015 American Heart Association Basic Life Support Guidelines
  b) Push hard and fast (at least 2 inches and at a rate of 100-120/Min)
  c) Ensure full chest recoil
  d) Minimize interruptions in compressions
  e) One cycle of CPR: 30 compressions then 2 breaths; 5 cycles-2min (If no Advanced Airway)
  f) Rotate compressors every 2 min if possible
  g) Check Rhythm every 2 min
  h) After advanced airway is placed, rescuers no longer deliver "cycles" of CPR
     1) Give continuous chest compressions without pauses for breaths
     2) Give 10 breaths/min
- Monitor / Defibrillator Use
  a) Follow appropriate protocol algorithm based on your rhythm analysis.
  b) Contraindications to defibrillation
     1) Rigor / Liver Mortis
     2) No Code / DNR situations
  c) If Patient successfully regains a pulse, maintain airway and ventilations as necessary and continue to monitor a pulse.

*If Patient becomes pulseless during transport, start CPR, and analyze rhythm.

C. Warnings / Alerts

- CPR may still be required in the presence of an organized cardiac rhythm.
- It is the responsibility of the provider delivering the shock to ensure that no one is touching the patient prior to shock delivery.
- Ensure that the patient is dried off and not laying in water prior to defibrillation.
- Ensure that transdermal medications are taken off and wiped clean prior to defibrillation.

Adult Cardiac Arrest Algorithm—2015 Update



© 2015 American Heart Association

CPR Quality

- Push hard (at least 2 inches [5 cm]) and fast (100-120/min) and allow complete chest recoil.
- Minimize interruptions in compressions.
- Avoid excessive ventilation.
- Rotate compressor every 2 minutes, or sooner if fatigued.
- If no advanced airway, 30:2 compression-ventilation ratio.
- Quantitative waveform capnography
  - If P_{ETCO_2} <10 mm Hg, attempt to improve CPR quality.
- Intra-arterial pressure
  - If relaxation phase (diastolic) pressure <20 mm Hg, attempt to improve CPR quality.

Shock Energy for Defibrillation

- **Biphasic:** Manufacturer recommendation (eg, initial dose of 120-200 J); if unknown, use maximum available. Second and subsequent doses should be equivalent, and higher doses may be considered.
- **Monophasic:** 360 J

Drug Therapy

- **Epinephrine IV/IO dose:** 1 mg every 3-5 minutes
- **Amiodarone IV/IO dose:** First dose: 300 mg bolus. Second dose: 150 mg.

Advanced Airway

- Endotracheal intubation or supraglottic advanced airway
- Waveform capnography or capnometry to confirm and monitor ET tube placement
- Once advanced airway in place, give 1 breath every 6 seconds (10 breaths/min) with continuous chest compressions

Return of Spontaneous Circulation (ROSC)

- Pulse and blood pressure
- Abrupt sustained increase in P_{ETCO_2} (typically ≥40 mm Hg)
- Spontaneous arterial pressure waves with intra-arterial monitoring

Reversible Causes

- **H**ypovolemia
- **H**ypoxia
- **H**ydrogen ion (acidosis)
- **H**ypo-/hyperkalemia
- **H**ypothermia
- **T**ension pneumothorax
- **T**amponade, cardiac
- **T**oxins
- **T**hrombosis, pulmonary
- **T**hrombosis, coronary

2. ***Adult Asystole and Pulseless Electrical Activity***

A) Objectives:

1) Early recognition and appropriate intervention of pulseless / apneic adult patients.
2) Early appropriated recognition of lethal rhythms.

B) General Information:

- CPR shall be given IAW 2015 American Heart Association Basic Life Support Guidelines.
- Endotracheal administration of medications should be used ONLY when IV/IO access is not available.
- Search for and treat possible contributing factors using appropriate protocol for:
  - a) Hypovolemia
  - b) Hypoxia
  - c) Hypokalemia / Hyperkalemia
  - d) Hypoglycemia
  - e) Hypothermia / Hyperthermia
  - f) Hydrogen ion- (Acidosis)
  - g) Tension Pneumothorax
  - h) Toxins
  - i) Trauma
  - j) Tamponade Cardiac
  - k) Thrombosis (coronary or pulmonary)
- For cardiac arrest in renal patients administer Calcium Chloride 1 gm IV/IO push followed by 40 ml flush, Sodium Bicarbonate 1 Meq/kg and repeat in 10.

C) Warnings / Alerts

- CPR may still be required in the presence of an organized cardiac rhythm.

- **T**hrombosis, coronary

3. ***Adult Bradycardia***

A) Objectives:

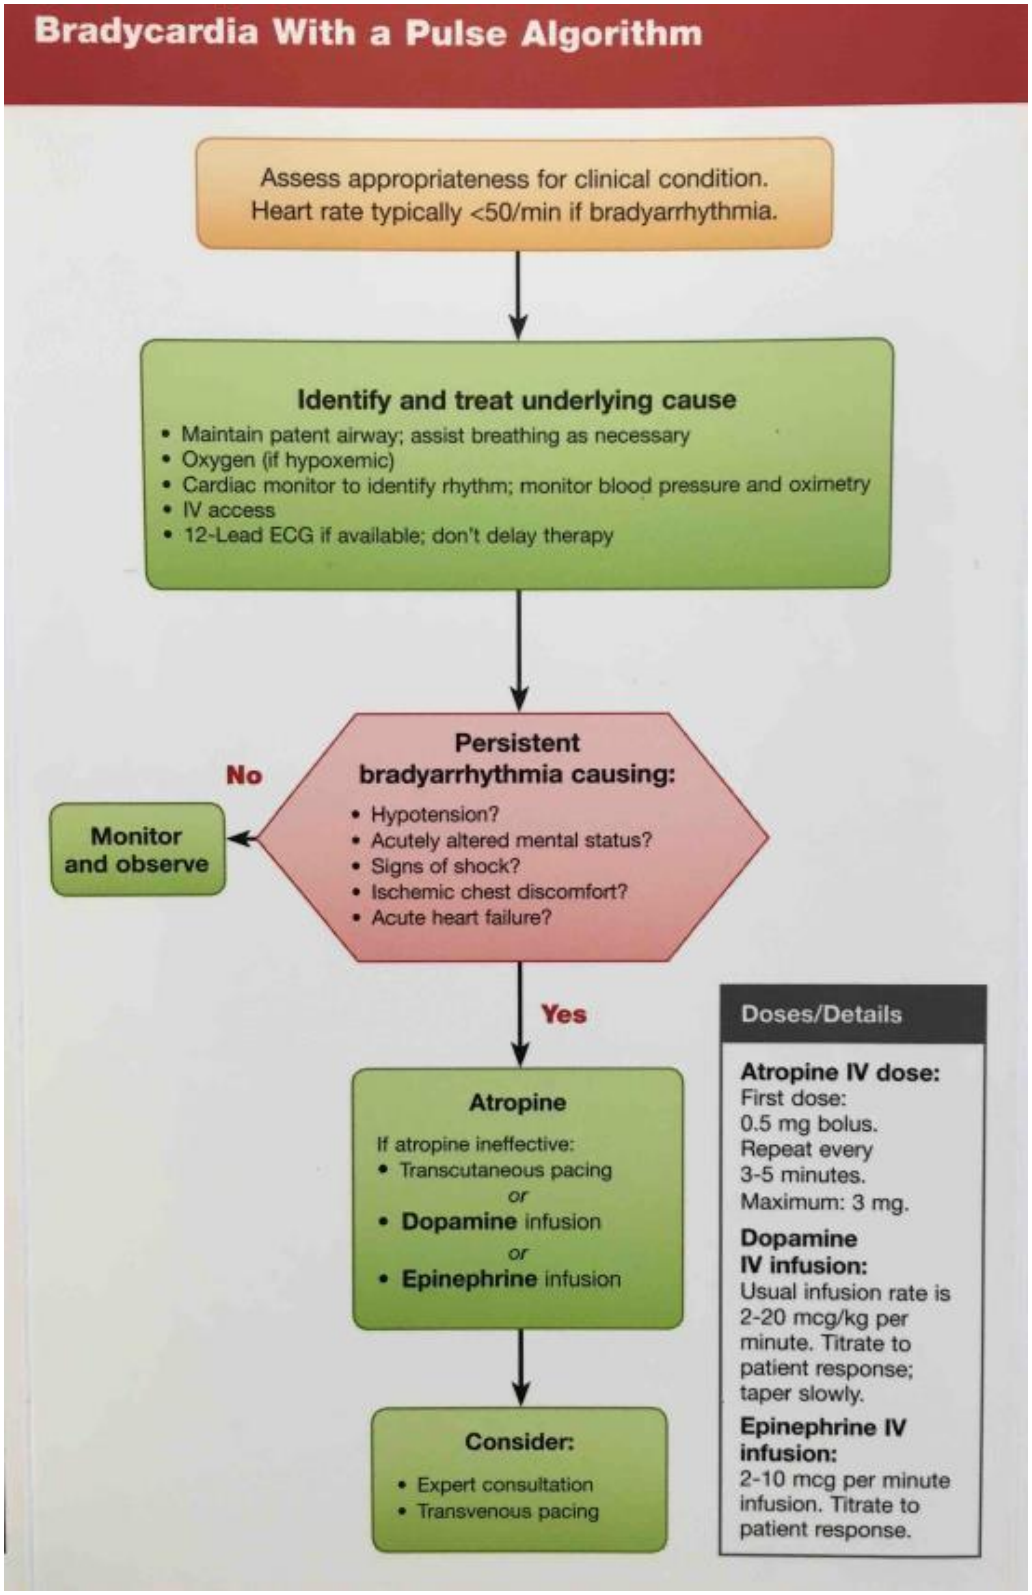
1) Early appropriate recognition and management of bradycardic rhythms.
2) Recognition of poor perfusion attributed to a bradycardic rhythm.

B) General Information:

- Signs and symptoms of poor perfusion include:
  a) New onset of altered mental status
  b) Ongoing chest pain
  c) Hypotension Systolic B/P less than 90. with associated signs and symptoms.
- If patient is stable, Atropine is first line medication.
- External Pacing
  a) Consider pain control and/or sedation
  b) Do not delay pacing for administration of medication
- Dopamine Drip
  a) Premixed Drip is preferred
  i) If not available then add 400 mg of Dopamine to 250 ml NS for concentration of 1600 mcg/ml
  b) Dose 2-10 mcg/kg/min
- Epinephrine Drip
  a) Add 0.4 mg of Epinephrine 1:1000 to 100 ml NS for a concentration of 4mcg/ml
  i) Dose 2-10 mcg/min
  b) Epinephrine Push Dose 1/100,000
  (i) Draw 1 ml of Epi 1/10,000 into 9 mL NS 10 mcg/mL
  Loading dose: 20 mcg/2mL
  Continuous Dosing: 10mcg/1mL/min
  To maintain SBP of >100 mmHg

C) Warnings/Alerts

- Patient may deteriorate due to unnecessary delay in pacing.
- Failure to recognize electrical and mechanical capture may lead to patient deterioration.
- Assessment of a carotid pulse may be inaccurate due to muscle jerking which may mimic a carotid pulse.
- Patients that are hypothermic should not be paced.
- Consider analgesia or sedation for pacing.



Bradycardia With a Pulse Algorithm
Assess appropriateness for clinical condition.
Heart rate typically <50/min if bradyarrhythmia.
Identify and treat underlying cause
• Maintain patent airway; assist breathing as necessary
• Oxygen (if hypoxemic)
• Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
• IV access
• 12-Lead ECG if available; don't delay therapy
Persistent bradyarrhythmia causing:
• Hypotension?
• Acutely altered mental status?
• Signs of shock?
• Ischemic chest discomfort?
• Acute heart failure?
No
Monitor and observe
Yes
Atropine
If atropine ineffective:
• Transcutaneous pacing
or
• Dopamine infusion
or
• Epinephrine infusion
Consider:
• Expert consultation
• Transvenous pacing
Doses/Details
Atropine IV dose:
First dose:
0.5 mg bolus.
Repeat every
3-5 minutes.
Maximum: 3 mg.
Dopamine IV infusion:
Usual infusion rate is 2-20 mcg/kg per minute. Titrate to patient response; taper slowly.
Epinephrine IV infusion:
2-10 mcg per minute infusion. Titrate to patient response.

IV. ADULT CARDIAC CARE PROTOCOLS

4 Cont. ***Adult Tachycardia- Narrow***

A) Objectives:

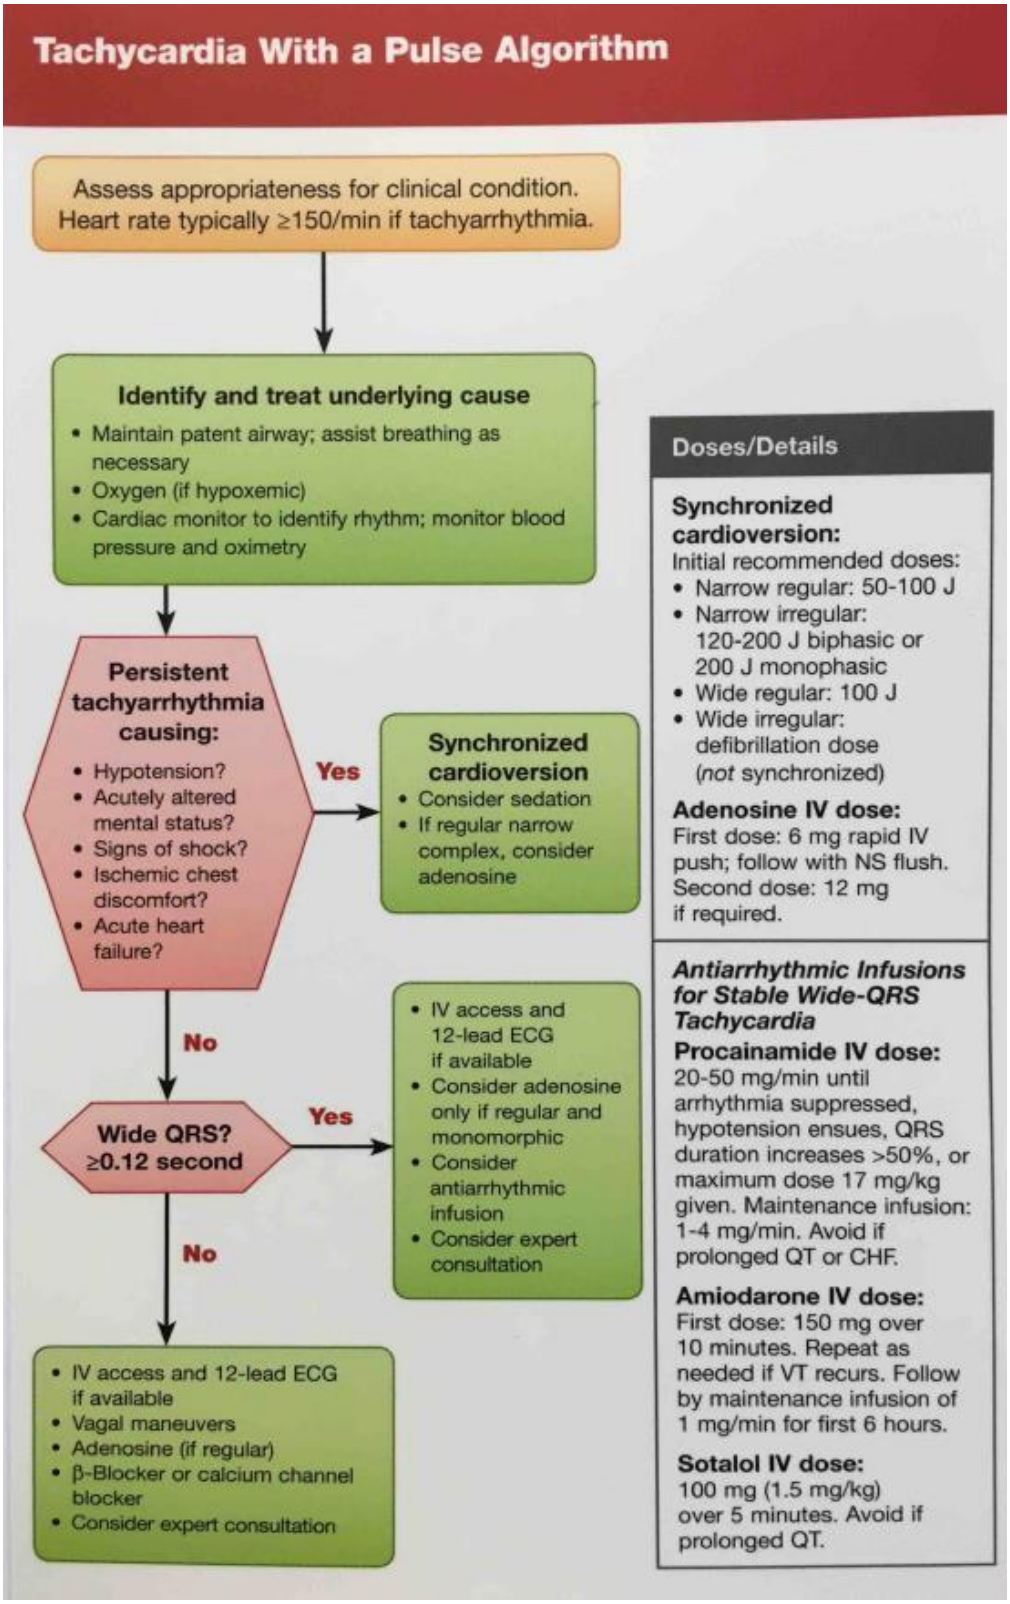
1) Early appropriate recognition and management of narrow complex tachycardia rhythms.
2) Recognition of poor perfusion attributed to a narrow complex tachycardia rhythm.

B) General Information:

- Signs and symptoms of a hemodynamically unstable patient include:
  a) Altered mental status
  b) Ongoing chest discomfort
  c) Shortness of breath
  d) Hypotension
  e) Shock
- Heart rate of 150/minute is one factor to distinguish SVT from sinus tach. Younger adult patients may experience sinus tach at rates greater than 150/minute and older patients may have SVT at rates lower than 150/minute. Other considerations should include presence/absence of P waves, beat to beat variability and patient history; if unsure of treatment contact medical control.
- If the patient has cocaine-induced SVT, administer Valium 5 mg IV/IO.

C) Warnings/Alerts

- Avoid low energy unsynchronized defibrillations. Low energy unsynchronized defibrillations are likely to induce ventricular fibrillation.
- If unable to obtain synchronization, deliver unsynchronized shock at defibrillation energy (manufacturer recommendations) not to delay cardioversion for administration of sedation to the unstable patient.
- It is the responsibility of the provider delivering the shock to ensure that no one is touching the patient prior to shock delivery.
- The following conditions need to be addressed prior to cardioversion:
  a) Patients in standing water
  b) Patients with transdermal medications
- Adenosine is contra-indicated in patients with a history of WPW.



Tachycardia With a Pulse Algorithm
Assess appropriateness for clinical condition. Heart rate typically ≥150/min if tachyarrhythmia.
Identify and treat underlying cause
• Maintain patent airway; assist breathing as necessary
• Oxygen (if hypoxemic)
• Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
Persistent tachyarrhythmia causing:
• Hypotension?
• Acutely altered mental status?
• Signs of shock?
• Ischemic chest discomfort?
• Acute heart failure?
Yes
Synchronized cardioversion
• Consider sedation
• If regular narrow complex, consider adenosine
No
Wide QRS? ≥0.12 second
Yes
• IV access and 12-lead ECG if available
• Consider adenosine only if regular and monomorphic
• Consider antiarrhythmic infusion
• Consider expert consultation
No
• IV access and 12-lead ECG if available
• Vagal maneuvers
• Adenosine (if regular)
• β-Blocker or calcium channel blocker
• Consider expert consultation
Doses/Details
Synchronized cardioversion:
Initial recommended doses:
• Narrow regular: 50-100 J
• Narrow irregular: 120-200 J biphasic or 200 J monophasic
• Wide regular: 100 J
• Wide irregular: defibrillation dose (not synchronized)
Adenosine IV dose:
First dose: 6 mg rapid IV push; follow with NS flush. Second dose: 12 mg if required.
Antiarrhythmic Infusions for Stable Wide-QRS Tachycardia
Procainamide IV dose:
20-50 mg/min until arrhythmia suppressed, hypotension ensues, QRS duration increases >50%, or maximum dose 17 mg/kg given. Maintenance infusion: 1-4 mg/min. Avoid if prolonged QT or CHF.
Amiodarone IV dose:
First dose: 150 mg over 10 minutes. Repeat as needed if VT recurs. Follow by maintenance infusion of 1 mg/min for first 6 hours.
Sotalol IV dose:
100 mg (1.5 mg/kg) over 5 minutes. Avoid if prolonged QT.

IV. ADULT CARDIAC CARE PROTOCOLS

4 Cont. ***Adult Tachycardia - Wide***

A) Objectives

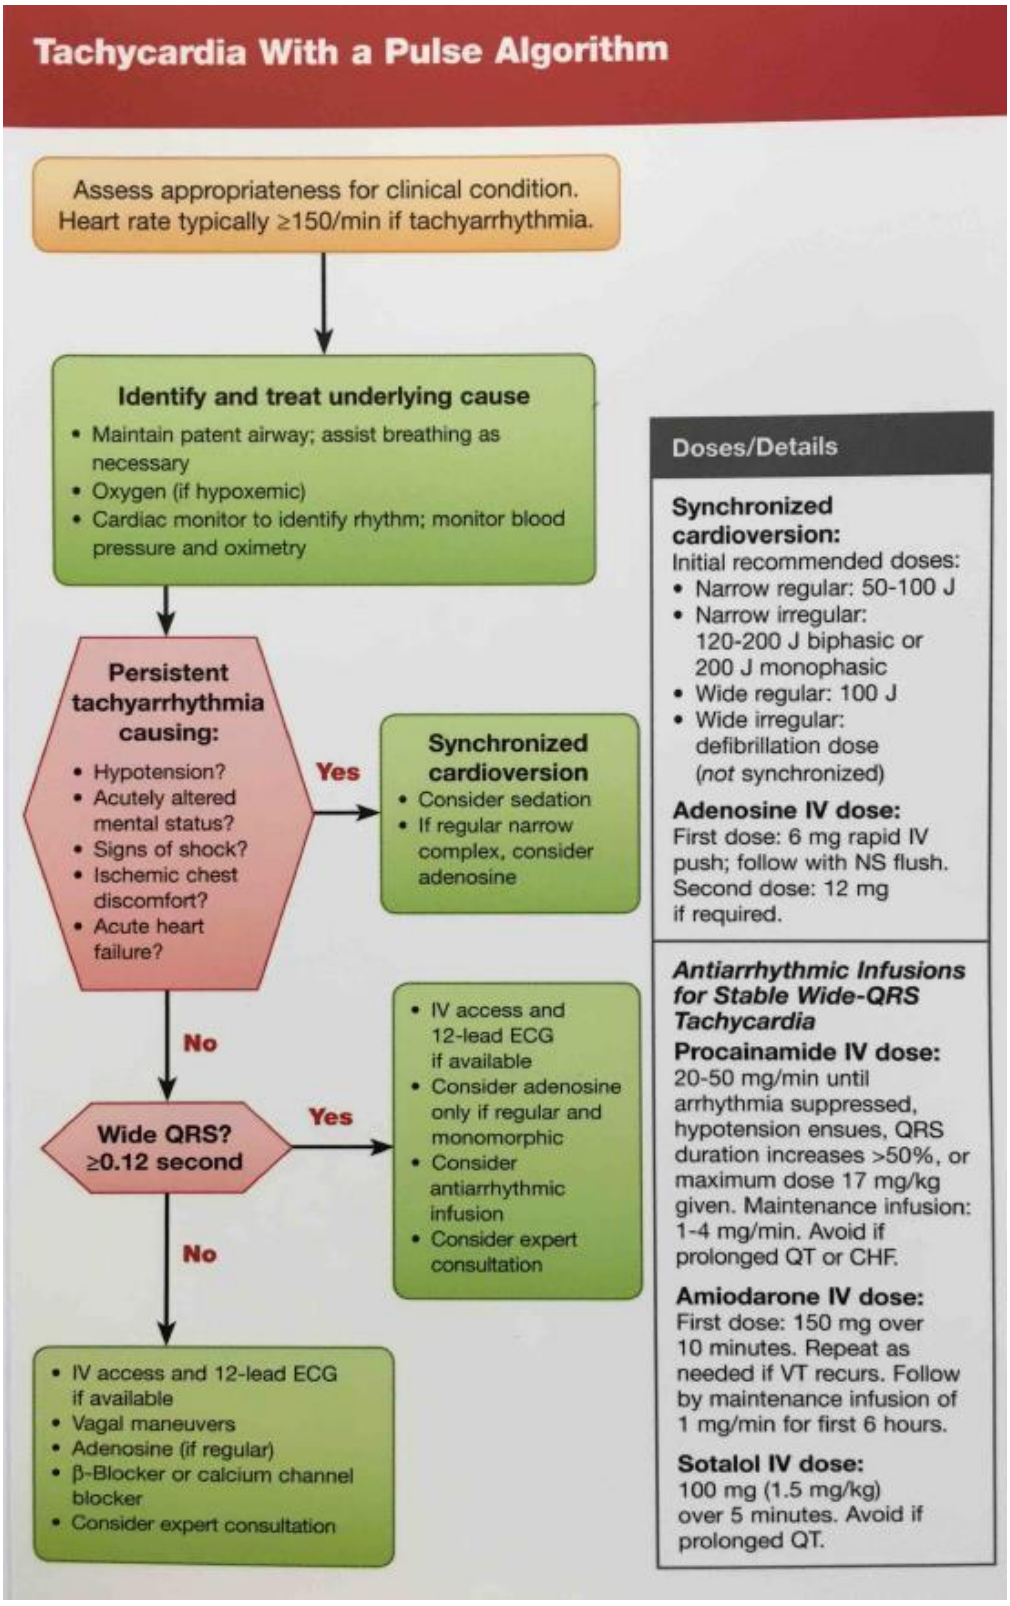
1) Early appropriate recognition and management of tachycardia rhythms.
2) Recognition of poor perfusion attributed to a tachycardia rhythm Adult Tachycardia – Wide Complex.

B) General Information

- Signs and Symptoms of a hemodynamically unstable patient include:
  a) Altered mental status
  b) Ongoing chest discomfort
  c) Shortness of breath
  d) Hypotension
  e) Shock
- Although not common, V-Tach can occur at rates less than 150; if unsure of treatment contact medical control

C) Warnings/Alerts

- Polymorphic VT can deteriorate quickly to VF – defibrillate ASAP.
- Avoid low energy unsynchronized defibrillations. Low energy unsynchronized defibrillations are likely to induce ventricular fibrillation.
- If unable to obtain synchronization, deliver unsynchronized shock at defibrillation energy (manufacturer recommendations).
- Do not delay cardioversion for administration of sedation to the unstable patient.
- It is the responsibility of the provider delivering the shock to ensure that no one. Is touching the patient prior to shock delivery
- The following conditions need to be addressed prior to cardioversion
  a) Patients in standing water
  b) Patients with transdermal medications
- Other conditions may mimic wide complex tachycardia
  a) Internal pacemakers
  b) Aberrancy



Tachycardia With a Pulse Algorithm
Assess appropriateness for clinical condition. Heart rate typically ≥150/min if tachyarrhythmia.
Identify and treat underlying cause
• Maintain patent airway; assist breathing as necessary
• Oxygen (if hypoxemic)
• Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
Persistent tachyarrhythmia causing:

• Consider adenosine only if regular and monomorphic
• Consider antiarrhythmic infusion
• Consider expert consultation
No
• IV access and 12-lead ECG if available
• Vagal maneuvers
• Adenosine (if regular)
• β-Blocker or calcium channel blocker
• Consider expert consultation
Doses/Details
Synchronized cardioversion:
Initial recommended doses:
• Narrow regular: 50-100 J
• Narrow irregular: 120-200 J biphasic or 200 J monophasic
• Wide regular: 100 J
• Wide irregular: defibrillation dose (not synchronized)
Adenosine IV dose:
First dose: 6 mg rapid IV push; follow with NS flush. Second dose: 12 mg if required.
Antiarrhythmic Infusions for Stable Wide-QRS Tachycardia
Procainamide IV dose:
20-50 mg/min until arrhythmia suppressed, hypotension ensues, QRS duration increases >50%, or maximum dose 17 mg/kg given. Maintenance infusion: 1-4 mg/min. Avoid if prolonged QT or CHF.
Amiodarone IV dose:
First dose: 150 mg over 10 minutes. Repeat as needed if VT recurs. Follow by maintenance infusion of 1 mg/min for first 6 hours.
Sotalol IV dose:
100 mg (1.5 mg/kg) over 5 minutes. Avoid if prolonged QT.

IV. ADULT CARDIAC CARE PROTOCOLS

5. ***Return of Spontaneous Circulation (ROSC)***

A) Objectives

1) To appropriately treat patients who have return of spontaneous circulation.
2) To ensure adequate perfusion.

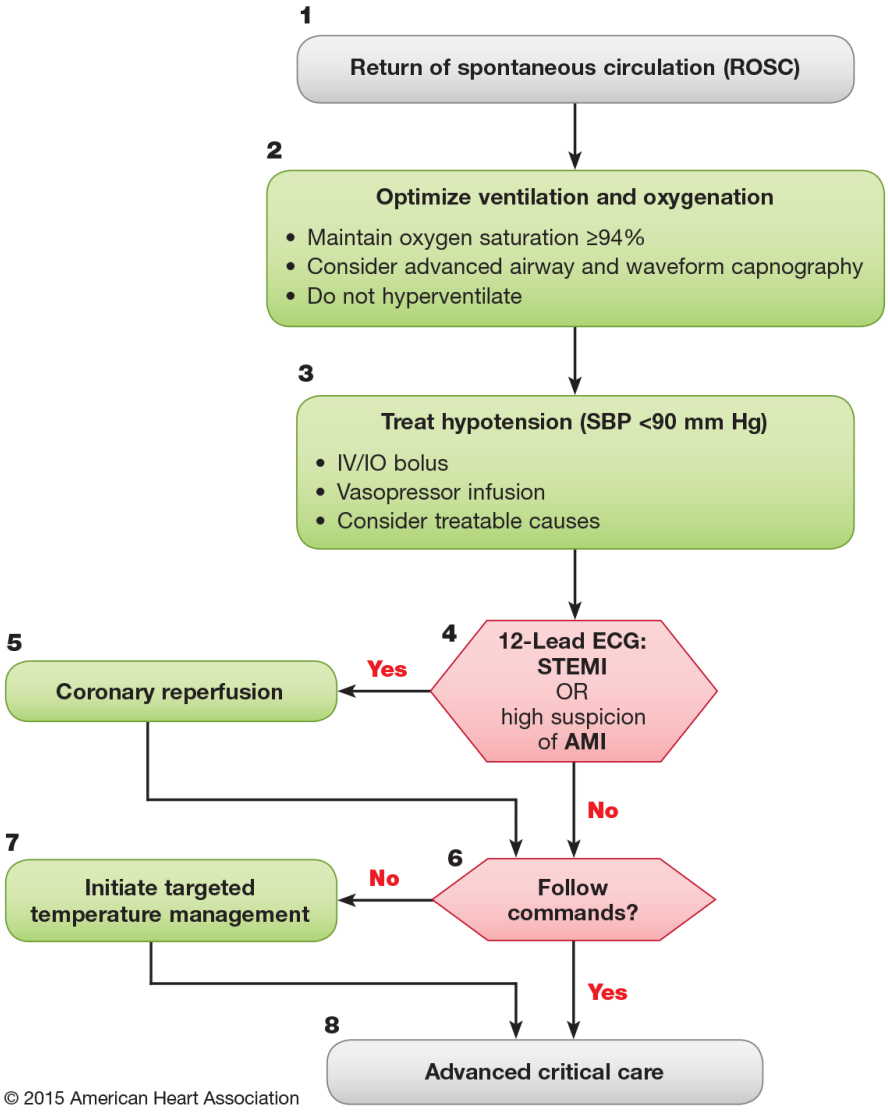
B) General Information

- Amiodarone:
  a) 150 mg in 100 ml over 10 minutes
  b) Do not use in the same IV line with furosemide, heparin or sodium bicarbonate
- Dopamine:
  a) Starting dose 2 mcg/kg/min
  b) Max dose of 20 mcg/kg/min
  c) Titrate to systolic blood pressure of 90-100 mm/Hg
  d) Mix 400 mg in 250 ml NS for a concentration of 1600 mcg/ml; see reference chart for drip rate

C) Warnings/ Alerts

- Amiodarone is contraindicated in the following conditions:
  a) Bradycardia
  b) Heart block
  c) Hypotension
  d) Pulmonary edema
  e) Cardiogenic shock

Adult Immediate Post–Cardiac Arrest Care Algorithm—2015 Update



Doses/Details

Ventilation/oxygenation: Avoid excessive ventilation. Start at 10 breaths/min and titrate to target P_{ETCO_2} of 35-40 mm Hg. When feasible, titrate F_{IO_2} to minimum necessary to achieve Spo_2 ≥94%.

IV bolus: Approximately 1-2 L normal saline or lactated Ringer's

Epinephrine IV infusion: 0.1-0.5 mcg/kg per minute (in 70-kg adult: 7-35 mcg per minute)

Dopamine IV infusion: 5-10 mcg/kg per minute

Norepinephrine IV infusion: 0.1-0.5 mcg/kg per minute (in 70-kg adult: 7-35 mcg per minute)

Reversible Causes

- **H**ypovolemia
- **H**ypoxia
- **H**ydrogen ion (acidosis)
- **H**ypo-/hyperkalemia
- **H**ypothermia
- **T**ension pneumothorax
- **T**amponade, cardiac
- **T**oxins
- **T**hrombosis, pulmonary
- **T**hrombosis, coronary

6. ***Termination of resuscitation***

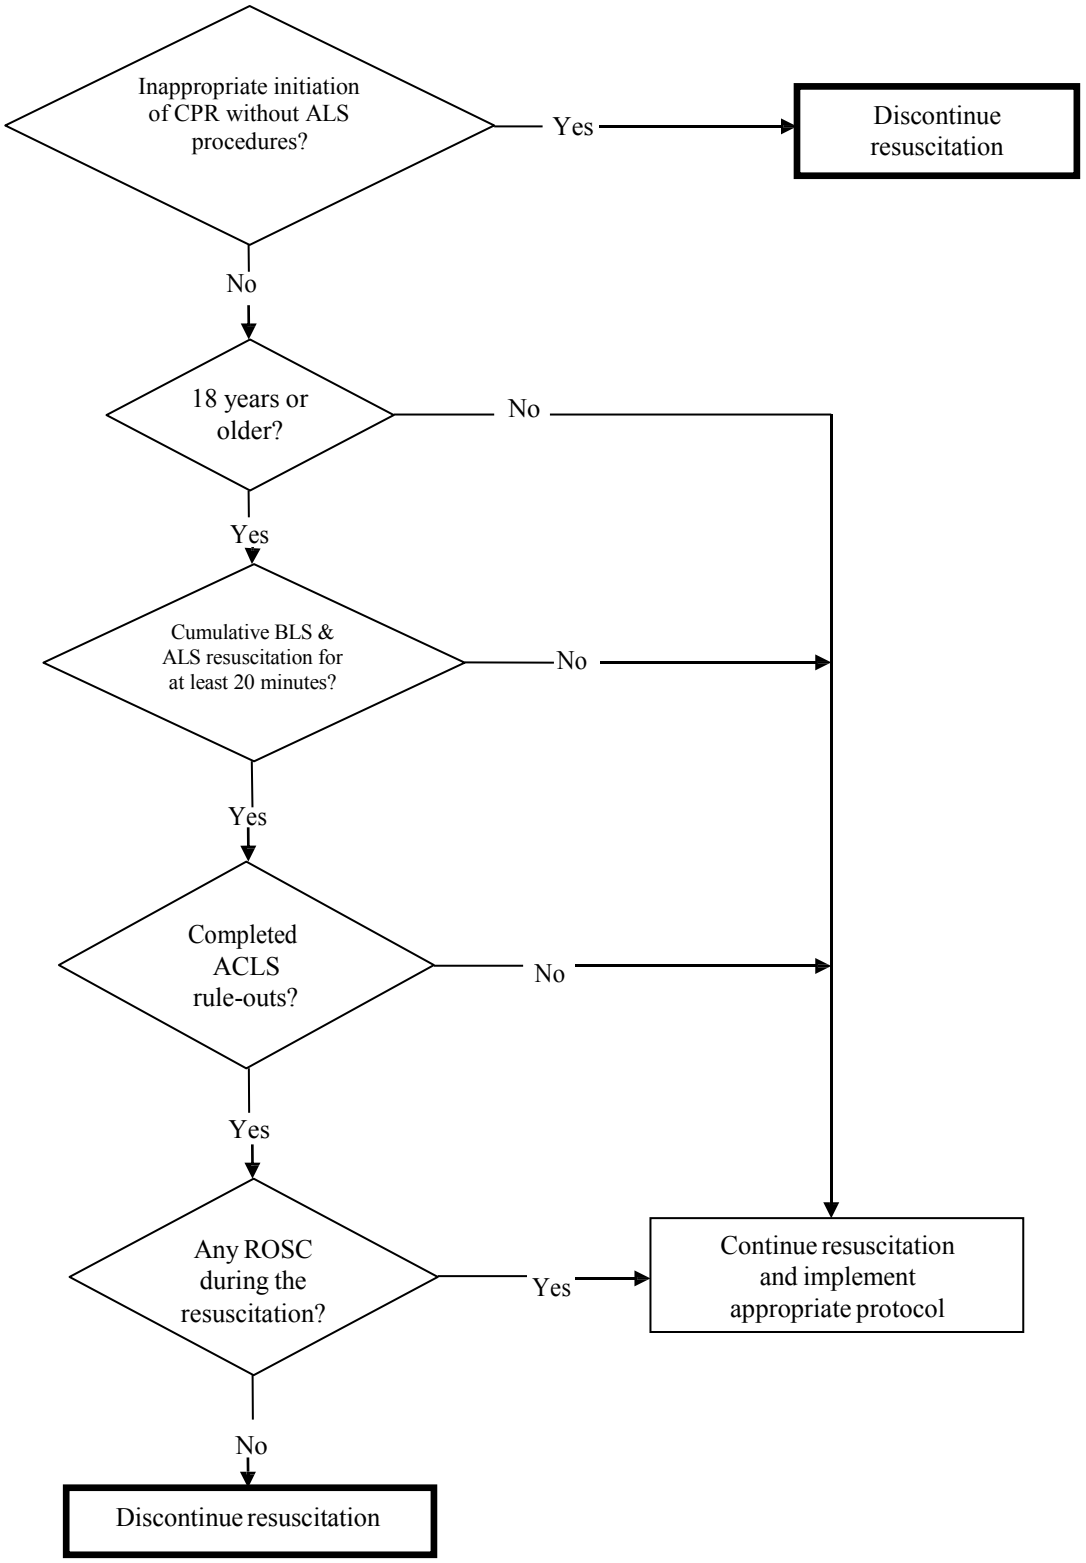
A) Objectives
   1) To provide criteria for field terminating resuscitation.

B) General Information
- Contraindications to using the protocol include patients who are exhibiting neurological activity, patients under 18 years old, or patients with suspected hypothermia.
- Inappropriate initiation of CPR includes patients with dependent lividity, rigor mortis, injuries incompatible with life or a valid DNR.
- Resuscitation must continue while you are evaluating the patient.
- Patients in cardiac arrest from environmental causes may warrant resuscitation efforts greater than 20 minutes (ie hypothermia, submersion injuries etc.).
- Once resuscitation has been discontinued
  a) Distribute bereavement booklet to family members, if available
  b) Leave all expendable ALS supplies in place

C) Warnings / Alerts

- This protocol is not to be used during transport (transport is defined as moving the patient into the aircraft)
- Recent studies have shown that resuscitation outcomes for witnessed arrest have had ROSC at times greater than 20 minutes while maintaining a refractory Ventricular Fibrillation rhythm in these patients. Sound judgment and all aspects of the patient situation should be held into consideration prior to any termination of efforts in these patients.

Termination of resuscitation



PAGE INTENTIONALLY

LEFT BLANK

V. PEDIATRIC GUIDELINES

1. General Information 132
2. Clinical Reference charts for Pediatric(s) / Neonate(s) 133
3. JUMP START Triage 134
4. APGAR / Glasgow Coma Scale 136
5. Neonate / Pediatric Burn Reference 137
6. Pediatric Cardiac Arrest 138
7. Pediatric Bradycardia 139
8. Pediatric Tachycardia 140

V. PEDIATRIC GUIDELINES

1. General information:

Pediatric and Neonatal patients are not typically in the SAR Medical Technicians Scope of Practice, but have the potential to become patients under our care. The following charts are tools to help the SAR Medical Technician in treatment of Pediatric and Neonatal patients.

References to ALS EMS Field Guide (AHA2015), AHA ACLS/PALS Handbook, or BRASLOW Child Reference Tape shall be done anytime treatment is being conducted on a Pediatric or Neonatal patient. Next level of care shall be notified while transporting Pediatric and Neonatal patients.

2. Important reminders for providers treating Pediatric and Neonatal patients:

- Up until the age of 8, a child's head is proportionally large and contains 25% of total body weight.
- A Child's Airway is narrower and less stable at all levels than those of adults.
- Small amounts of blood loss in children can cause shock.
- Children can compensate in shock for long periods of time, during this time it is vital to perform lifesaving and shock treatment. When children start to decompensate in shock it tends to be irreversible. Aggressive stabilization of Pediatric and Neonate patients is key to managing these patients.

3. Clinical Reference charts for Pediatric(s) / Neonate(s):

Age	Preterm	Term	6 Months	1YR	3YR	6YR	8YR	10YR	11YR	12YR	14YR

V. PEDIATRIC GUIDELINES

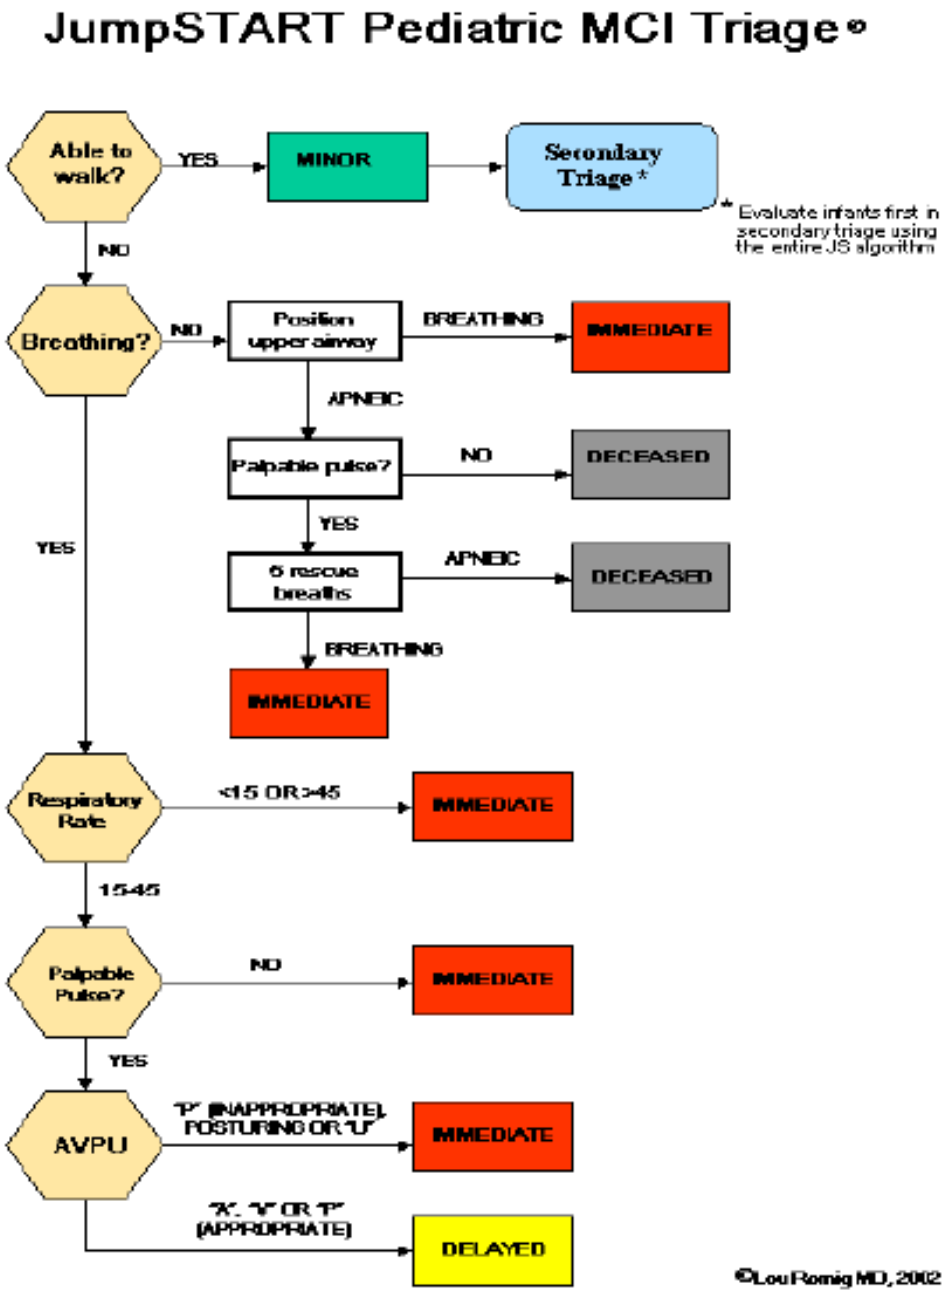
3. Jump START Triage



JumpStart Triage

Indications: Trauma patients who meet any of the following criteria shall be transported to the **closest appropriate** trauma center within a 30-minute ground transport time. Trauma patients who are not within 30 minutes ground transport time of a trauma center should be transported to the closest hospital if they cannot be delivered to an appropriate facility more rapidly by air ambulance.

Physiologic Criteria

- Glascow Coma Scale less than 14, or
- Systolic blood pressure of less than 90 mm/Hg, or
- Respiratory rate of less than 10 or greater than 29 breaths per minute (less than 20 breaths per minute in infants less than 1 year old)

Anatomic Criteria

- Penetrating injuries to head, neck, torso and extremities proximal to elbow or knee
- Flail Chest
- 2 or more proximal long bone fracures
- Crushed, degloved or mangled extremity
- Amputation proximal to wrist or ankle
- Pelvic fractures
- Open or depressed skull fractures
- Paralysis

Mechanism of Injury

- **Falls**
  - Adults – greater than 20 feet
  - Children less than 15 years old – greater than 10 feet, or 2-3 times the child's height
- **High-risk auto crash**
  - Intrusion- more than 12 inches to the occupant site or more than 18 inches to any site
  - Ejection (partial or complete) from automobile
  - Death in the same passenger compartment
  - Vehicle telemetry data consistent with high risk of injury
- **Auto versus pedestrian / bicyclists**- thrown, run over or with significant (greater than 20 mph) impact
- **Motorcycle crash** at speed greater than 20 mph
- **Special Considerations**
- **Burns** (with or without other trauma) – absent other trauma, burns that meet Burn Center criteria should be transported to a burn center
- **Pregnancy**- Injured women who are more than 20 weeks pregnant should be considered for transport to a trauma center or a hospital with obstetrical resources
- **Age** – greater than 55 years of age
- **Anticoagulation and Bleeding Disorders** – EMS should contact medical control and consider transport to trauma center
- **Time- Sensitive Extremity Injury** – open fracture(s) or fracture(s) with neurovascular compromise
- **EMS Provider Judgment** – EMS provides, based on experience and expertise, may always exercise clinical judgment regarding atypical patient presentations

V. PEDIATRIC GUIDELINES

4. APGAR / Glasgow Coma Scale

APGAR / Glasgow Coma Scale Score / Pain Rating Scale

APGAR

Sign	0	1	2
Appearance (skin color)	Blue, pale	Body pink, blue extremities	Completely pink
Pulse rate (heart rate)	Absent	<100 beats/minute	>100 beats/minute
Grimace (irritability)	No response	Grimace	Cough, sneeze, cry
Activity (muscle tone)	Limp	Some flexion	Active motion
Respirations (effort)	Absent	Slow, irregular	Good, crying

Pediatric Glasgow Coma Scale (GCS) Score

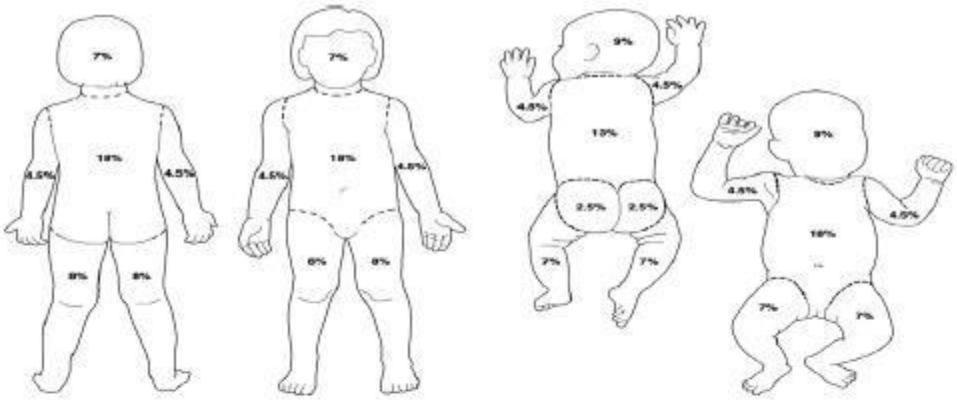
Eye	Verbal	Motor
4 – Spontaneous eye opening 3 – Eye opening on command 2 – Eye opening to painful stimulus 1 – No eye opening *If eye(s) cannot be opened due to severe swelling, the patient should receive the score based on what he/she would be able to do	*>5 Years of Age* 5 – Oriented and converses 4 – Disoriented and converses 3 – Inappropriate words 2 – Incomprehensible sounds 1 – Makes no verbal response *2-5 Years of Age* 5 – Appropriate words and phrases 4 – Inappropriate words 3 – Cries/screams 2 – Grunts 1 – Makes no verbal response *Birth to 2 Years of Age* 5 – Cries appropriately, smiles, coos 4 – Cries 3 – Inappropriate crying/screaming 2 – Grunts 1 – Makes no verbal response *See note about intubation	6 – Follows command 5 – Localizes painful stimuli 4 – Withdrawal to pain 3 – Responds with abnormal flexion to painful stimuli (decorticate) 2 – Responds with abnormal extension to painful stimuli (decerebrate) 1 – Gives no motor response
• If patient intubated, GCS score contains only eye and motor scales and a "T" is added to note the inability to assess verbal response (e.g., "8T")		

Pediatric Pain Rating Scale

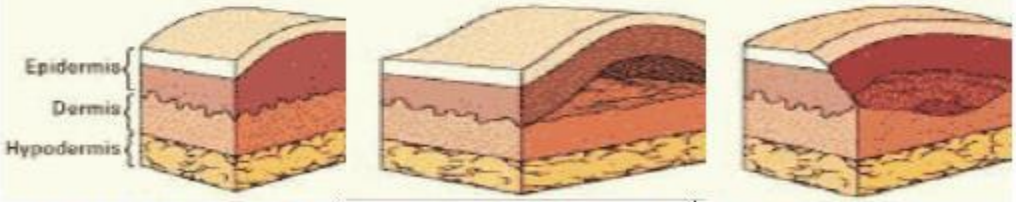
Explain to the child that each face is for a person who feels happy because there is no pain (hurt) or sad because there is some or a lot of pain. Face 0 is very happy because there is no hurt. Face 2 hurts just a little bit. Face 4 hurts a little more. Face 6 hurts even more. Face 8 hurts a whole lot, but Face 10 hurts as much as you can imagine, although you do not have to be crying to feel this bad. Ask child to choose the face that best describes the child's own pain. Record the number under chosen face on patient care report.

V. PEDIATRIC GUIDELINES

5. Neonate / Pediatric Burn Reference



Palm Method:
The palm method is a tool whereby the size of the patients palm is used as an indicator for specific percentage of TBSA.
The surface area of a patients palm equals approximately 1% of TBSA.
This method is particularly useful where the burn has an irregular shape or has a scattered distribution.

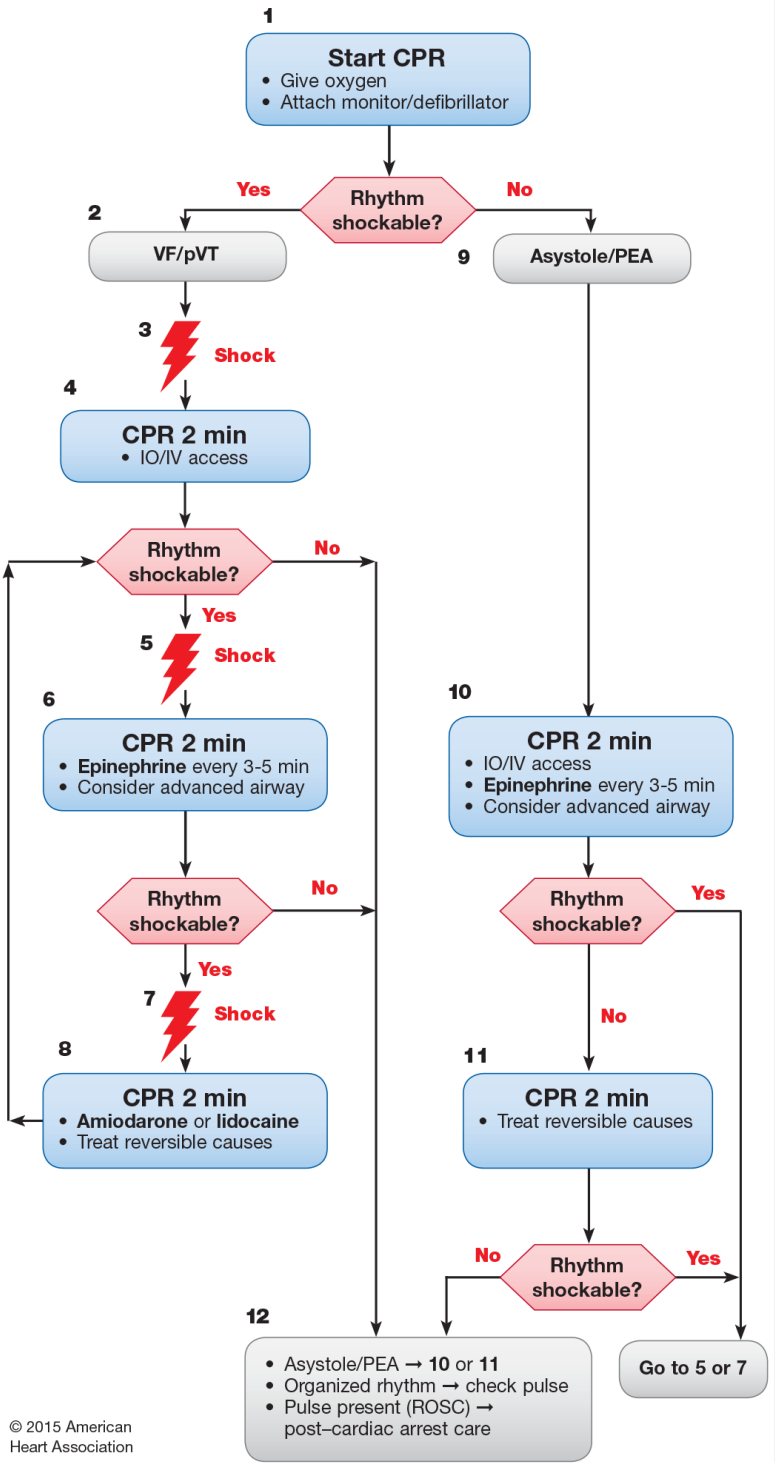
Superficial (First-Degree)	Partial Thickness (Second-Degree)	Full Thickness (Third-Degree)
		


Damage to the outer layer of skin {epidermis}, causing pain, redness and swelling.	Damage to both outer skin and underlying tissue layers {epidermis and dermis} causing pain, redness, swelling and blistering.	Damage extends deeper into tissues {epidermis, dermis and hypodermis} causing extensive tissue destruction. The skin may feel numb.

V. PEDIATRIC GUIDELINES

6. Pediatric Cardiac Arrest

Pediatric Cardiac Arrest Algorithm—2015 Update



© 2015 American Heart Association

CPR Quality

- Push hard (≥⅓ of anteroposterior diameter of chest) and fast (100-120/min) and allow complete chest recoil.
- Minimize interruptions in compressions.
- Avoid excessive ventilation.
- Rotate compressor every 2 minutes, or sooner if fatigued.
- If no advanced airway, 15:2 compression-ventilation ratio.

Shock Energy for Defibrillation

First shock 2 J/kg, second shock 4 J/kg, subsequent shocks ≥4 J/kg, maximum 10 J/kg or adult dose

Drug Therapy

- **Epinephrine IO/IV dose:** 0.01 mg/kg (0.1 mL/kg of 1:10 000 concentration). Repeat every 3-5 minutes.
  If no IO/IV access, may give endotracheal dose: 0.1 mg/kg (0.1 mL/kg of 1:1000 concentration).
- **Amiodarone IO/IV dose:** 5 mg/kg bolus during cardiac arrest. May repeat up to 2 times for refractory VF/pulseless VT.
- **Lidocaine IO/IV dose:** Initial: 1 mg/kg loading dose. Maintenance: 20-50 mcg/kg per minute infusion (repeat bolus dose if infusion initiated >15 minutes after initial bolus therapy).

Advanced Airway

- Endotracheal intubation or supraglottic advanced airway
- Waveform capnography or capnometry to confirm and monitor ET tube placement
- Once advanced airway in place, give 1 breath every 6 seconds (10 breaths/min) with continuous chest compressions

Return of Spontaneous Circulation (ROSC)

- Pulse and blood pressure
- Spontaneous arterial pressure waves with intra-arterial monitoring

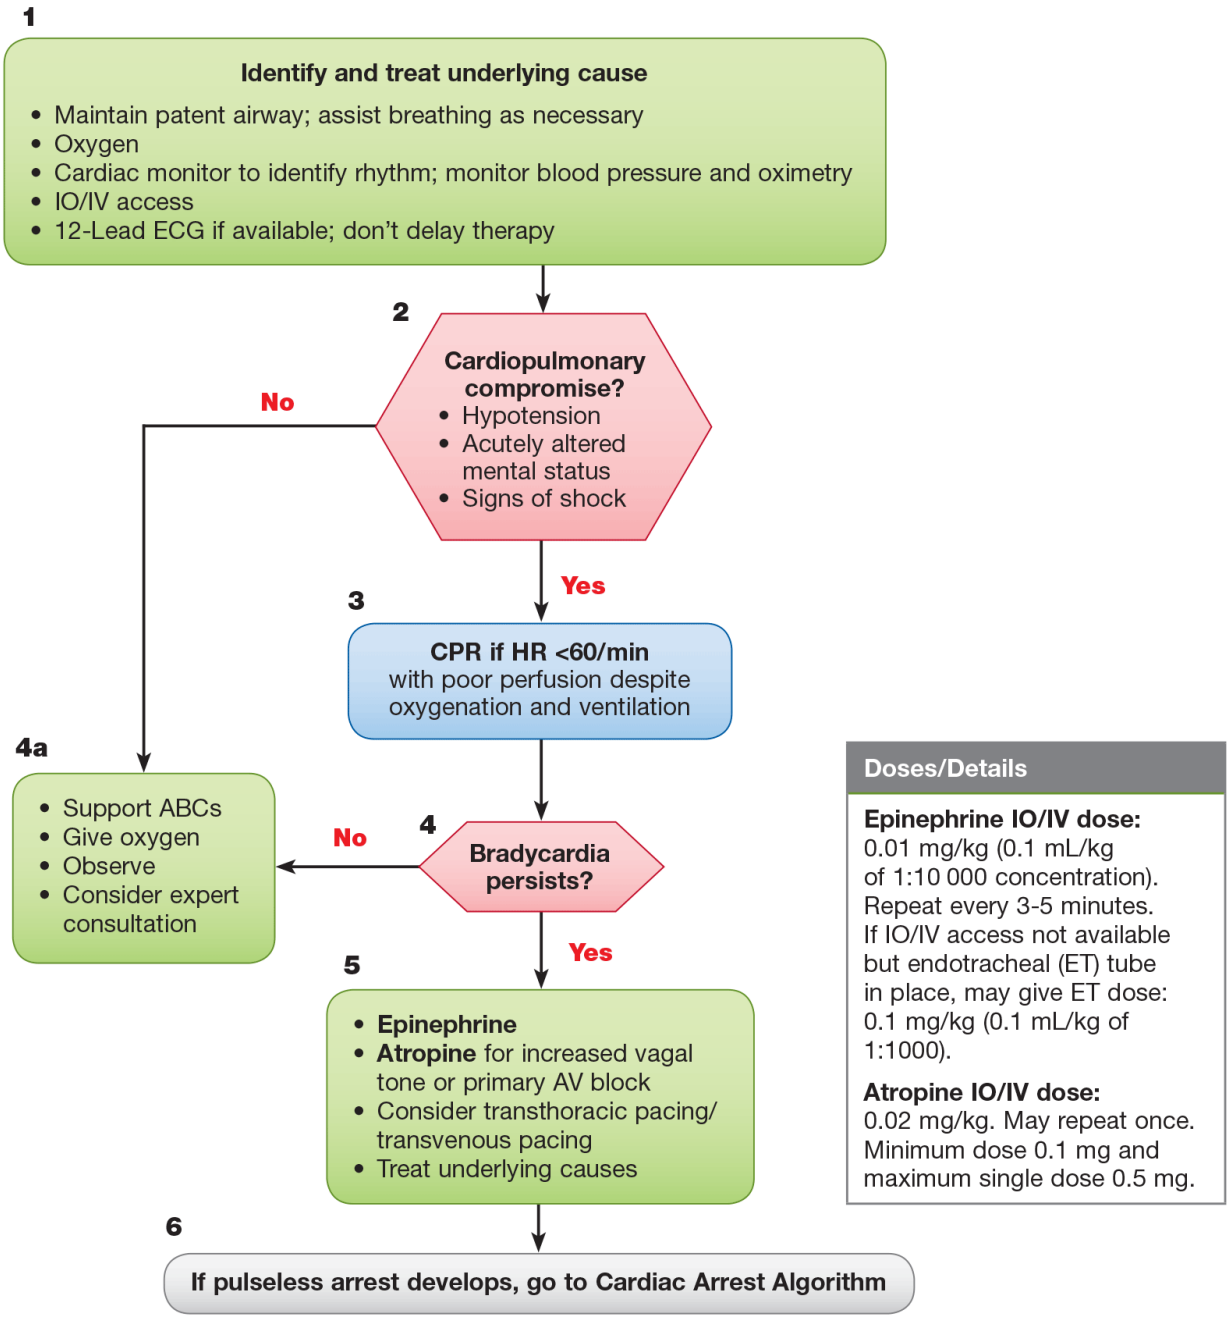
Reversible Causes

- **H**ypovolemia
- **H**ypoxia
- **H**ydrogen ion (acidosis)
- **H**ypoglycemia
- **H**ypo-/hyperkalemia
- **H**ypothermia
- **T**ension pneumothorax
- **T**amponade, cardiac
- **T**oxins
- **T**hrombosis, pulmonary
- **T**hrombosis, coronary

V. PEDIATRIC GUIDELINES

7. Pediatric Bradycardia

Pediatric Bradycardia With a Pulse and Poor Perfusion Algorithm



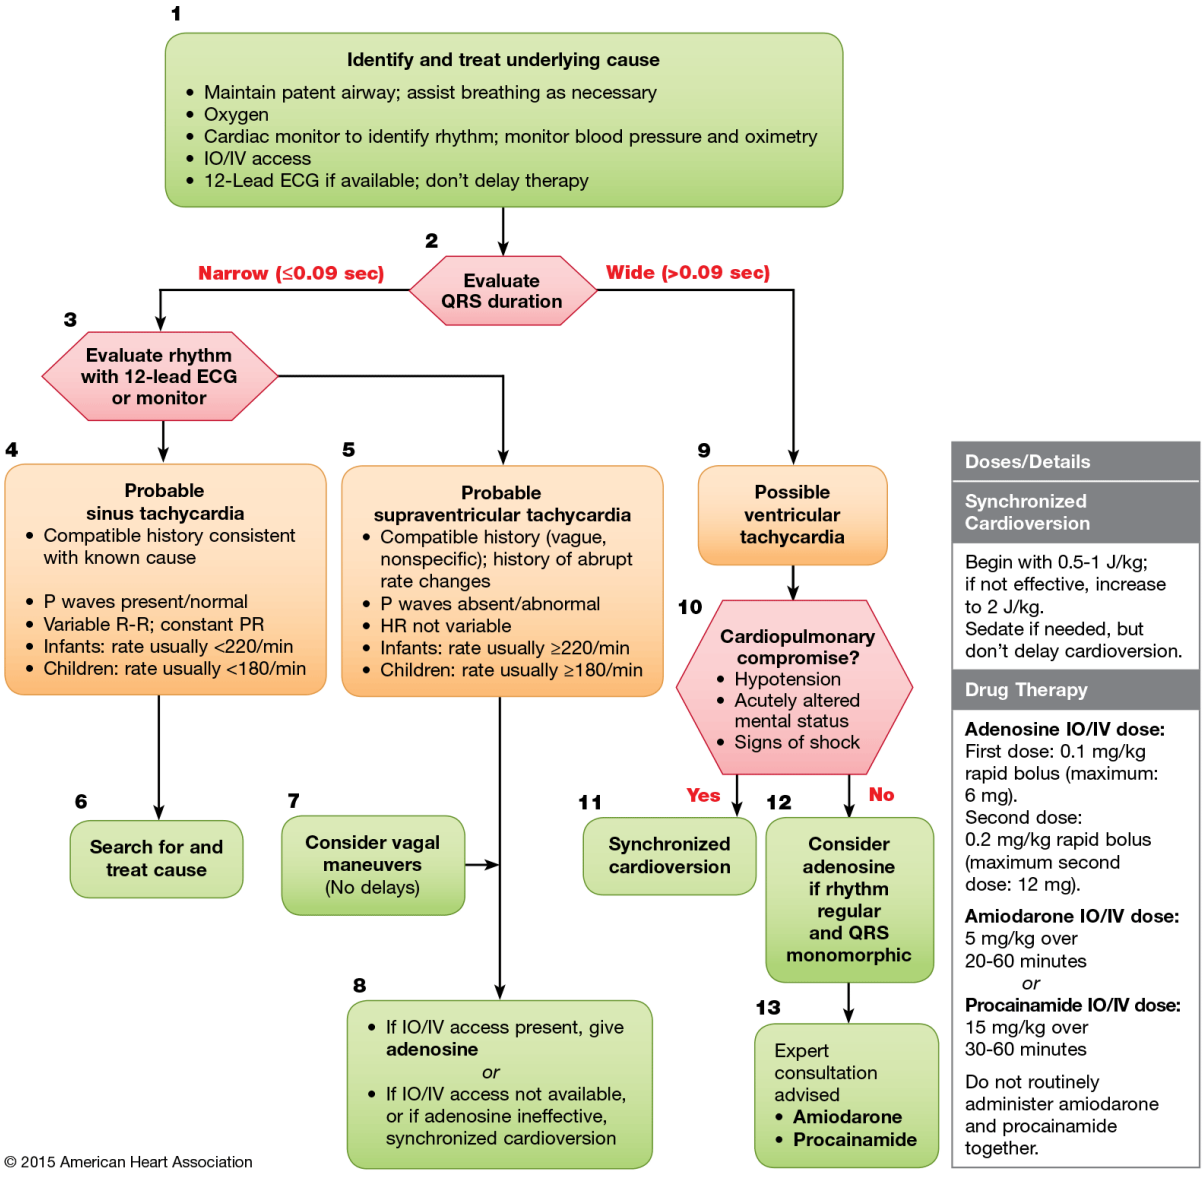
1
Identify and treat underlying cause
• Maintain patent airway; assist breathing as necessary
• Oxygen
• Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
• IO/IV access
• 12-Lead ECG if available; don't delay therapy
2
Cardiopulmonary compromise?
• Hypotension
• Acutely altered mental status
• Signs of shock
No
Yes
3
CPR if HR <60/min with poor perfusion despite oxygenation and ventilation
4
Bradycardia persists?
No
Yes
4a
• Support ABCs
• Give oxygen
• Observe
• Consider expert consultation
5
• Epinephrine
• Atropine for increased vagal tone or primary AV block
• Consider transthoracic pacing/ transvenous pacing
• Treat underlying causes
6
If pulseless arrest develops, go to Cardiac Arrest Algorithm
Doses/Details
Epinephrine IO/IV dose:
0.01 mg/kg (0.1 mL/kg of 1:10 000 concentration). Repeat every 3-5 minutes. If IO/IV access not available but endotracheal (ET) tube in place, may give ET dose: 0.1 mg/kg (0.1 mL/kg of 1:1000).
Atropine IO/IV dose:
0.02 mg/kg. May repeat once. Minimum dose 0.1 mg and maximum single dose 0.5 mg.

© 2015 American Heart Association

V. PEDIATRIC GUIDELINES

8. Pediatric Tachycardia

Pediatric Tachycardia With a Pulse and Poor Perfusion Algorithm



1
Identify and treat underlying cause
• Maintain patent airway; assist breathing as necessary
• Oxygen
• Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
• IO/IV access
• 12-Lead ECG if available; don't delay therapy
2
Evaluate QRS duration
Narrow (≤0.09 sec)
Wide (>0.09 sec)
3
Evaluate rhythm with 12-lead ECG or monitor
4
Probable sinus tachycardia
• Compatible history consistent with known cause
• P waves present/normal
• Variable R-R; constant PR
• Infants: rate usually <220/min
• Children: rate usually <180/min
5
Probable supraventricular tachycardia
• Compatible history (vague, nonspecific); history of abrupt rate changes
• P waves absent/abnormal
• HR not variable
• Infants: rate usually ≥220/min
• Children: rate usually ≥180/min
9
Possible ventricular tachycardia
10
Cardiopulmonary compromise?
• Hypotension
• Acutely altered mental status
• Signs of shock
Yes
No
6
Search for and treat cause
7
Consider vagal maneuvers (No delays)
8
• If IO/IV access present, give adenosine
or
• If IO/IV access not available, or if adenosine ineffective, synchronized cardioversion
11
Synchronized cardioversion
12
Consider adenosine if rhythm regular and QRS monomorphic
13
Expert consultation advised
• Amiodarone
• Procainamide
Doses/Details
Synchronized Cardioversion
Begin with 0.5-1 J/kg; if not effective, increase to 2 J/kg.
Sedate if needed, but don't delay cardioversion.
Drug Therapy
Adenosine IO/IV dose:
First dose: 0.1 mg/kg rapid bolus (maximum: 6 mg).
Second dose: 0.2 mg/kg rapid bolus (maximum second dose: 12 mg).
Amiodarone IO/IV dose:
5 mg/kg over 20-60 minutes
or
Procainamide IO/IV dose:
15 mg/kg over 30-60 minutes
Do not routinely administer amiodarone and procainamide together.
© 2015 American Heart Association

VI. ***TACTICAL COMBAT CASUALTY CARE (TCCC)***

1. Abbreviated TCCC Guidelines 142
2. Care Under Fire Algorithm 147
3. Tactical Field Care Algorithms 148
4. Tactical Evacuation Care Algorithms 159
5. Blood Administration and Protocol 171
6. DD1380 TCCC Card 176
7. Triage Categories 178
8. 9 – Line / MIST Report 179

VI. TACTICAL COMBAT CASUALTY CARE (TCCC)

1. Abbreviated TCCC Guidelines

Basic Management Plan for Care Under Fire

Return Fire and take cover

Direct or expect casualty to remain engaged as a combatant if appropriate

Direct casualty to move to cover and apply self-aid if able.

Try to keep the casualty from sustaining additional wounds.

Stop life-threatening external hemorrhage if tactically feasible:
- Direct casualty to control hemorrhage by self-aid if able.

Use a CoTCCC-recommended limb tourniquet for extremity hemorrhage
- Move the casualty to cover

Airway management is generally best deferred until the Tactical Field Care phase.

Basic Management Plan for Tactical Field Care

Establish Security Perimeter IAW Tactical SOPs. Maintain situational awareness.

Triage Casualties as required. Altered mental status is criteria to have weapons cleared/secured, communications gear secured and sensitive items redistributed.

Massive Hemorrhage

Assess for unrecognized hemorrhage and control all life-threatening bleeding.

Use one or more CoTCCC-recommended limb tourniquets if necessary.

Use a CoTCCC approved hemostatic dressing for compressible hemorrhage not amenable to limb tourniquet use.

Immediately apply a CoTCCC-recommended junctional tourniquet if the bleeding site is amenable to use of a junctional tourniquet.

Airway Management

Unconscious casualty without airway obstruction:
- -Chin lift or jaw thrust maneuver
- -Nasopharyngeal airway
- -Place the casualty in the recovery position

Casualty with airway obstruction or impending airway obstruction:
- -Allow a conscious casualty to assume any position that best protects the airway, to include sitting up
- -Chin lift or jaw thrust maneuver
- -Nasopharyngeal airway
- -Place an unconscious casualty in the recovery position

If the previous measures are unsuccessful perform a surgical cricothyroidotomy using one of the following:
- -CricKey technique
- -Bougie-aided open surgical technique
- -Standard open surgical technique

*Use lidocaine if the casualty is conscious

Basic Management Plan for Tactical Field Care continued

Respiration/Breathing

In a casualty with progressive respiratory distress and known or suspected torso trauma, consider a tension pneumothorax:

-Decompress the chest on the side of the injury at the primary or alternate site.

All open and/or sucking chest wounds should be treated by:

-Applying a vented chest seal (preferred)

-Applying a non-vented chest seal

-Burp the wound if indicated for breathing difficulty

Initiate pulsoximetry monitoring.

Monitor for tension pneumothorax.

Casualties with moderate/severe TBI should be given supplemental oxygen when available to maintain an oxygen saturation > 90%.

Circulation - Bleeding

Apply a pelvic binder for suspected pelvic fracture and/or severe blunt force or blast injury.

Reassess prior tourniquet application:

-Expose the wound and determine if a tourniquet is needed; if bleeding is not controlled then tighten tourniquet if possible.

-If the first tourniquet does not control bleeding after tightening, then add a second tourniquet side-by-side with the first.

Convert Limb tourniquets and junctional tourniquets if the following three criteria are met:

-The casualty is not in shock.

-It is possible to monitor the wound closely for bleeding.

-The tourniquet is not being used to control bleeding from an amputation.

Convert tourniquets in less than 2 hours if bleeding can be controlled with other means.

Expose and use an indelible marker to clearly mark all tourniquet sites with the time of tourniquet application, reapplication, conversion, or removal.

Circulation - IV/IO Access

Start an 18-gauge IV or Saline Lock if indicated.

If IV access is not obtainable, use an intraosseous (IO) needle.

Circulation - TXA

If a casualty is anticipated to need a blood transfusion, then administer 1 gram of tranexamic acid (TXA) in 100ml of NS or LR over 10min ASAP but NOT beyond 3 hours post injury.

Circulation - Fluid Resuscitation

Assess for hemorrhagic shock:

-If not in shock PO fluids are permissible if casualty is conscious and can swallow.

-If in shock resuscitate with:

Whole blood (preferred) or
Plasma, RBCs and platelets (1:1:1) or
Plasma and RBCs (1:1) or
Plasma or if blood products not available,
Hextend or Lactated Ringers or Plasma-Lyte-A

Resuscitate with above fluids until a palpable radial pulse, improved mental status or systolic BP of 80-90 mmHg is present. Discontinue fluids when one or more end points are achieved.

Reassess casualty frequently to check for recurrence of shock. If shock recurs, verify all hemorrhage is under control and repeat fluid resuscitation as above.

Basic Management Plan for Tactical Field Care continued

Hypothermia Prevention

Minimize casualty environmental exposure and promote heat retention.
Keep personal protective gear on if feasible. Replace wet clothing if possible. Get casualty onto insulated surface ASAP.
Use a hypothermia prevention kit with active rewarming.
If none above is available, then use dry blankets, poncho liners, or sleeping bags and keep the casualty warm and dry.
Warm IV fluids are preferred.

Penetrating Eye Trauma - If penetrating eye injury is noted or suspected:

Perform a rapid field test of visual acuity and document findings.
Cover eye with a rigid eye shield (not a pressure patch).
Administer Combat Wound Medication Pack if possible and/or administer IV/IM antibiotics per below.

Monitoring – Initiate advanced electronic monitoring of vital signs if available.

Analgesia/Pain Management

Analgesia on the battlefield should generally be achieved by one of three options:
Mild to Moderate Pain and/or Casualty can swallow and is still able to fight:
-Administer TCCC Combat Wound Medication Pack (CWMP)
Moderate to Severe Pain and casualty IS NOT in Shock
-Oral Transmucosal Fentanyl Citrate (OTFC) 800mcg
Moderate to Severe Pain and casualty is in hemorrhagic shock or respiratory distress
-Administer Ketamine 50mg IM or IN repeating q30min prn
OR
-Administer Ketamine 20mg Slow IV or IO repeating q20min prn

*Endpoint control of pain or development of nystagmus.
*Consider Ondansetron 4mg ODT/IV/IO/IM q8hours prn for nausea and vomiting.

Antibiotics

If able to take PO, then administer Moxifloxacin 400mg PO qDaily from CWPP.
If unable to take PO, administer Ertapenem 1 gram IV/IM qDaily.

Wounds

Inspect and dress known wounds.
Check for Additional Wounds.

Burns

Facial burns should be aggressively monitored for airway status and potential inhalation injury.
Estimate total body surface area (TBSA) burned to nearest 10%.
Cover burned areas with dry, sterile dressings. For burns >20% TBSA, consider placing casualty immediately in HPMK or other hypothermia prevention means.
Fluid Resuscitation (USAISR Rule of Ten):
-If burns >20% TBSA, initiate IV/IO fluids ASAP with Lactated Ringers, NS, or Hextend. If Hextend, then no more than 1000ml followed by LR or NS as needed.
-Initial IV/IO fluid rate = %TBSA X 10ml/per hour for adults 40-80 kg (+100ml/hr for every 10kg above 80kg).
-If hemorrhagic shock is present then resuscitate IAW fluid resuscitation in Circulation section.
All TCCC interventions may be performed on or through burned skin.

Basic Management Plan for Tactical Field Care continued

Splinting - Splint Fractures and Recheck Pulses.

Communication

- Communicate with the casualty if possible. Encourage, reassure, and explain care.
- Communicate with tactical leadership ASAP and throughout treatment. Provide casualty status and evac requirements.
- Communicate with the evacuation system to arrange TACEVAC.
- Communicate with medical personnel on evacuation assets and relay mechanism of injury, injuries sustained, signs/symptoms and treatments rendered.

Documentation

Document clinical assessments, treatments rendered, and changes in the casualty's status on a TCCC Casualty Card (DD Form 1380) and forward this information with the casualty to the next level of care.

Cardiopulmonary resuscitation (CPR)

- Battlefield blast or penetrating trauma casualties with no pulse, no ventilations, and no other signs of life should not be resuscitated.
- Casualties with torso trauma or polytrauma with no pulse or respirations should have bilateral needle decompression performed to confirm/deny tension pneumothorax prior to discontinuing care.

Prepare for Evacuation

- Complete and secure TCCC Card (DD1380) to casualty.
- Secure all loose ends of bandages and wraps.
- Secure hypothermia prevention wraps/blankets/straps.
- Secure litter straps and consider additional padding for long evacuations.
- Provide instructions to ambulatory patients as needed.
- Stage Casualties for evacuation.
- Maintain security at evacuation site.

Basic Management Plan for Tactical Evacuation Care (TACEVAC)

In addition to the principles of Tactical Field Care consider the following for Tactical Evacuation Care:

Transition of Care

Tactical force should establish evacuation point security and stage casualties for evacuation.
Tactical force personnel/medic should communicate patient status to TACEVAC personnel to include stable/unstable, injuries identified, and treatments rendered.
TACEVAC personnel stage casualties on evac platform as required.
Secure casualties on evac platform IAW unit policies, platform configurations, and safety requirements.
TACEVAC medical personnel reassess casualties and re-evaluate all injuries and interventions.

Airway Management- Consider the following for casualty with airway obstruction or impending airway obstruction:

-Supraglottic airway, or
-Endotracheal intubation

Breathing

Consider chest tube insertion if no improvement and/or long transport is anticipated.
Administer oxygen when possible for the following types of casualties:

-Low oxygen saturation by pulse oximetry
-Injuries associated with impaired oxygenation
-Unconscious casualty
-Casualty with TBI (maintain oxygen saturation > 90%)
-Casualty in shock
-Casualty at altitude

Traumatic Brain Injury-Casualties with moderate/severe TBI should be monitored for:

-Decreases in level of consciousness
-Pupillary dilation
-SBP should be >90 mmHg
-O2 sat > 90
-Hypothermia
-PCO2 (If capnography is available, maintain between 35-40 mmHg)
-Penetrating head trauma (if present, administer antibiotics)
-Assume a spinal (neck) injury until cleared

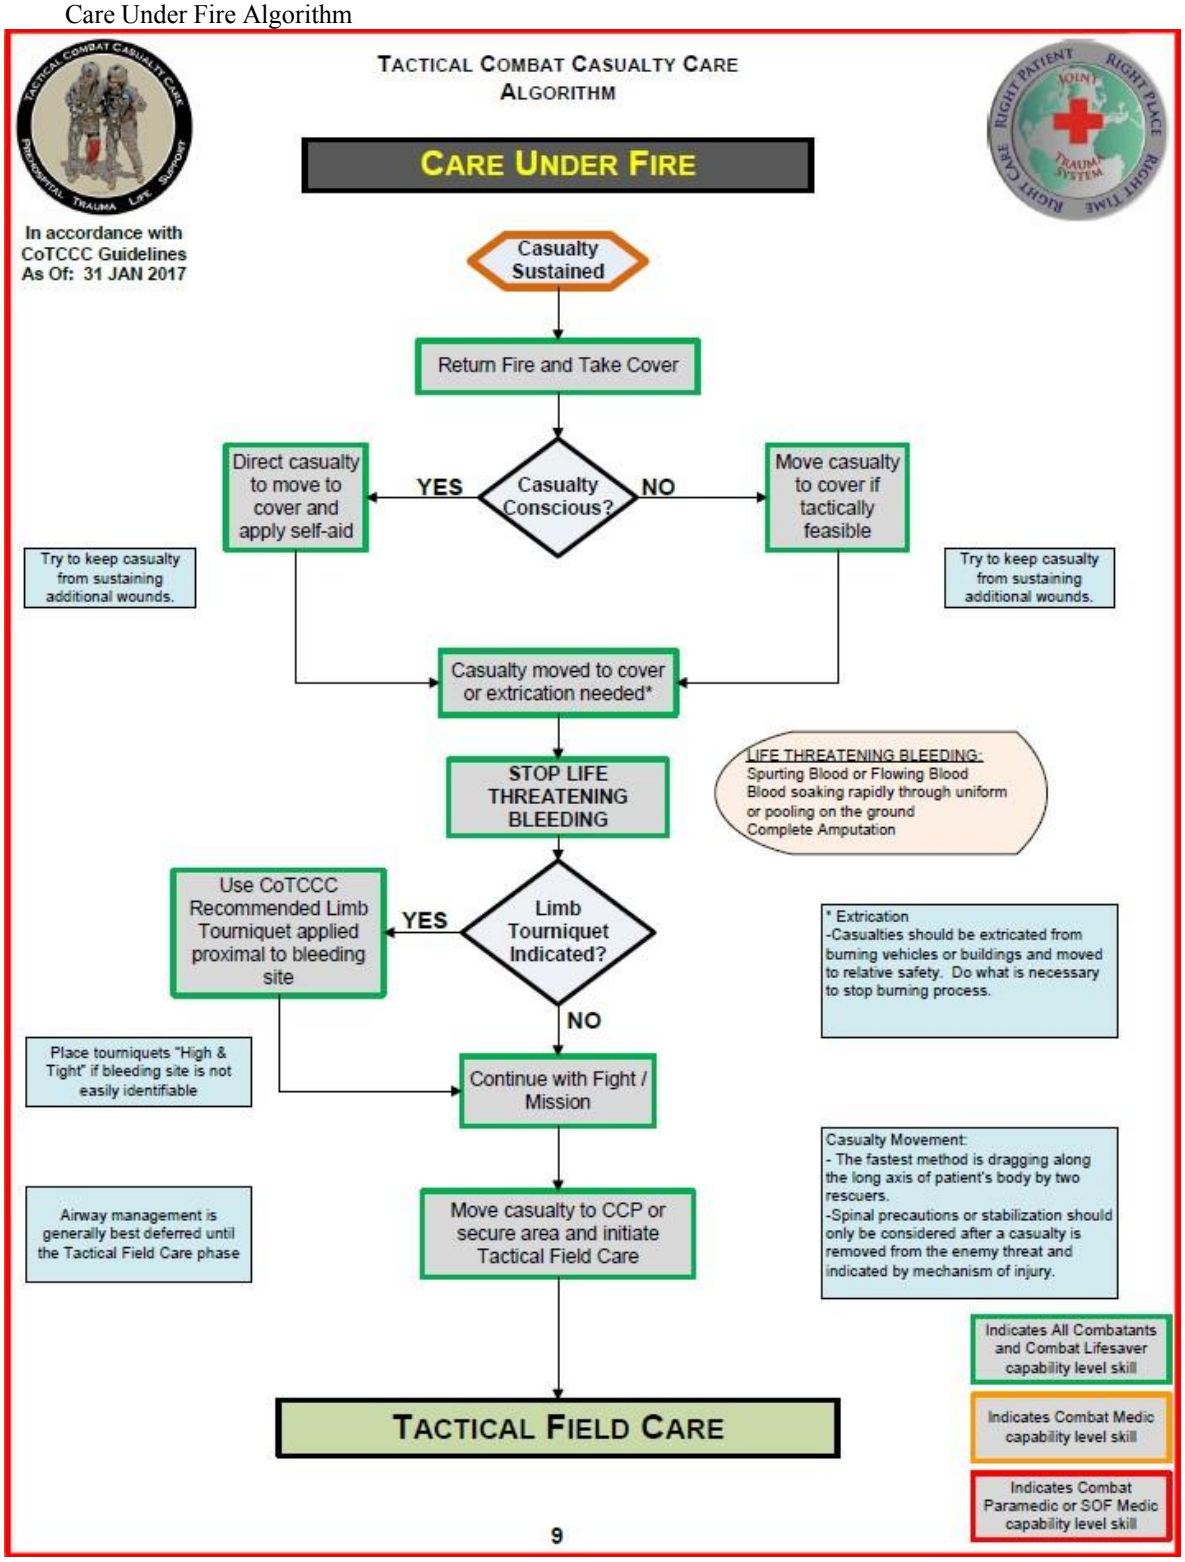
If impending herniation is suspected take the following actions:

-Administer 250 cc of 3 or 5% hypertonic saline bolus
-Elevate the casualty's head 30 degrees
-Hyperventilate the casualty

Communication

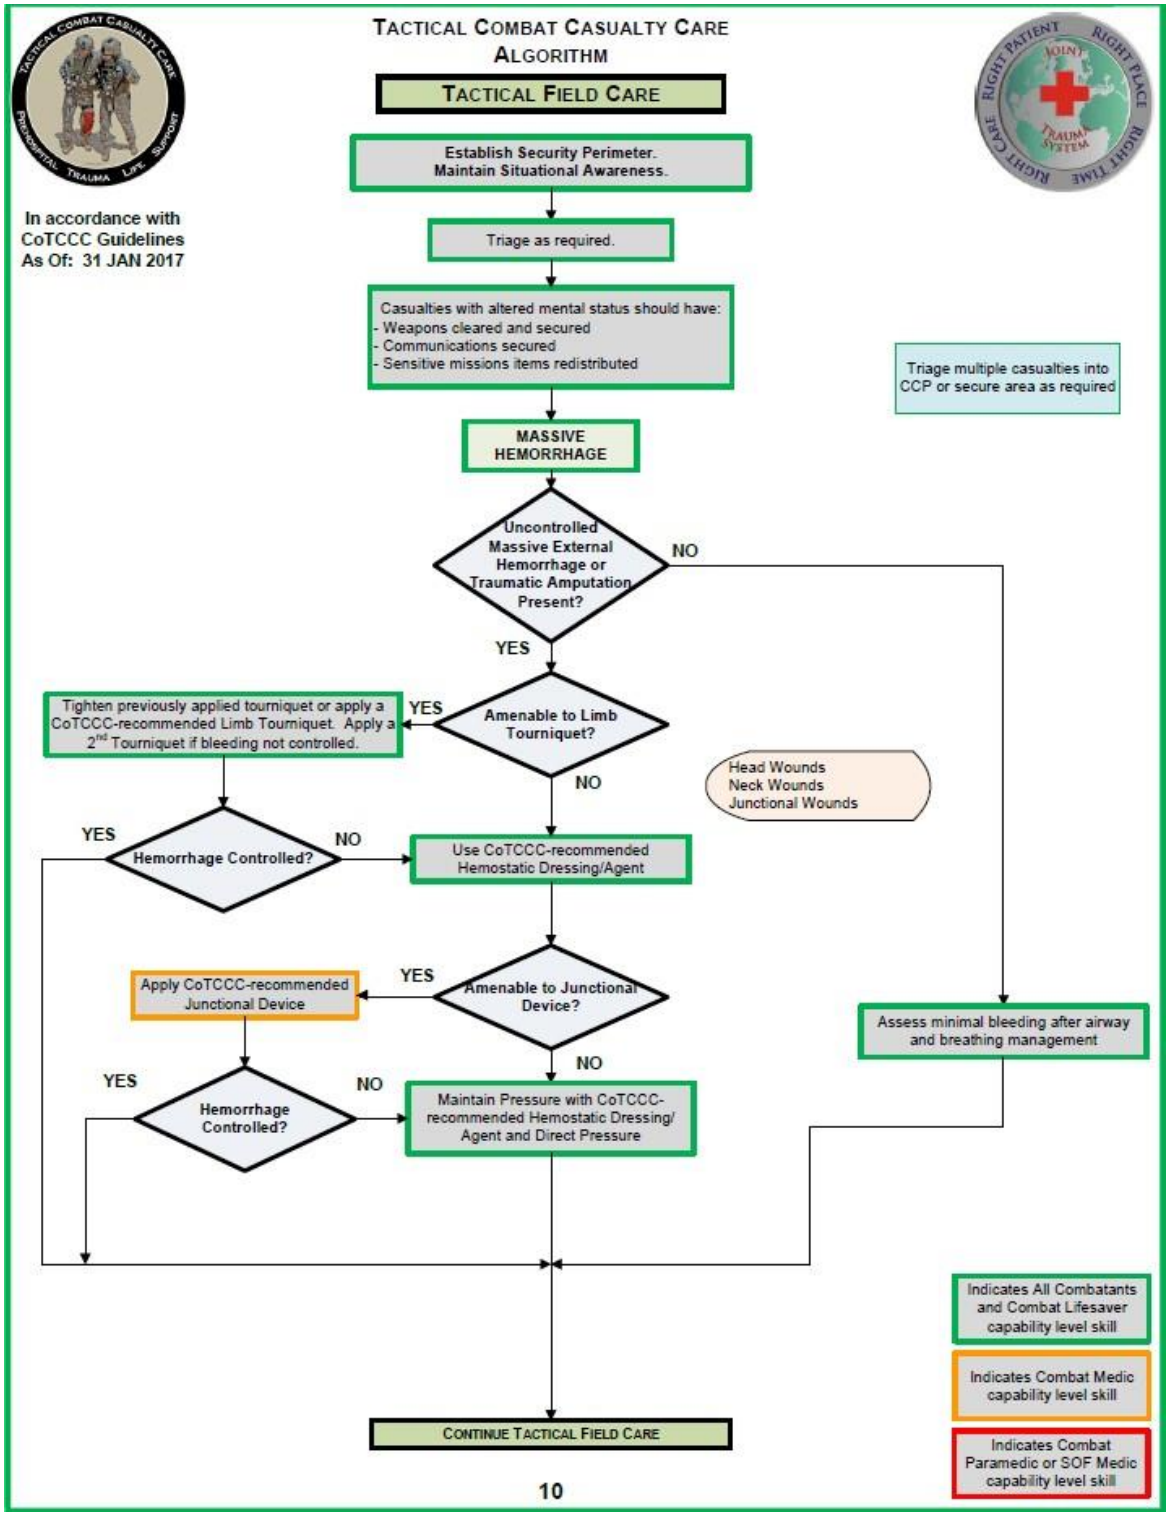
Communicate with the casualty if possible. Encourage, reassure, and explain care
Communicate with next level of care and relay mechanism of injury, injuries sustained, signs/symptoms, and treatments rendered.

2. Care Under Fire Algorithm

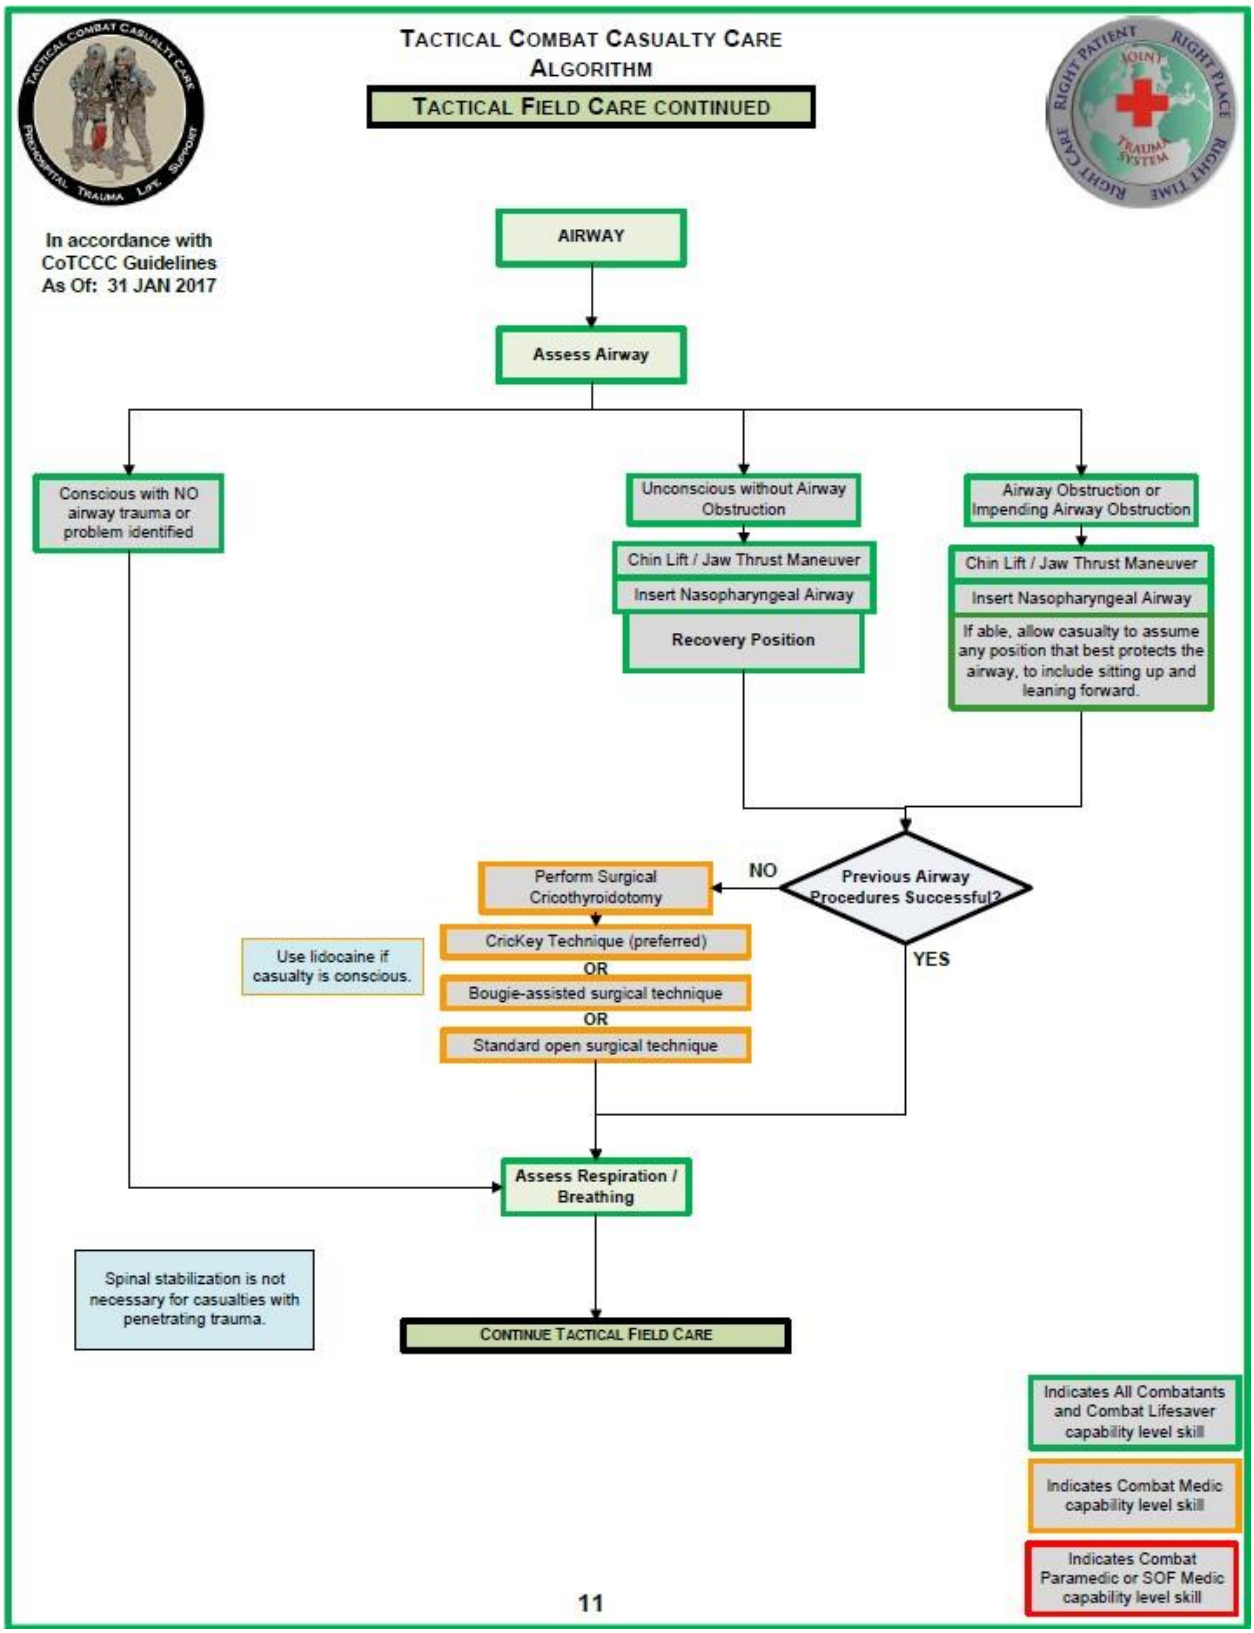


TACTICAL COMBAT CASUALTY CARE ALGORITHM
CARE UNDER FIRE
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
Casualty Sustained
Return Fire and Take Cover
Casualty Conscious?
YES
Direct casualty to move to cover and apply self-aid
NO
Move casualty to cover if tactically feasible
Try to keep casualty from sustaining additional wounds.
Try to keep casualty from sustaining additional wounds.
Casualty moved to cover or extrication needed*
STOP LIFE THREATENING BLEEDING
LIFE THREATENING BLEEDING:
Spurting Blood or Flowing Blood
Blood soaking rapidly through uniform or pooling on the ground
Complete Amputation
Limb Tourniquet Indicated?
YES
Use CoTCCC Recommended Limb Tourniquet applied proximal to bleeding site
NO
* Extrication
-Casualties should be extricated from burning vehicles or buildings and moved to relative safety. Do what is necessary to stop burning process.
Place tourniquets "High & Tight" if bleeding site is not easily identifiable
Continue with Fight / Mission
Casualty Movement:
- The fastest method is dragging along the long axis of patient's body by two rescuers.
-Spinal precautions or stabilization should only be considered after a casualty is removed from the enemy threat and indicated by mechanism of injury.
Airway management is generally best deferred until the Tactical Field Care phase
Move casualty to CCP or secure area and initiate Tactical Field Care
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
TACTICAL FIELD CARE
9

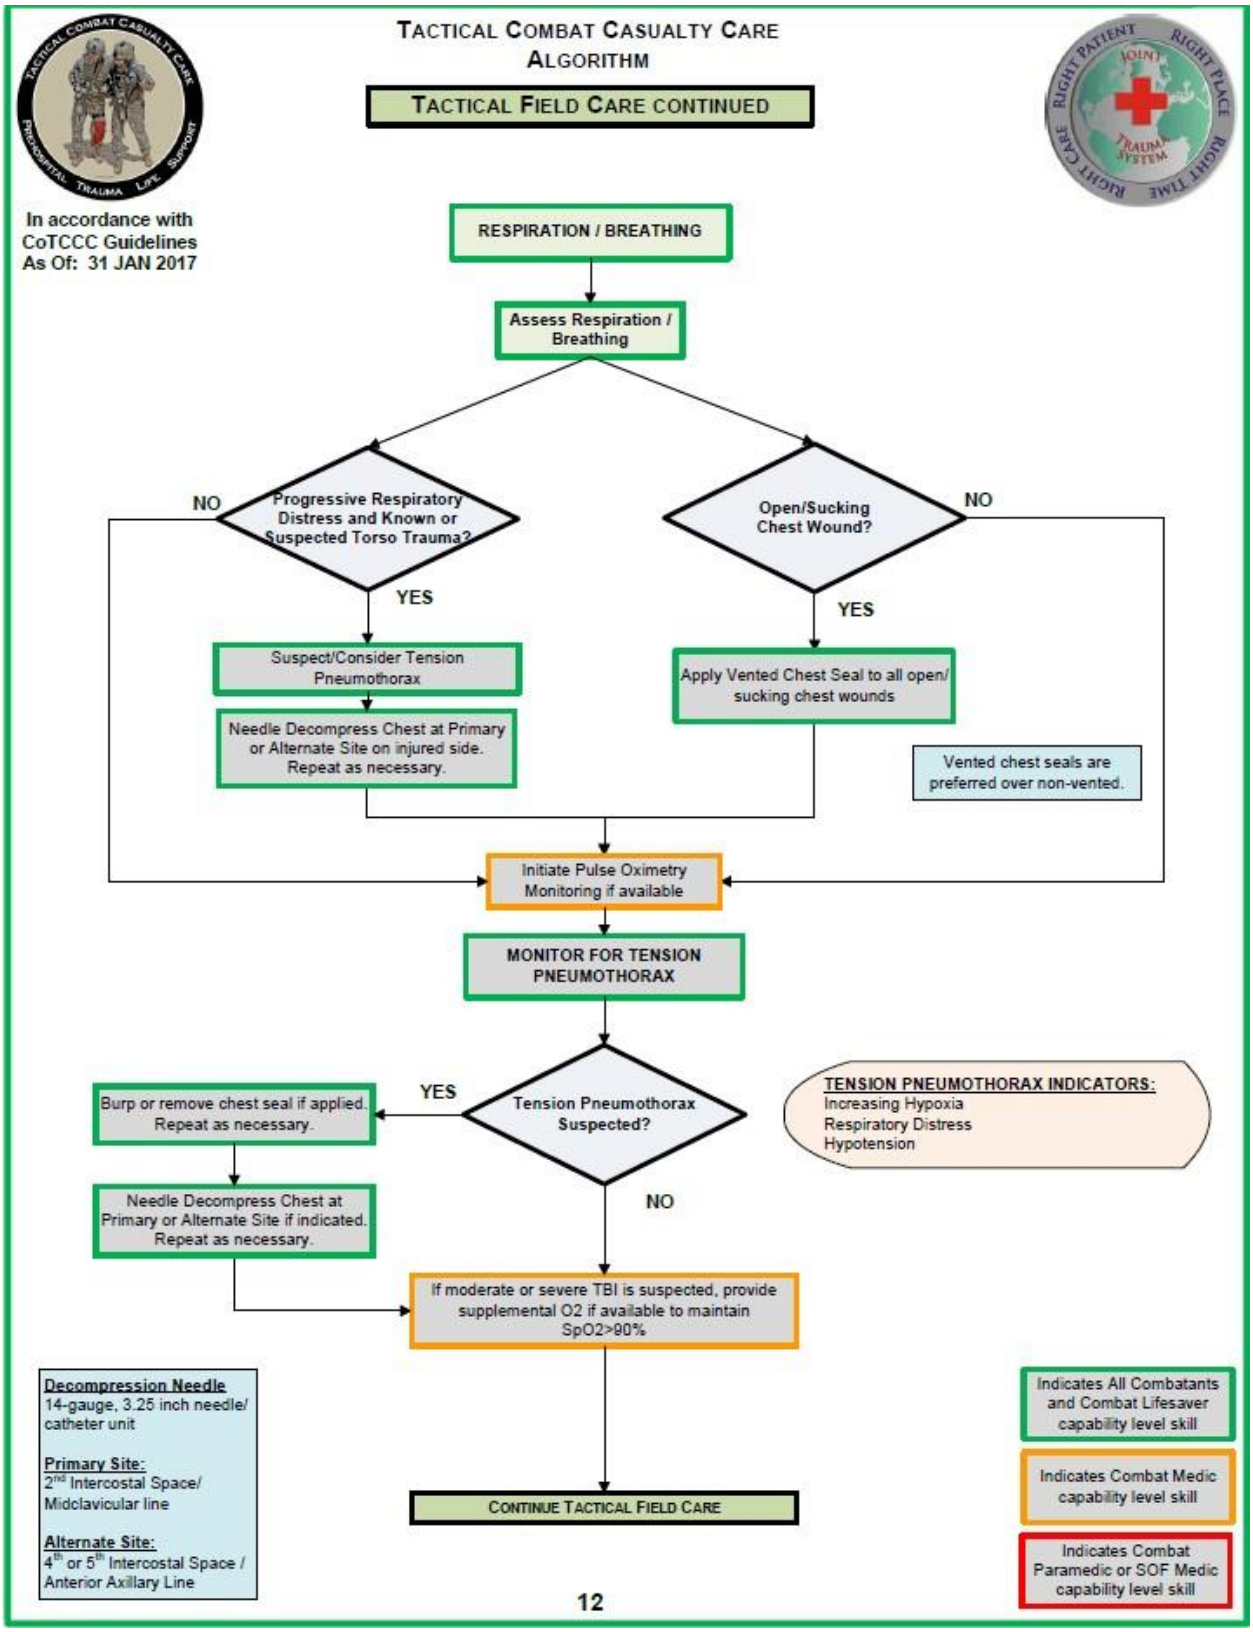
3. Tactical Field Care Algorithm



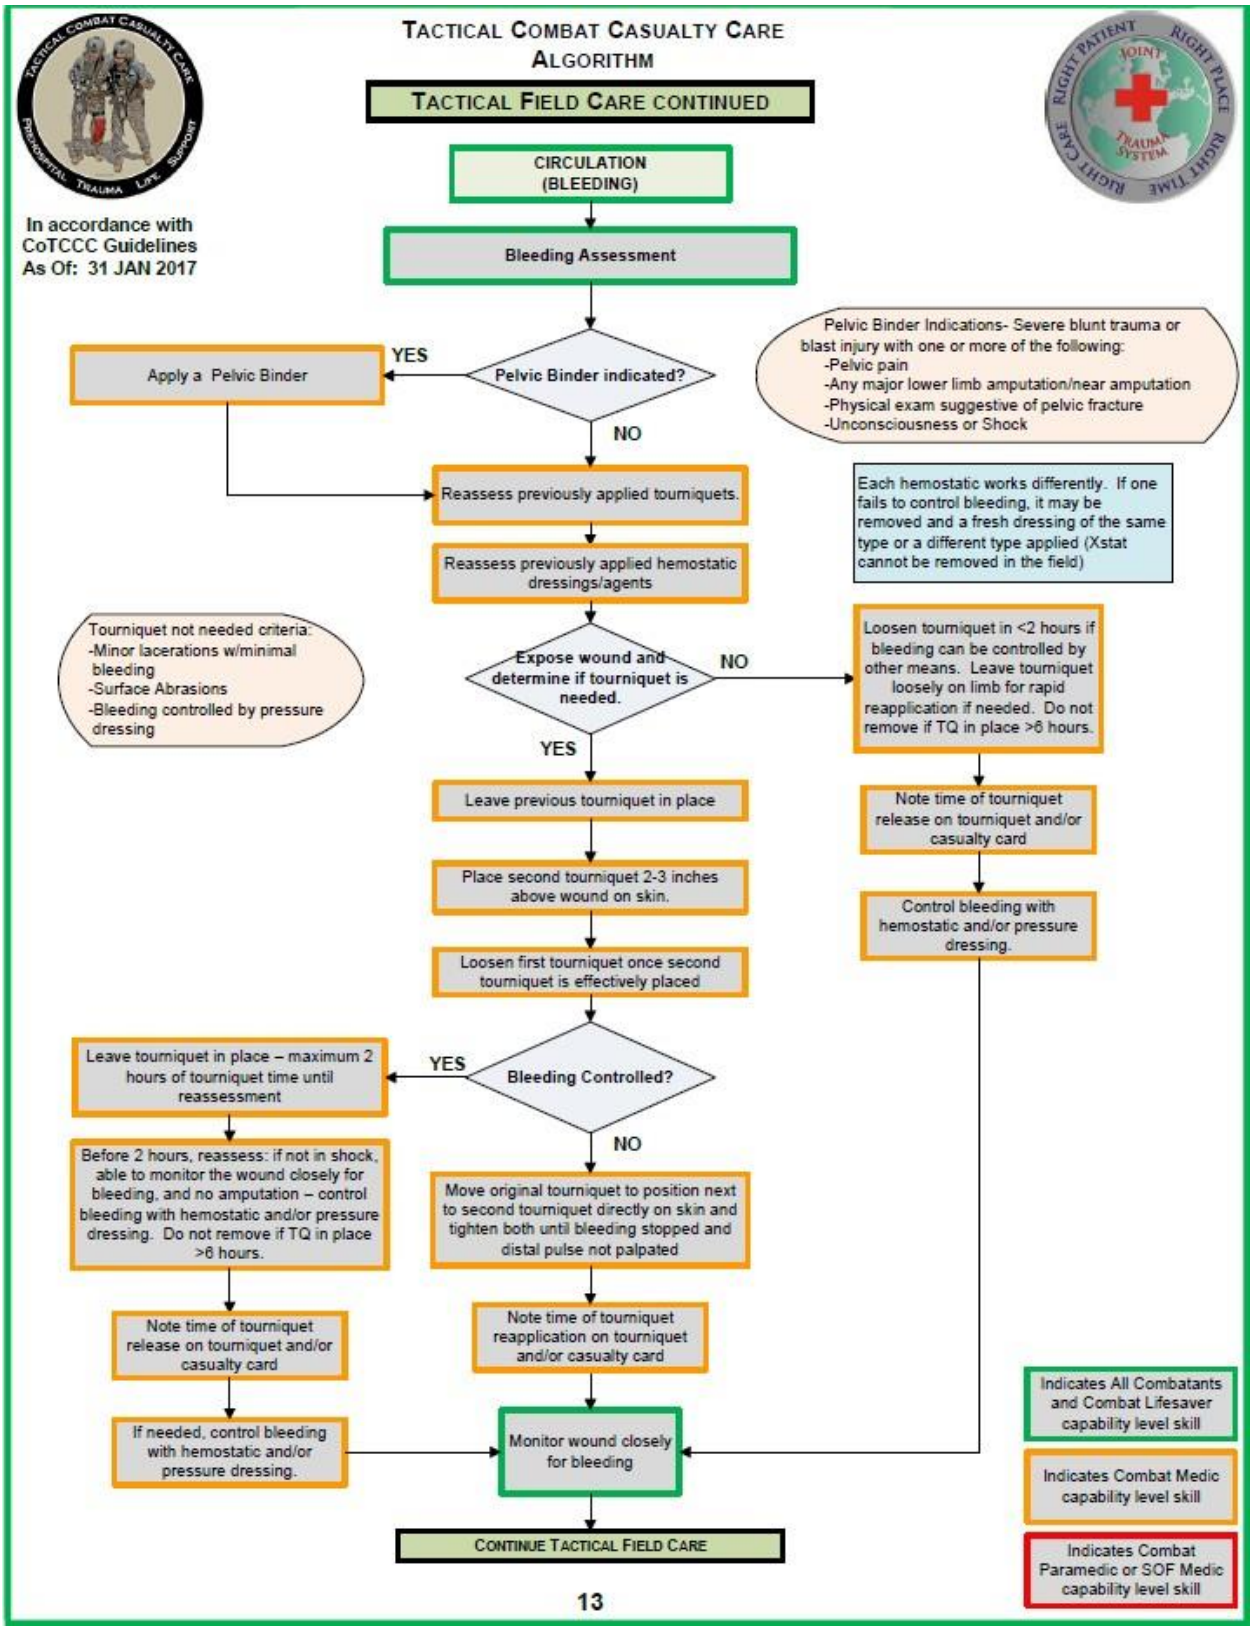
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
Establish Security Perimeter. Maintain Situational Awareness.
Triage as required.
Casualties with altered mental status should have:
- Weapons cleared and secured
- Communications secured
- Sensitive missions items redistributed
Triage multiple casualties into CCP or secure area as required
MASSIVE HEMORRHAGE
Uncontrolled Massive External Hemorrhage or Traumatic Amputation Present?
NO
YES
Amenable to Limb Tourniquet?
YES
Tighten previously applied tourniquet or apply a CoTCCC-recommended Limb Tourniquet. Apply a 2nd Tourniquet if bleeding not controlled.
NO
Head Wounds
Neck Wounds
Junctional Wounds
Hemorrhage Controlled?
YES
NO
Use CoTCCC-recommended Hemostatic Dressing/Agent
Amenable to Junctional Device?
YES
Apply CoTCCC-recommended Junctional Device
NO
Hemorrhage Controlled?
YES
NO
Maintain Pressure with CoTCCC-recommended Hemostatic Dressing/ Agent and Direct Pressure
Assess minimal bleeding after airway and breathing management
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
10



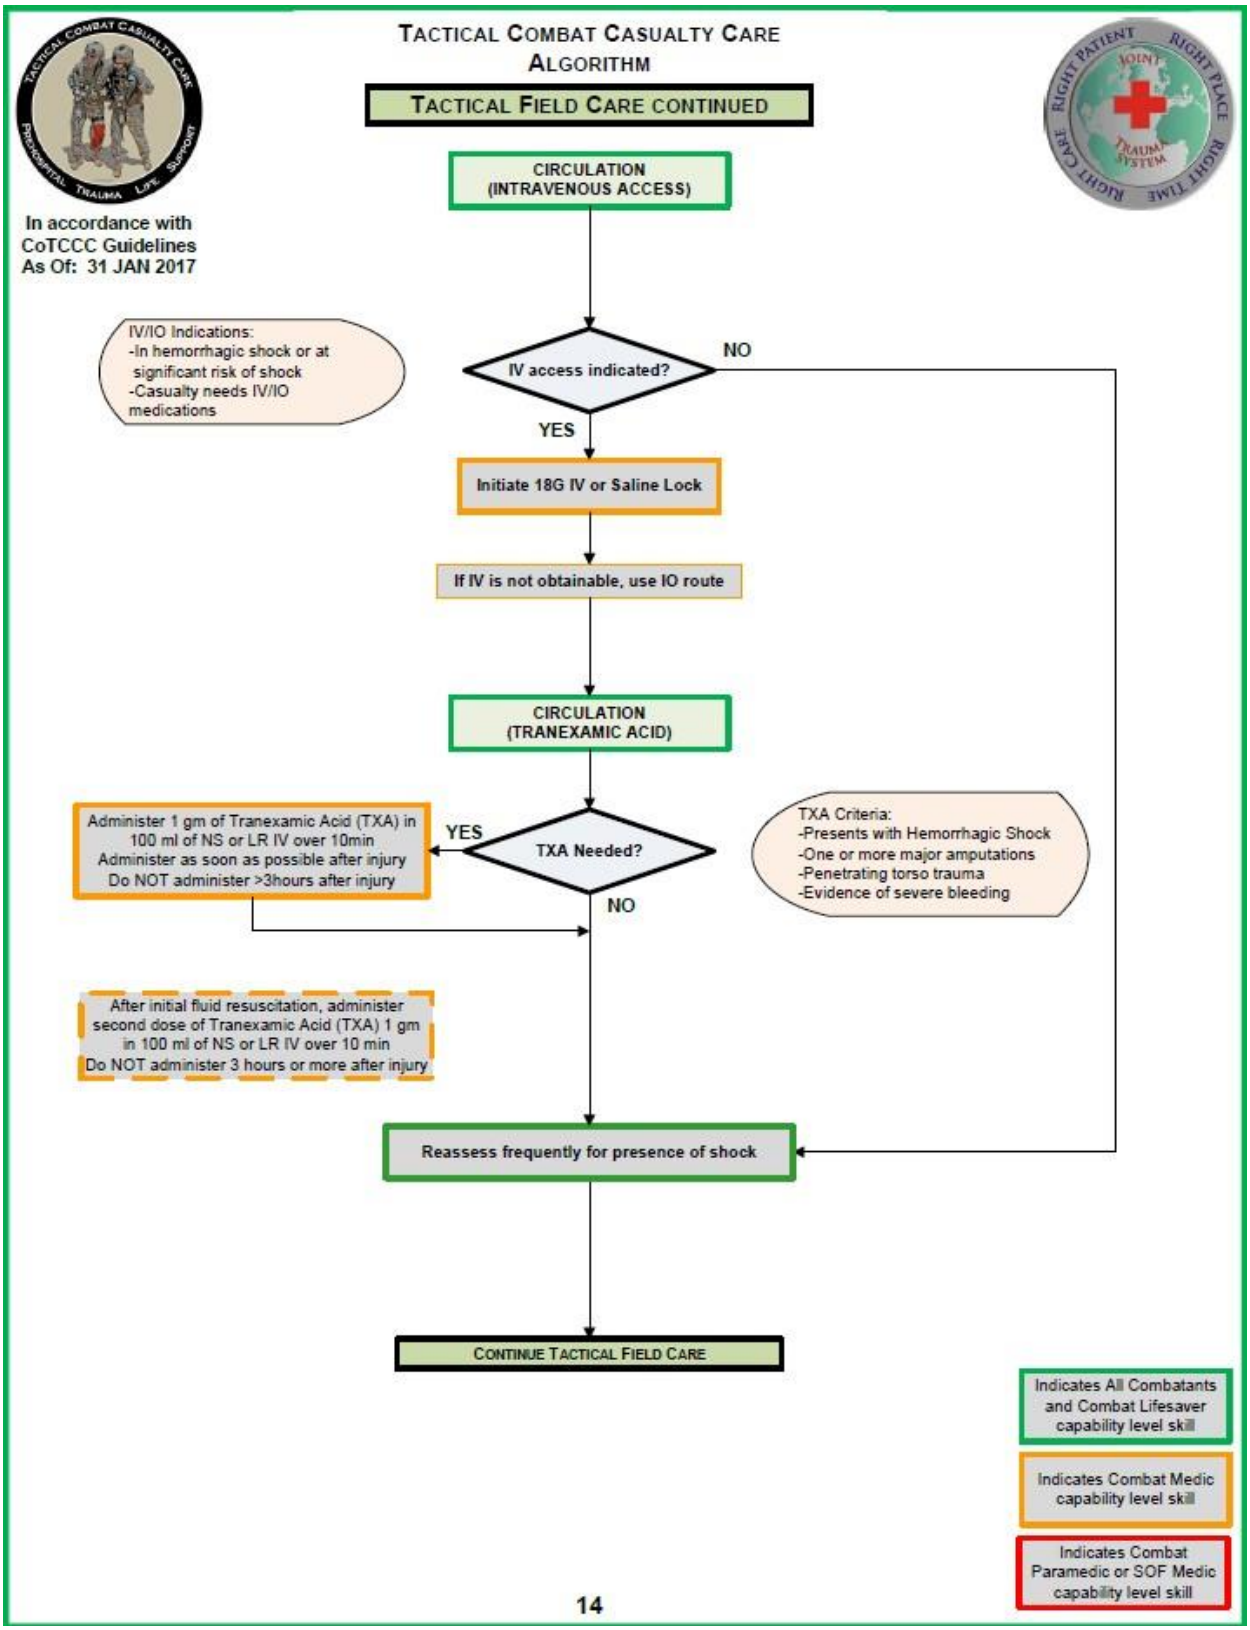
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
AIRWAY
Assess Airway
Conscious with NO airway trauma or problem identified
Unconscious without Airway Obstruction
Chin Lift / Jaw Thrust Maneuver
Insert Nasopharyngeal Airway
Recovery Position
Airway Obstruction or Impending Airway Obstruction
Chin Lift / Jaw Thrust Maneuver
Insert Nasopharyngeal Airway
If able, allow casualty to assume any position that best protects the airway, to include sitting up and leaning forward.
Previous Airway Procedures Successful?
NO
YES
Perform Surgical Cricothyroidotomy
CricKey Technique (preferred)
OR
Bougie-assisted surgical technique
OR
Standard open surgical technique
Use lidocaine if casualty is conscious.
Assess Respiration / Breathing
Spinal stabilization is not necessary for casualties with penetrating trauma.
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
11



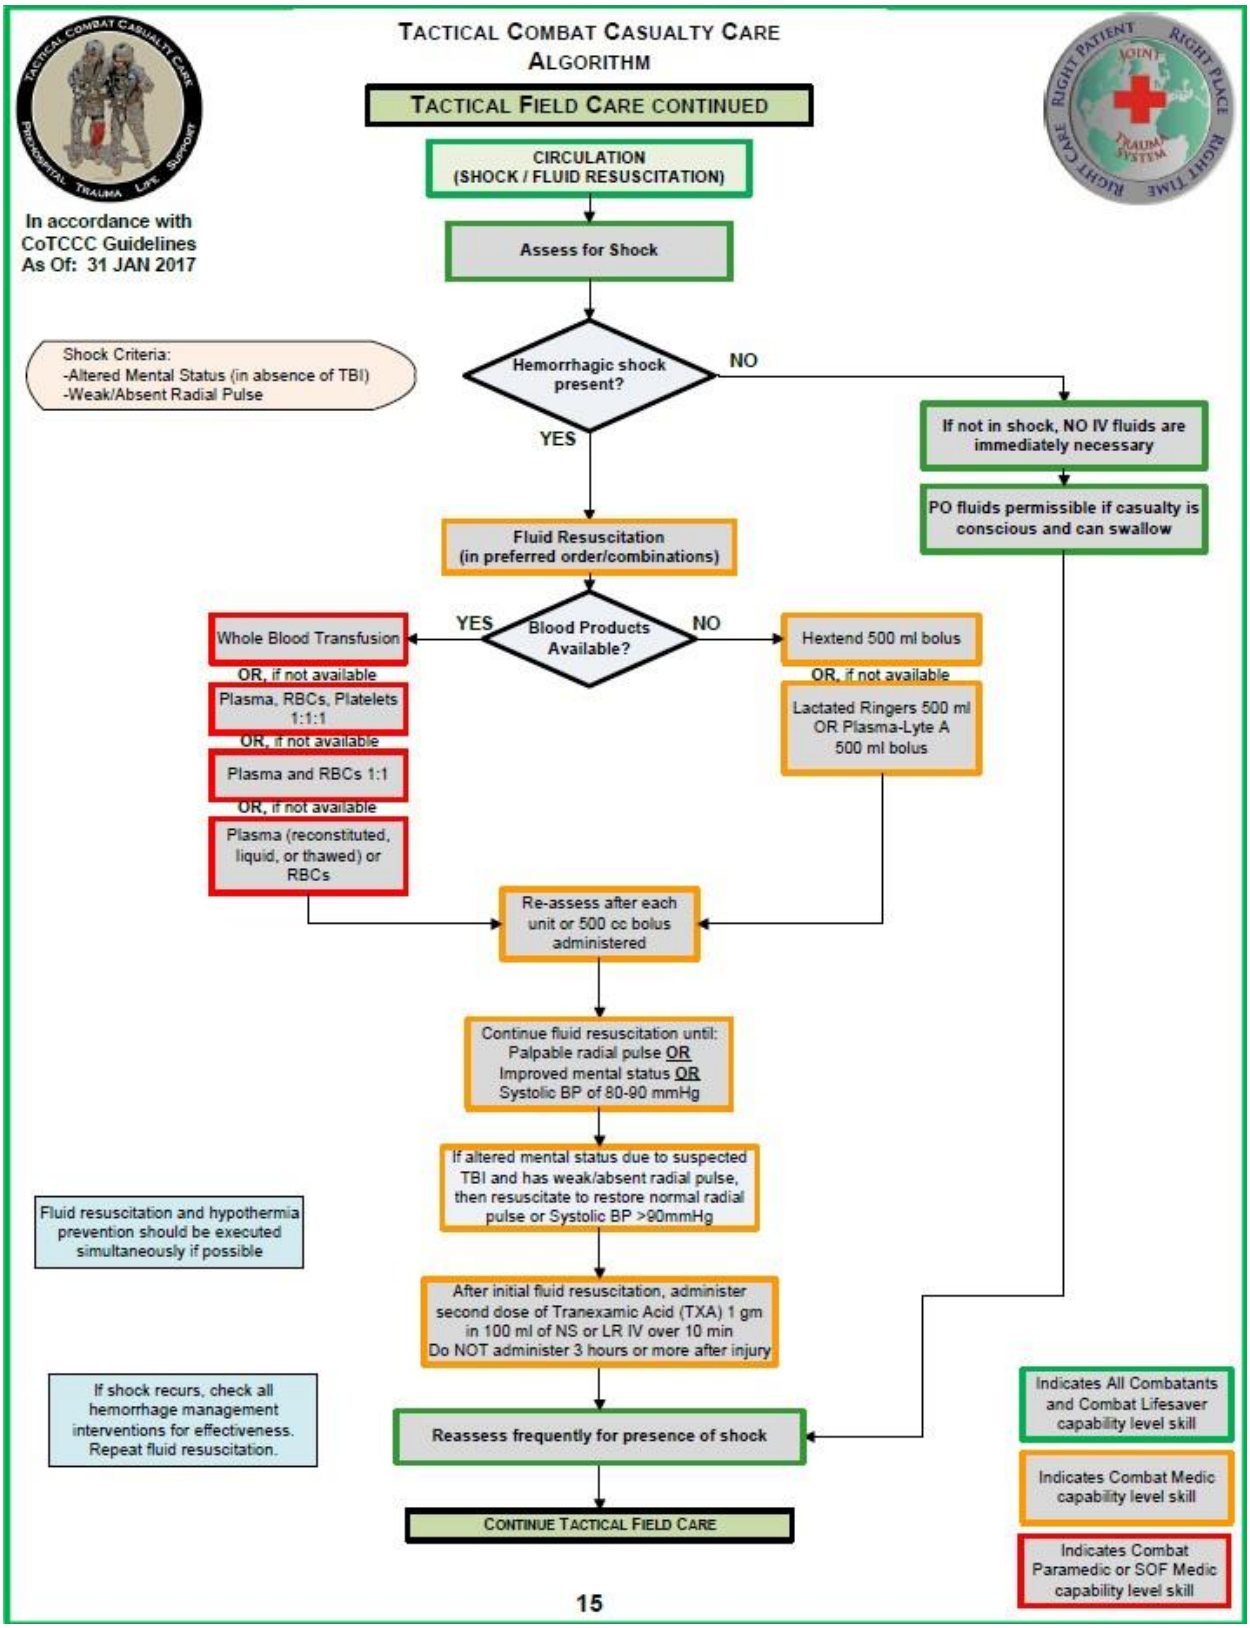
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
RESPIRATION / BREATHING
Assess Respiration / Breathing
Progressive Respiratory Distress and Known or Suspected Torso Trauma?
NO
YES
Suspect/Consider Tension Pneumothorax
Needle Decompress Chest at Primary or Alternate Site on injured side. Repeat as necessary.
Open/Sucking Chest Wound?
NO
YES
Apply Vented Chest Seal to all open/ sucking chest wounds
Vented chest seals are preferred over non-vented.
Initiate Pulse Oximetry Monitoring if available
MONITOR FOR TENSION PNEUMOTHORAX
Tension Pneumothorax Suspected?
YES
Burp or remove chest seal if applied. Repeat as necessary.
Needle Decompress Chest at Primary or Alternate Site if indicated. Repeat as necessary.
NO
TENSION PNEUMOTHORAX INDICATORS:
Increasing Hypoxia
Respiratory Distress
Hypotension
If moderate or severe TBI is suspected, provide supplemental O2 if available to maintain SpO2>90%
CONTINUE TACTICAL FIELD CARE
Decompression Needle
14-gauge, 3.25 inch needle/ catheter unit
Primary Site:
2nd Intercostal Space/ Midclavicular line
Alternate Site:
4th or 5th Intercostal Space / Anterior Axillary Line
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
12



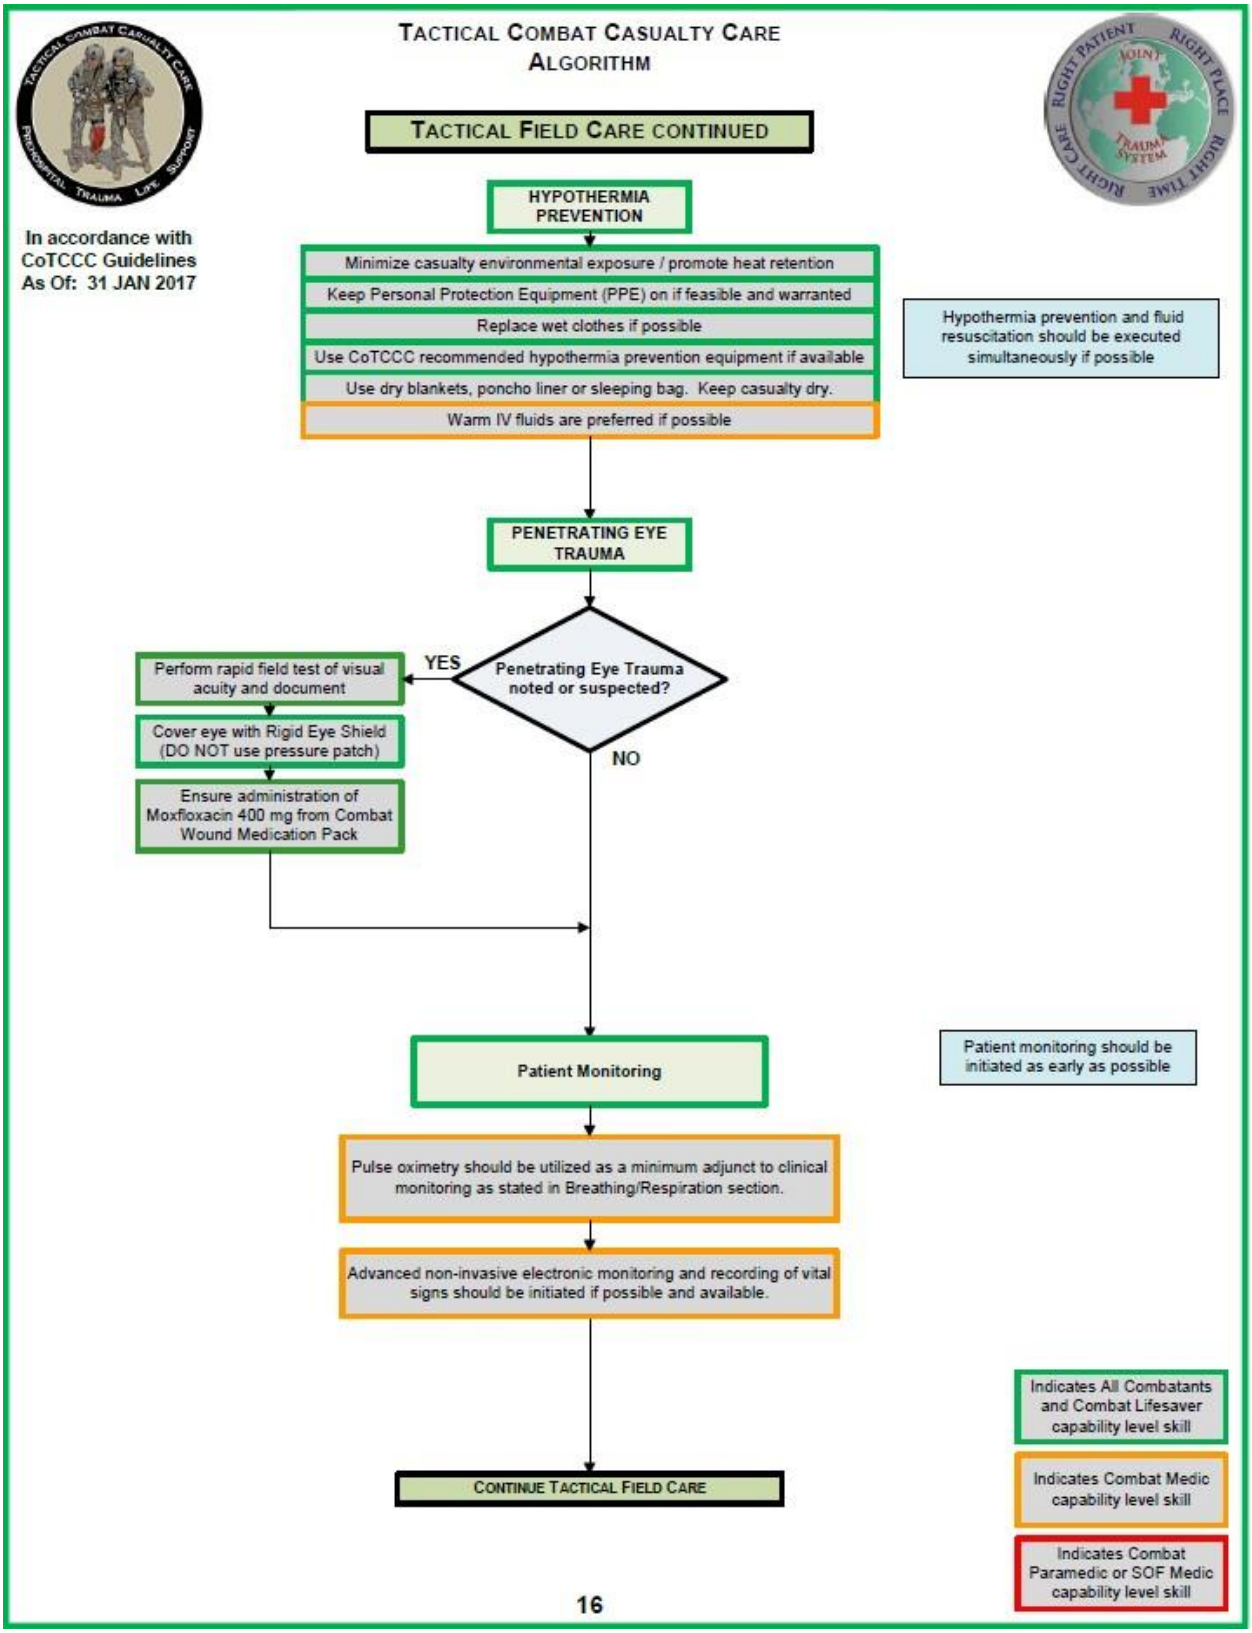
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (BLEEDING)
Bleeding Assessment
Pelvic Binder indicated?
YES
Apply a Pelvic Binder
NO
Pelvic Binder Indications- Severe blunt trauma or blast injury with one or more of the following:
-Pelvic pain
-Any major lower limb amputation/near amputation
-Physical exam suggestive of pelvic fracture
-Unconsciousness or Shock
Reassess previously applied tourniquets.
Reassess previously applied hemostatic dressings/agents
Each hemostatic works differently. If one fails to control bleeding, it may be removed and a fresh dressing of the same type or a different type applied (Xstat cannot be removed in the field)
Tourniquet not needed criteria:
-Minor lacerations w/minimal bleeding
-Surface Abrasions
-Bleeding controlled by pressure dressing
Expose wound and determine if tourniquet is needed.
NO
YES
Loosen tourniquet in <2 hours if bleeding can be controlled by other means. Leave tourniquet loosely on limb for rapid reapplication if needed. Do not remove if TQ in place >6 hours.
Leave previous tourniquet in place
Note time of tourniquet release on tourniquet and/or casualty card
Place second tourniquet 2-3 inches above wound on skin.
Control bleeding with hemostatic and/or pressure dressing.
Loosen first tourniquet once second tourniquet is effectively placed
Bleeding Controlled?
YES
Leave tourniquet in place – maximum 2 hours of tourniquet time until reassessment
NO
Before 2 hours, reassess: if not in shock, able to monitor the wound closely for bleeding, and no amputation – control bleeding with hemostatic and/or pressure dressing. Do not remove if TQ in place >6 hours.
Move original tourniquet to position next to second tourniquet directly on skin and tighten both until bleeding stopped and distal pulse not palpated
Note time of tourniquet release on tourniquet and/or casualty card
Note time of tourniquet reapplication on tourniquet and/or casualty card
If needed, control bleeding with hemostatic and/or pressure dressing.
Monitor wound closely for bleeding
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
13



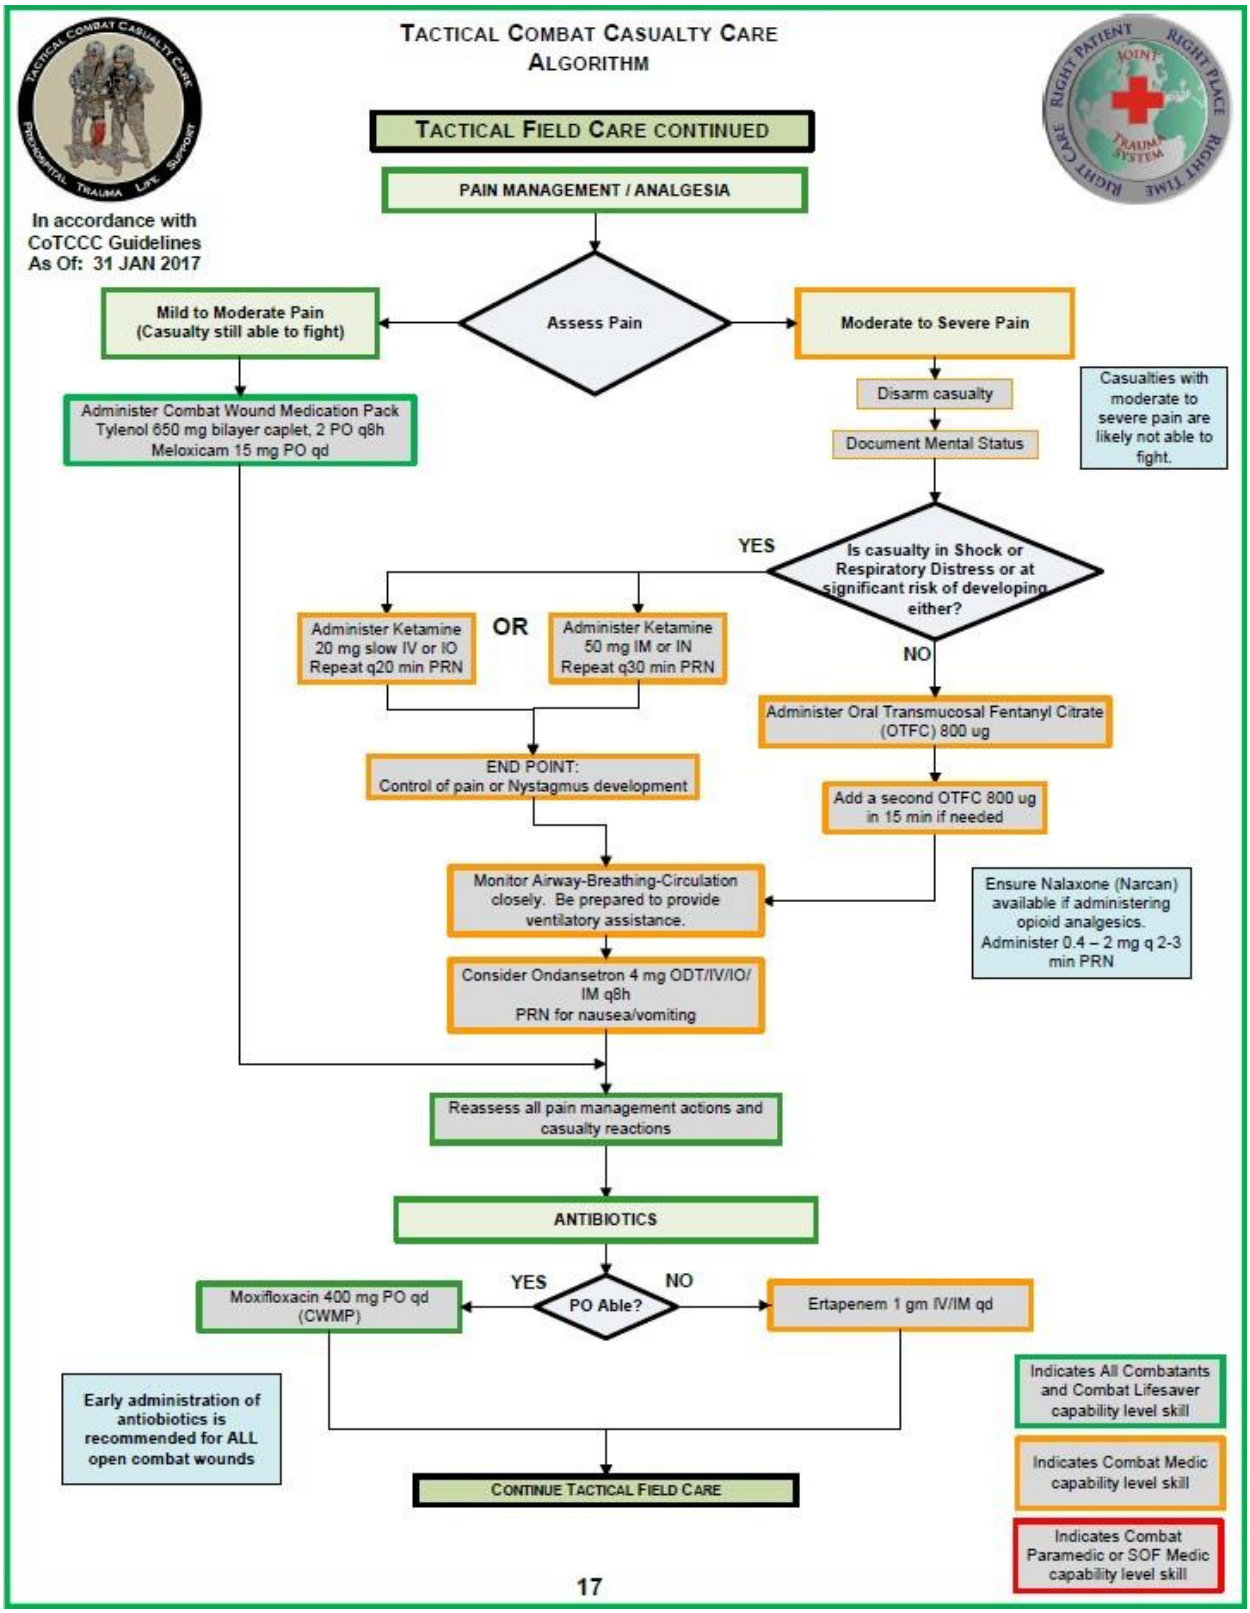
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (INTRAVENOUS ACCESS)
IV/IO Indications:
-In hemorrhagic shock or at significant risk of shock
-Casualty needs IV/IO medications
IV access indicated?
NO
YES
Initiate 18G IV or Saline Lock
If IV is not obtainable, use IO route
CIRCULATION (TRANEXAMIC ACID)
Administer 1 gm of Tranexamic Acid (TXA) in 100 ml of NS or LR IV over 10min
Administer as soon as possible after injury
Do NOT administer >3hours after injury
YES
TXA Needed?
NO
TXA Criteria:
-Presents with Hemorrhagic Shock
-One or more major amputations
-Penetrating torso trauma
-Evidence of severe bleeding
After initial fluid resuscitation, administer second dose of Tranexamic Acid (TXA) 1 gm in 100 ml of NS or LR IV over 10 min
Do NOT administer 3 hours or more after injury
Reassess frequently for presence of shock
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
14



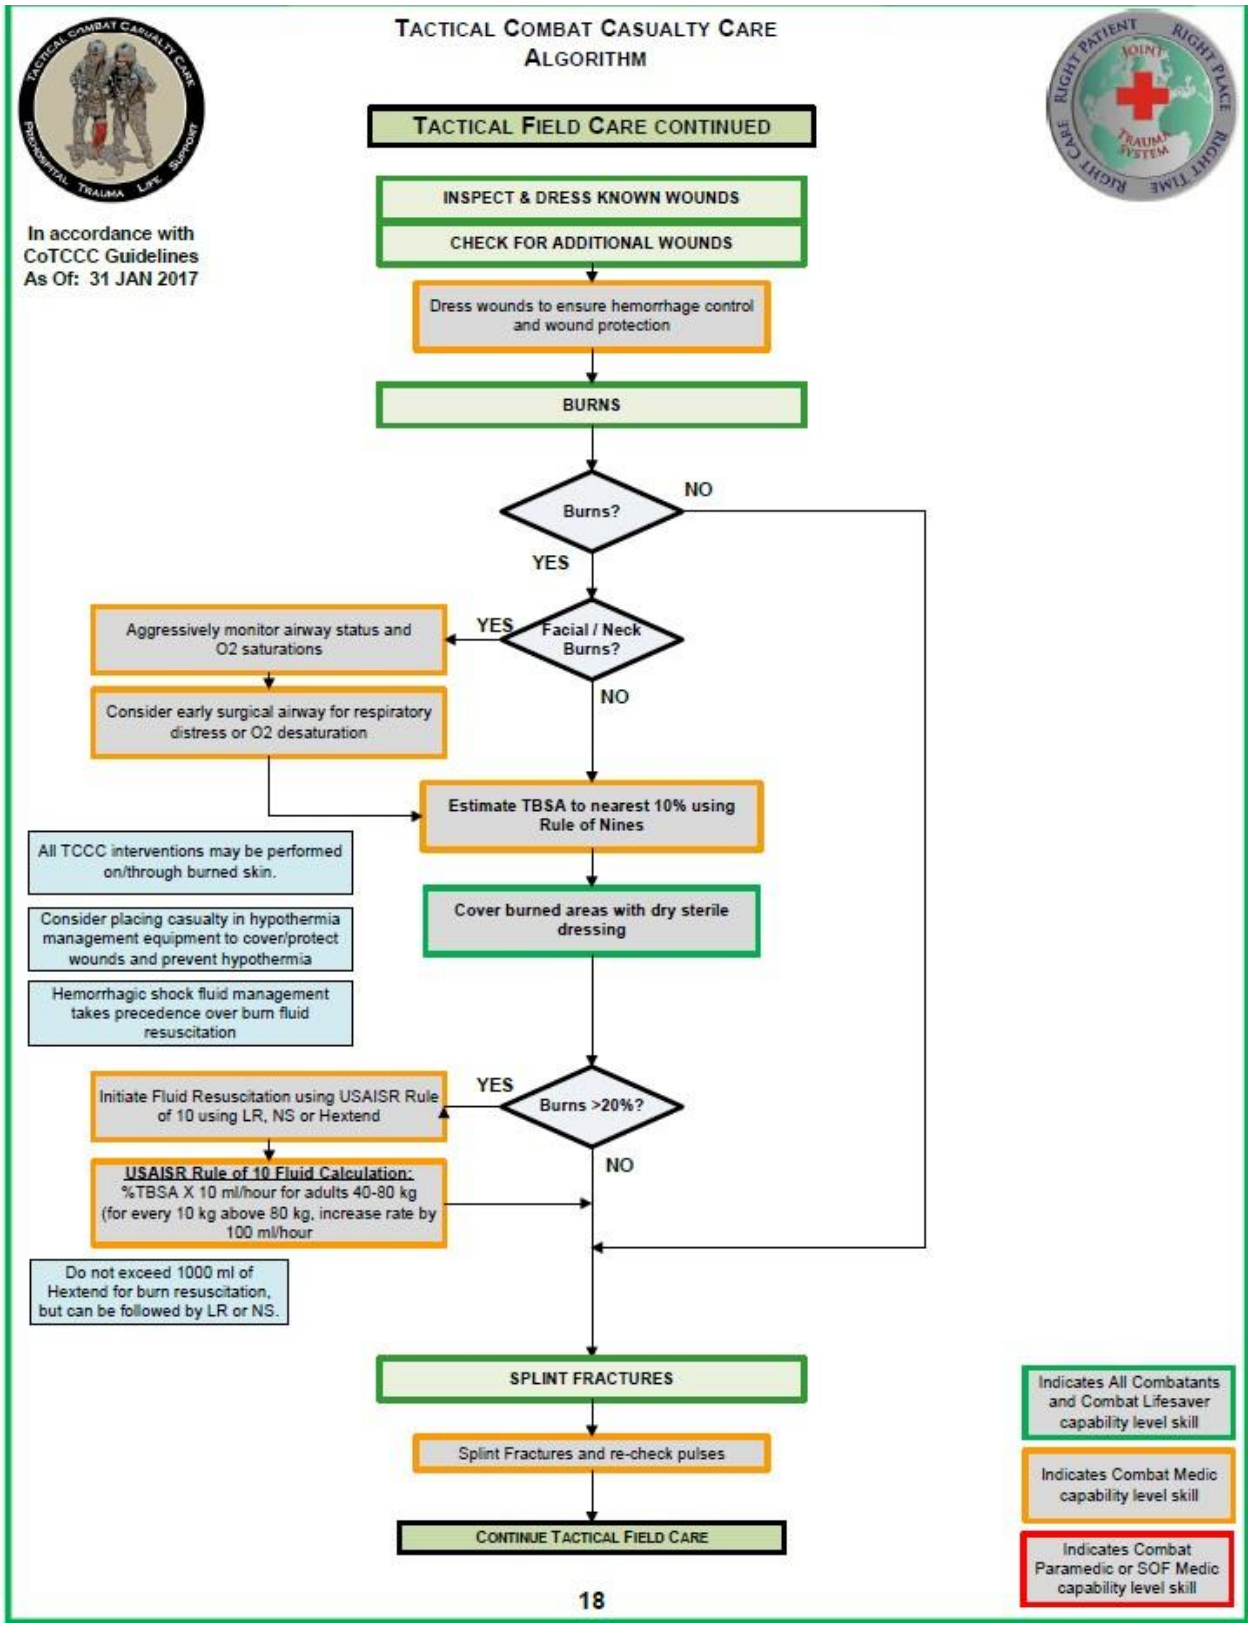
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (SHOCK / FLUID RESUSCITATION)
Assess for Shock
Shock Criteria:
-Altered Mental Status (in absence of TBI)
-Weak/Absent Radial Pulse
Hemorrhagic shock present?
NO
YES
If not in shock, NO IV fluids are immediately necessary
PO fluids permissible if casualty is conscious and can swallow
Fluid Resuscitation (in preferred order/combinations)
Blood Products Available?
YES
NO
Whole Blood Transfusion
OR, if not available
Plasma, RBCs, Platelets 1:1:1
OR, if not available
Plasma and RBCs 1:1
OR, if not available
Plasma (reconstituted, liquid, or thawed) or RBCs
Hextend 500 ml bolus
OR, if not available
Lactated Ringers 500 ml OR Plasma-Lyte A 500 ml bolus
Re-assess after each unit or 500 cc bolus administered
Continue fluid resuscitation until: Palpable radial pulse OR Improved mental status OR Systolic BP of 80-90 mmHg
If altered mental status due to suspected TBI and has weak/absent radial pulse, then resuscitate to restore normal radial pulse or Systolic BP >90mmHg
Fluid resuscitation and hypothermia prevention should be executed simultaneously if possible
After initial fluid resuscitation, administer second dose of Tranexamic Acid (TXA) 1 gm in 100 ml of NS or LR IV over 10 min Do NOT administer 3 hours or more after injury
If shock recurs, check all hemorrhage management interventions for effectiveness. Repeat fluid resuscitation.
Reassess frequently for presence of shock
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
15



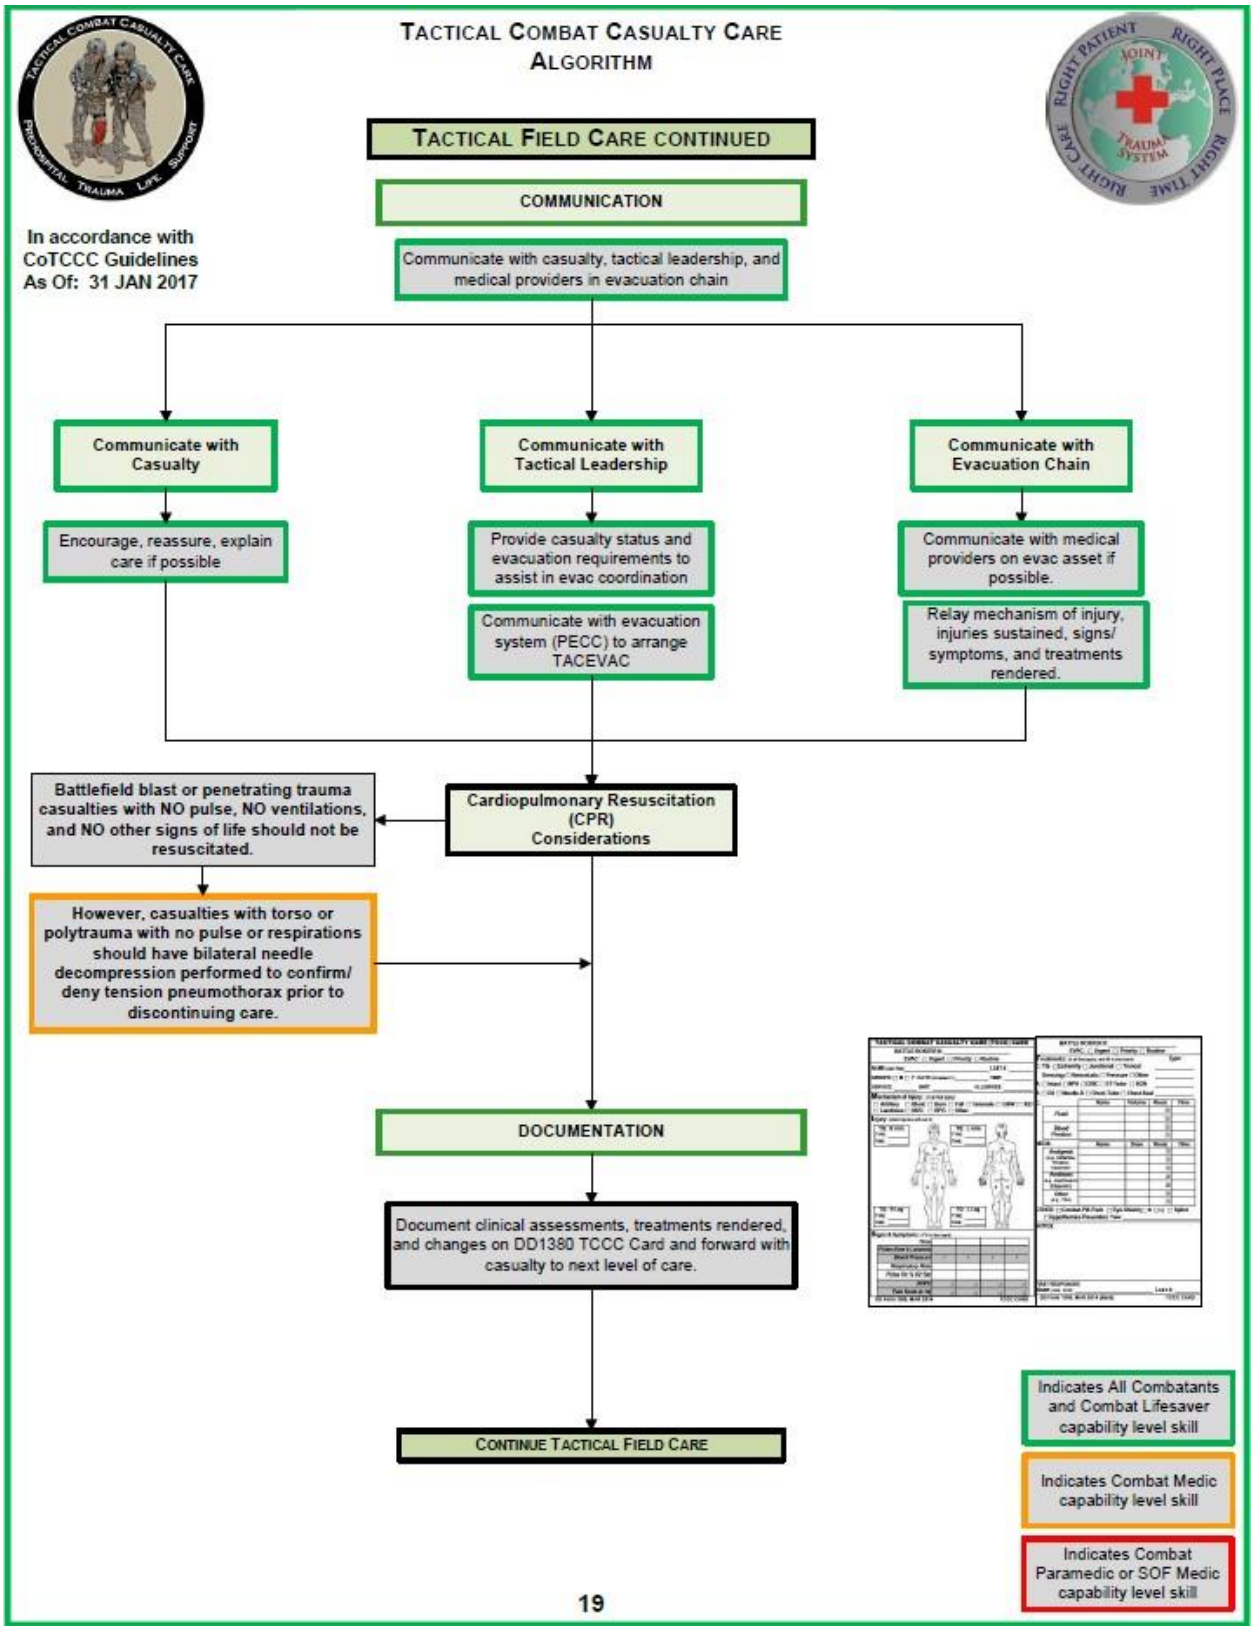
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
HYPOTHERMIA PREVENTION
Minimize casualty environmental exposure / promote heat retention
Keep Personal Protection Equipment (PPE) on if feasible and warranted
Replace wet clothes if possible
Use CoTCCC recommended hypothermia prevention equipment if available
Use dry blankets, poncho liner or sleeping bag. Keep casualty dry.
Warm IV fluids are preferred if possible
Hypothermia prevention and fluid resuscitation should be executed simultaneously if possible
PENETRATING EYE TRAUMA
Penetrating Eye Trauma noted or suspected?
YES
Perform rapid field test of visual acuity and document
Cover eye with Rigid Eye Shield (DO NOT use pressure patch)
Ensure administration of Moxfloxacin 400 mg from Combat Wound Medication Pack
NO
Patient Monitoring
Patient monitoring should be initiated as early as possible
Pulse oximetry should be utilized as a minimum adjunct to clinical monitoring as stated in Breathing/Respiration section.
Advanced non-invasive electronic monitoring and recording of vital signs should be initiated if possible and available.
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
16



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
PAIN MANAGEMENT / ANALGESIA
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
Assess Pain
Mild to Moderate Pain (Casualty still able to fight)
Moderate to Severe Pain
Administer Combat Wound Medication Pack Tylenol 650 mg bilayer caplet, 2 PO q8h Meloxicam 15 mg PO qd
Disarm casualty
Document Mental Status
Casualties with moderate to severe pain are likely not able to fight.
YES
Is casualty in Shock or Respiratory Distress or at significant risk of developing either?
NO
Administer Ketamine 20 mg slow IV or IO Repeat q20 min PRN
OR
Administer Ketamine 50 mg IM or IN Repeat q30 min PRN
Administer Oral Transmucosal Fentanyl Citrate (OTFC) 800 ug
END POINT: Control of pain or Nystagmus development
Add a second OTFC 800 ug in 15 min if needed
Monitor Airway-Breathing-Circulation closely. Be prepared to provide ventilatory assistance.
Ensure Nalaxone (Narcan) available if administering opioid analgesics. Administer 0.4 – 2 mg q 2-3 min PRN
Consider Ondansetron 4 mg ODT/IV/IO/ IM q8h PRN for nausea/vomiting
Reassess all pain management actions and casualty reactions
ANTIBIOTICS
YES
PO Able?
NO
Moxifloxacin 400 mg PO qd (CWMP)
Ertapenem 1 gm IV/IM qd
Early administration of antiobiotics is recommended for ALL open combat wounds
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
17



TACTICAL COMBAT CASUALTY CARE ALGORITHM
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
TACTICAL FIELD CARE CONTINUED
INSPECT & DRESS KNOWN WOUNDS
CHECK FOR ADDITIONAL WOUNDS
Dress wounds to ensure hemorrhage control and wound protection
BURNS
Burns?
NO
YES
Facial / Neck Burns?
YES
Aggressively monitor airway status and O2 saturations
Consider early surgical airway for respiratory distress or O2 desaturation
NO
Estimate TBSA to nearest 10% using Rule of Nines
All TCCC interventions may be performed on/through burned skin.
Consider placing casualty in hypothermia management equipment to cover/protect wounds and prevent hypothermia
Hemorrhagic shock fluid management takes precedence over burn fluid resuscitation
Cover burned areas with dry sterile dressing
Burns >20%?
YES
Initiate Fluid Resuscitation using USAISR Rule of 10 using LR, NS or Hextend
NO
USAISR Rule of 10 Fluid Calculation:
%TBSA X 10 ml/hour for adults 40-80 kg
(for every 10 kg above 80 kg, increase rate by 100 ml/hour
Do not exceed 1000 ml of Hextend for burn resuscitation, but can be followed by LR or NS.
SPLINT FRACTURES
Splint Fractures and re-check pulses
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
18



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL FIELD CARE CONTINUED
COMMUNICATION
Communicate with casualty, tactical leadership, and medical providers in evacuation chain
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
Communicate with Casualty
Encourage, reassure, explain care if possible
Communicate with Tactical Leadership
Provide casualty status and evacuation requirements to assist in evac coordination
Communicate with evacuation system (PECC) to arrange TACEVAC
Communicate with Evacuation Chain
Communicate with medical providers on evac asset if possible.
Relay mechanism of injury, injuries sustained, signs/ symptoms, and treatments rendered.
Cardiopulmonary Resuscitation (CPR) Considerations
Battlefield blast or penetrating trauma casualties with NO pulse, NO ventilations, and NO other signs of life should not be resuscitated.
However, casualties with torso or polytrauma with no pulse or respirations should have bilateral needle decompression performed to confirm/ deny tension pneumothorax prior to discontinuing care.
DOCUMENTATION
Document clinical assessments, treatments rendered, and changes on DD1380 TCCC Card and forward with casualty to next level of care.
CONTINUE TACTICAL FIELD CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill

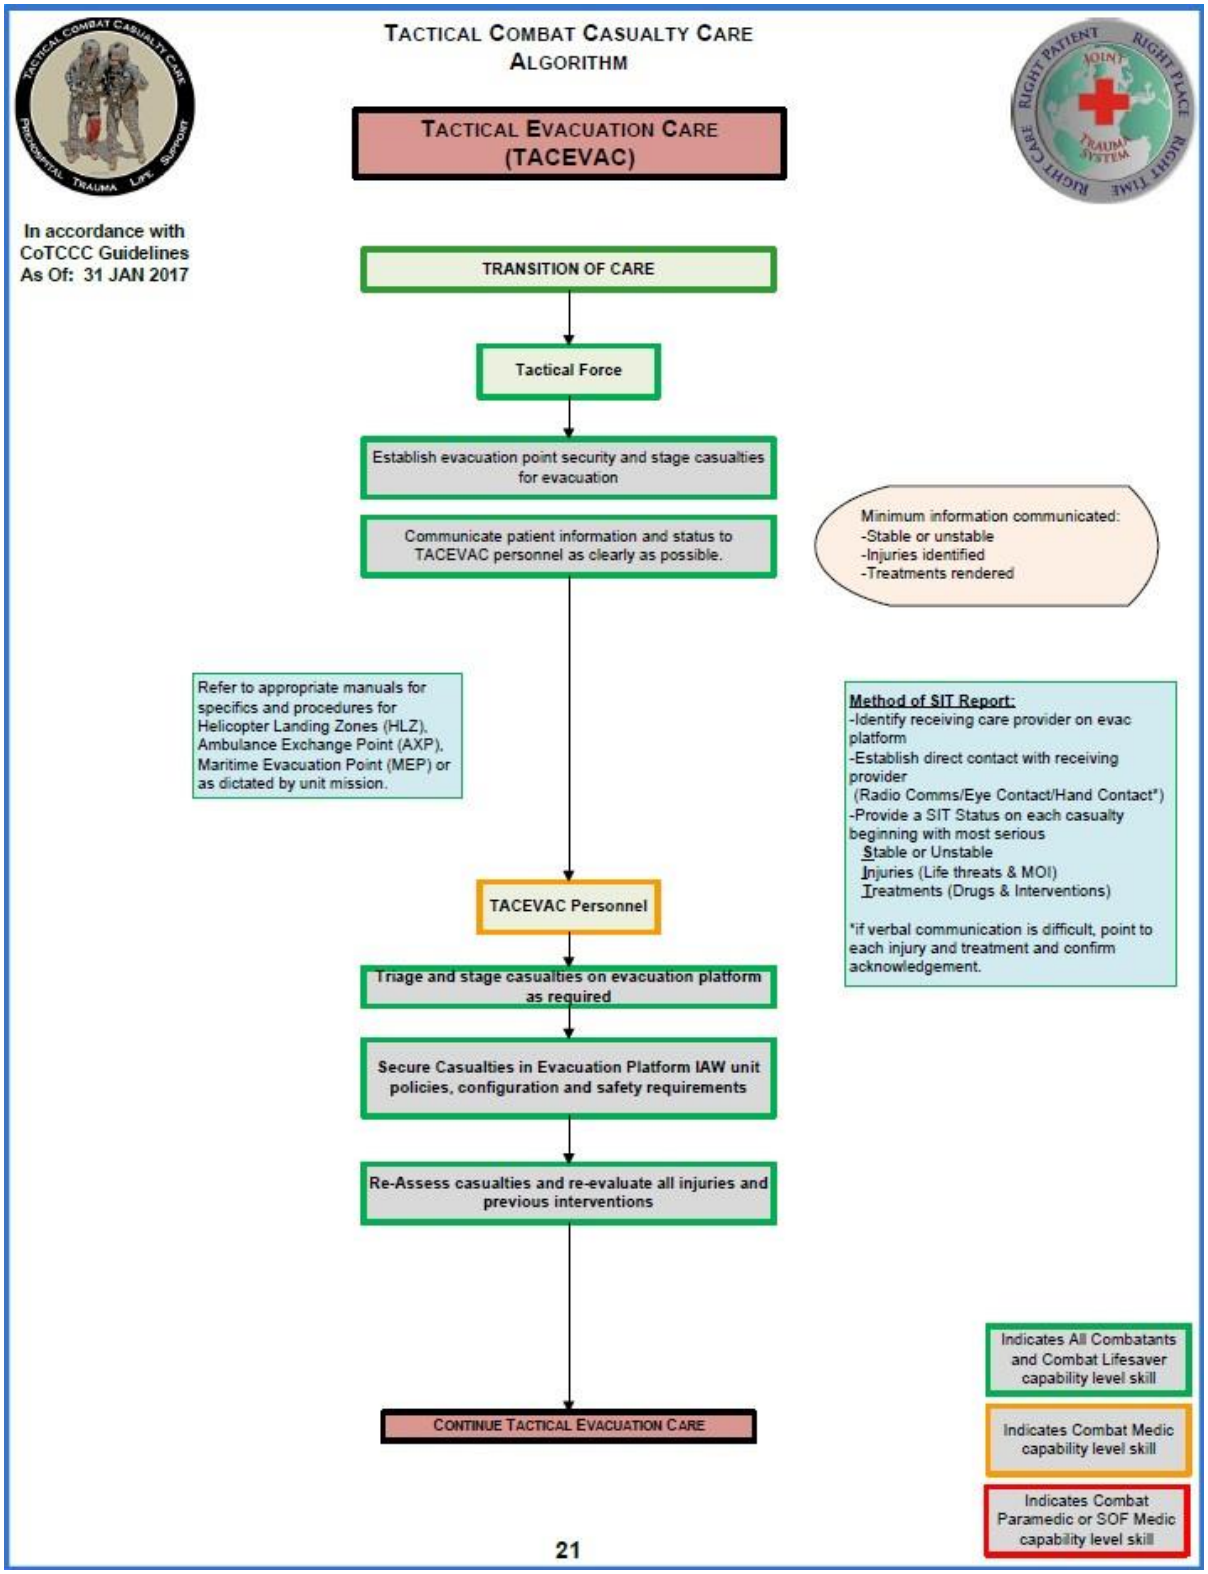
VI. TACTICAL COMBAT CASUALTY CARE (TCCC)

4. Tactical Evacuation Care Algorithm



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
TRANSITION OF CARE
Tactical Force
Establish evacuation point security and stage casualties for evacuation
Communicate patient information and status to TACEVAC personnel as clearly as possible.
Minimum information communicated:
-Stable or unstable
-Injuries identified
-Treatments rendered
Refer to appropriate manuals for specifics and procedures for Helicopter Landing Zones (HLZ), Ambulance Exchange Point (AXP), Maritime Evacuation Point (MEP) or as dictated by unit mission.
Method of SIT Report:
-Identify receiving care provider on evac platform
-Establish direct contact with receiving provider
(Radio Comms/Eye Contact/Hand Contact*)
-Provide a SIT Status on each casualty beginning with most serious
Stable or Unstable
Injuries (Life threats & MOI)
Treatments (Drugs & Interventions)
*if verbal communication is difficult, point to each injury and treatment and confirm acknowledgement.
TACEVAC Personnel
Triage and stage casualties on evacuation platform as required
Secure Casualties in Evacuation Platform IAW unit policies, configuration and safety requirements
Re-Assess casualties and re-evaluate all injuries and previous interventions
CONTINUE TACTICAL EVACUATION CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
21

RESPIRATION / BREATHING
Assess Respiration / Breathing
Progressive Respiratory Distress and Known or Suspected Torso Trauma?
NO
YES
Suspect/Consider Tension Pneumothorax
Needle Decompress Chest at Primary or Alternate Site on injured side. Repeat as necessary.
Open/Sucking Chest Wound?
NO
YES
Apply Vented Chest Seal to all open/ sucking chest wounds
Vented chest seals are preferred over non-vented.
Initiate Pulse Oximetry Monitoring if not previously done
MONITOR FOR TENSION PNEUMOTHORAX
Tension Pneumothorax Suspected?
YES
Burp or remove chest seal if applied. Repeat as necessary.
Needle Decompress Chest at Primary or Alternate Site if indicated. Repeat as necessary.
NO
TENSION PNEUMOTHORAX INDICATORS:
Increasing Hypoxia
Respiratory Distress
Hypotension
Administer Oxygen when possible as indicated:
-Low oxygen saturation by pulsoximetry
-Injuries associated with impaired oxygenation
-Unconscious casualty
-Casualty in shock
-Casualty at altitude
-Known or suspected smoke inhalation
If moderate or severe TBI is suspected, provide supplemental O2 if available to maintain SpO2>90%
Consider chest tube insertion if no improvement and/or long transport anticipated
CONTINUE TACTICAL EVACUATION CARE
Decompression Needle

TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (BLEEDING)
Bleeding Assessment
Pelvic Binder indicated?
YES
Apply a Pelvic Binder
NO
Pelvic Binder Indications- Severe blunt trauma or blast injury with one or more of the following:
-Pelvic pain
-Any major lower limb amputation/near amputation
-Physical exam suggestive of pelvic fracture
-Unconsciousness or Shock
Reassess previously applied tourniquets.
Each hemostatic works differently. If one fails to control bleeding, it may be removed and a fresh dressing of the same type or a different type applied (Xstat cannot be removed in the field)
Reassess previously applied hemostatic dressings/agents
Tourniquet not needed criteria:
-Minor lacerations w/minimal bleeding
-Surface Abrasions
-Bleeding controlled by pressure dressing
Expose wound and determine if tourniquet is needed.
NO
Loosen tourniquet in <2 hours if bleeding can be controlled by other means. Leave tourniquet loosely on limb for rapid reapplication if needed. Do not remove if TQ in place >6 hours.
YES
Leave previous tourniquet in place
Note time of tourniquet release on tourniquet and/or casualty card
Place second tourniquet 2-3 inches above wound on skin.
Control bleeding with hemostatic and/or pressure dressing.
Loosen first tourniquet once second tourniquet is effectively placed
Leave tourniquet in place – maximum 2 hours of tourniquet time until reassessment
YES
Bleeding Controlled?
NO
Before 2 hours, reassess: if not in shock, able to monitor the wound closely for bleeding, and no amputation – control bleeding with hemostatic and/or pressure dressing. Do not remove if TQ in place >6 hours.
Move original tourniquet to position next to second tourniquet directly on skin and tighten both until bleeding stopped and distal pulse not palpated
Note time of tourniquet release on tourniquet and/or casualty card
Note time of tourniquet reapplication on tourniquet and/or casualty card
If needed, control bleeding with hemostatic and/or pressure dressing.
Monitor wounds closely for bleeding

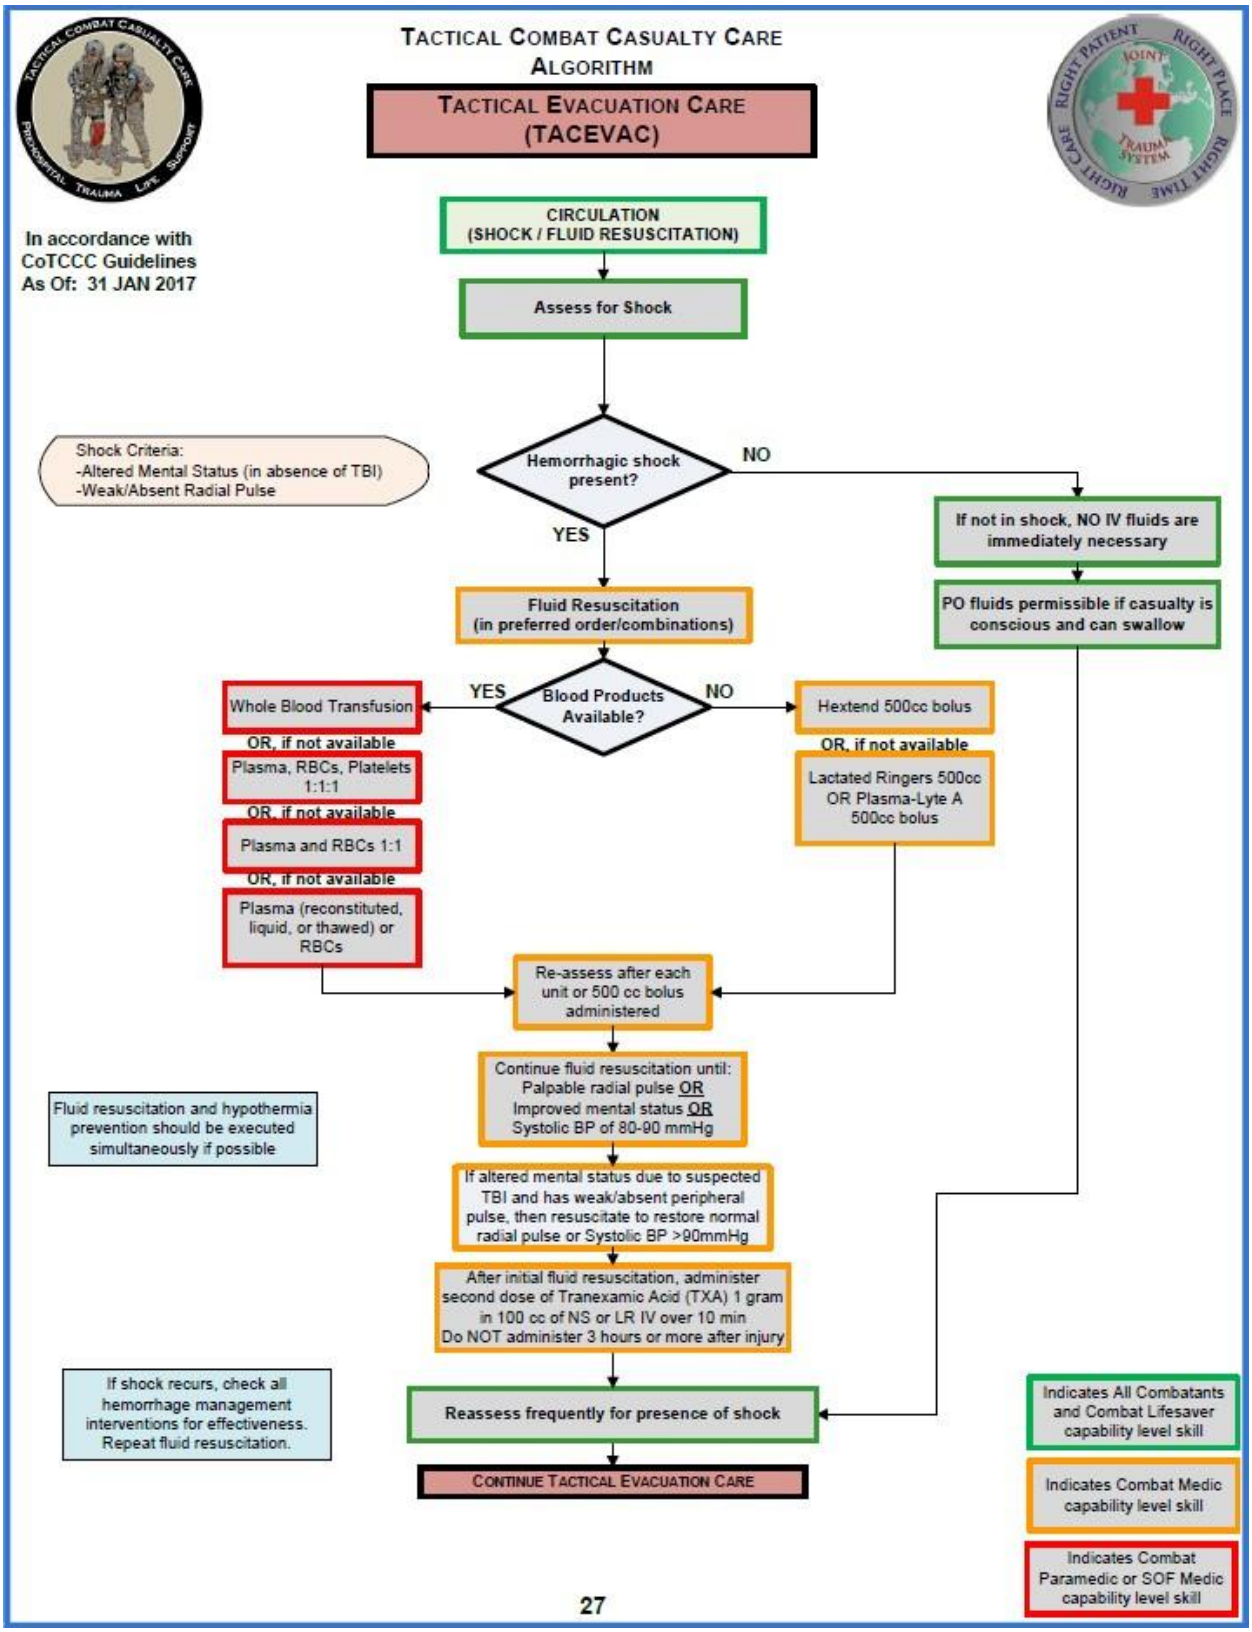
TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (INTRAVENOUS ACCESS)
IV/IO Indications:
-In hemorrhagic shock or at significant risk of shock
-Casualty needs IV/IO medications
IV access indicated?
NO
YES
Initiate 18G IV or Saline Lock
If IV is not obtainable, use IO route
CIRCULATION (TRANEXAMIC ACID)
Administer 1 gm of Tranexamic Acid (TXA) in 100 ml of NS or LR IV over 10min
Administer as soon as possible after injury
Do NOT administer >3hours after injury
YES
TXA Needed?
NO
TXA Criteria:
-Presents with Hemorrhagic Shock
-One or more major amputations
-Penetrating torso trauma
-Evidence of severe bleeding
After initial fluid resuscitation, administer second dose of Tranexamic Acid (TXA) 1 gm in 100 ml of NS or LR IV over 10 min
Do NOT administer 3 hours or more after injury
Reassess frequently for presence of shock
CONTINUE TACTICAL EVACUATION CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
26



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
CIRCULATION (SHOCK / FLUID RESUSCITATION)
Assess for Shock
Shock Criteria:
-Altered Mental Status (in absence of TBI)
-Weak/Absent Radial Pulse
Hemorrhagic shock present?
NO
YES
If not in shock, NO IV fluids are immediately necessary
PO fluids permissible if casualty is conscious and can swallow
Fluid Resuscitation (in preferred order/combinations)
Blood Products Available?
YES
NO
Whole Blood Transfusion
OR, if not available
Plasma, RBCs, Platelets 1:1:1
OR, if not available
Plasma and RBCs 1:1
OR, if not available
Plasma (reconstituted, liquid, or thawed) or RBCs
Hextend 500cc bolus
OR, if not available
Lactated Ringers 500cc OR Plasma-Lyte A 500cc bolus
Re-assess after each unit or 500 cc bolus administered
Continue fluid resuscitation until: Palpable radial pulse OR Improved mental status OR Systolic BP of 80-90 mmHg
Fluid resuscitation and hypothermia prevention should be executed simultaneously if possible
If altered mental status due to suspected TBI and has weak/absent peripheral pulse, then resuscitate to restore normal radial pulse or Systolic BP >90mmHg
After initial fluid resuscitation, administer second dose of Tranexamic Acid (TXA) 1 gram in 100 cc of NS or LR IV over 10 min Do NOT administer 3 hours or more after injury
If shock recurs, check all hemorrhage management interventions for effectiveness. Repeat fluid resuscitation.
Reassess frequently for presence of shock
CONTINUE TACTICAL EVACUATION CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill

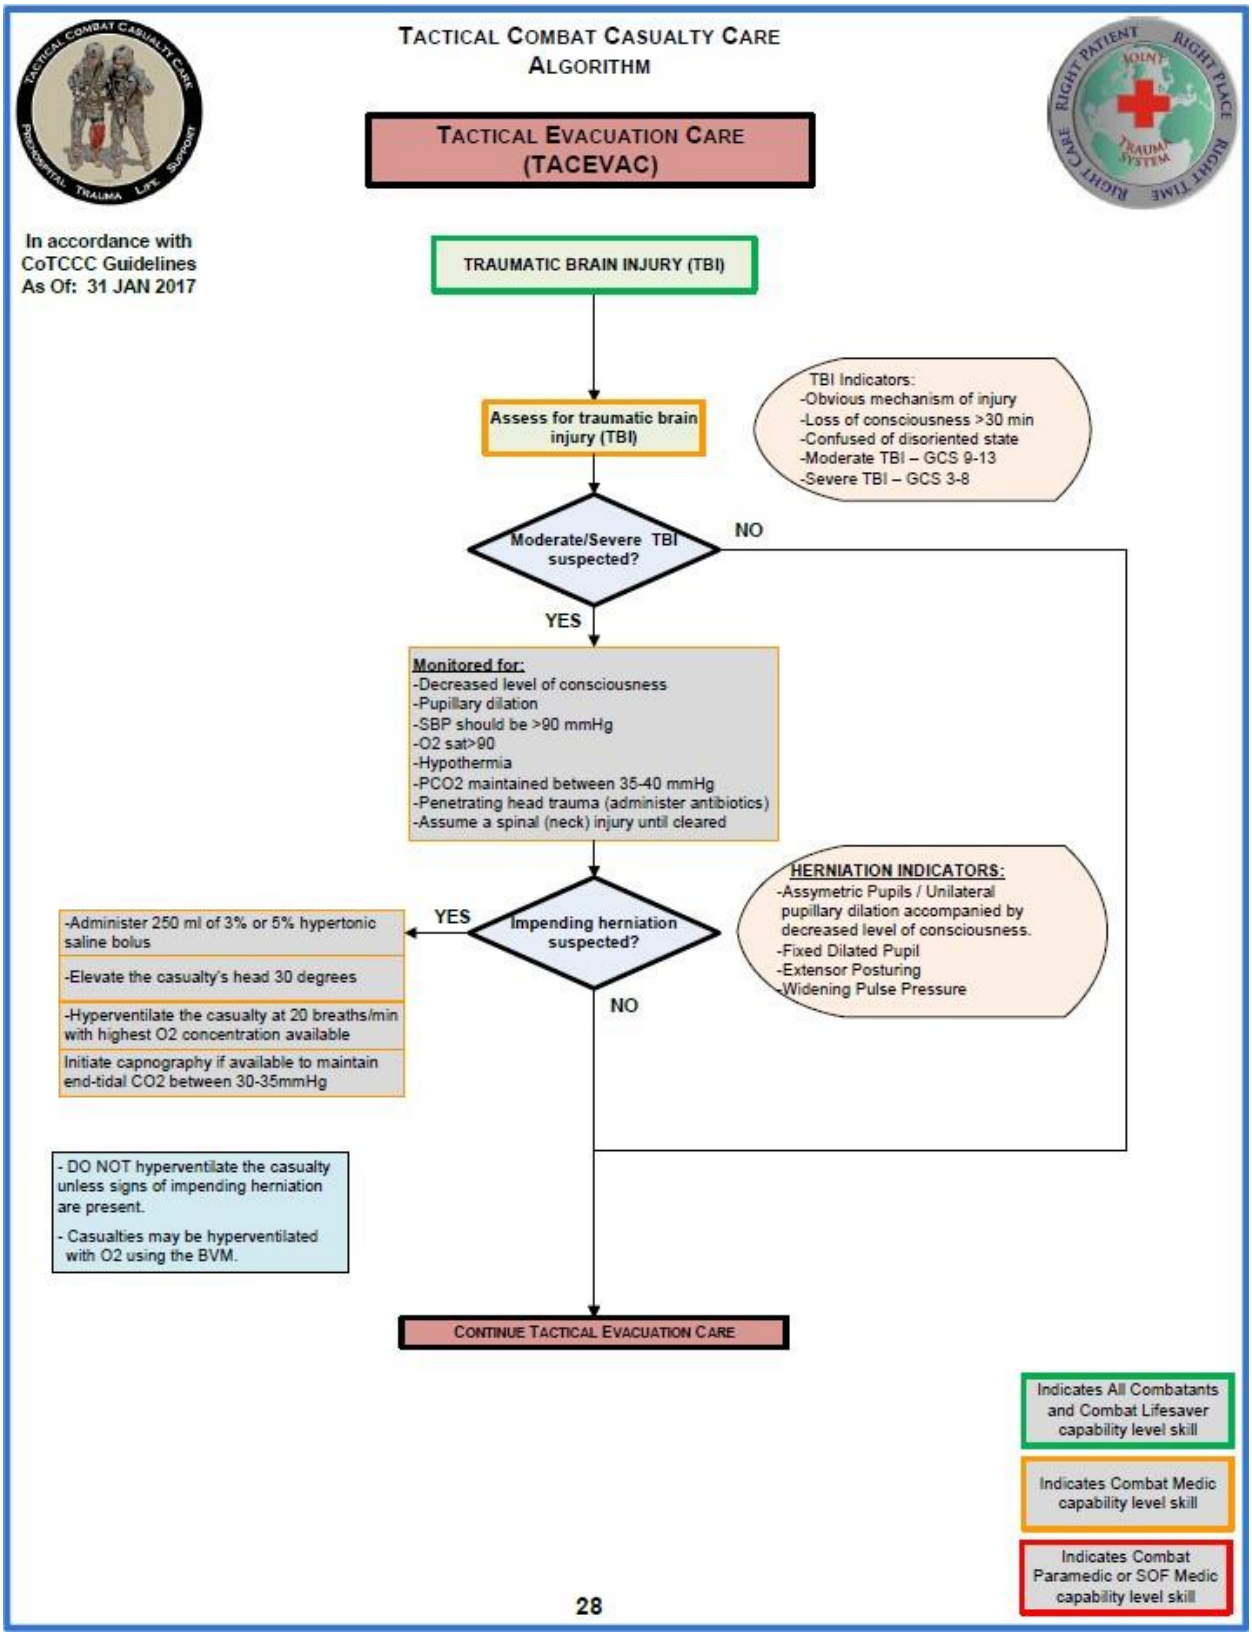
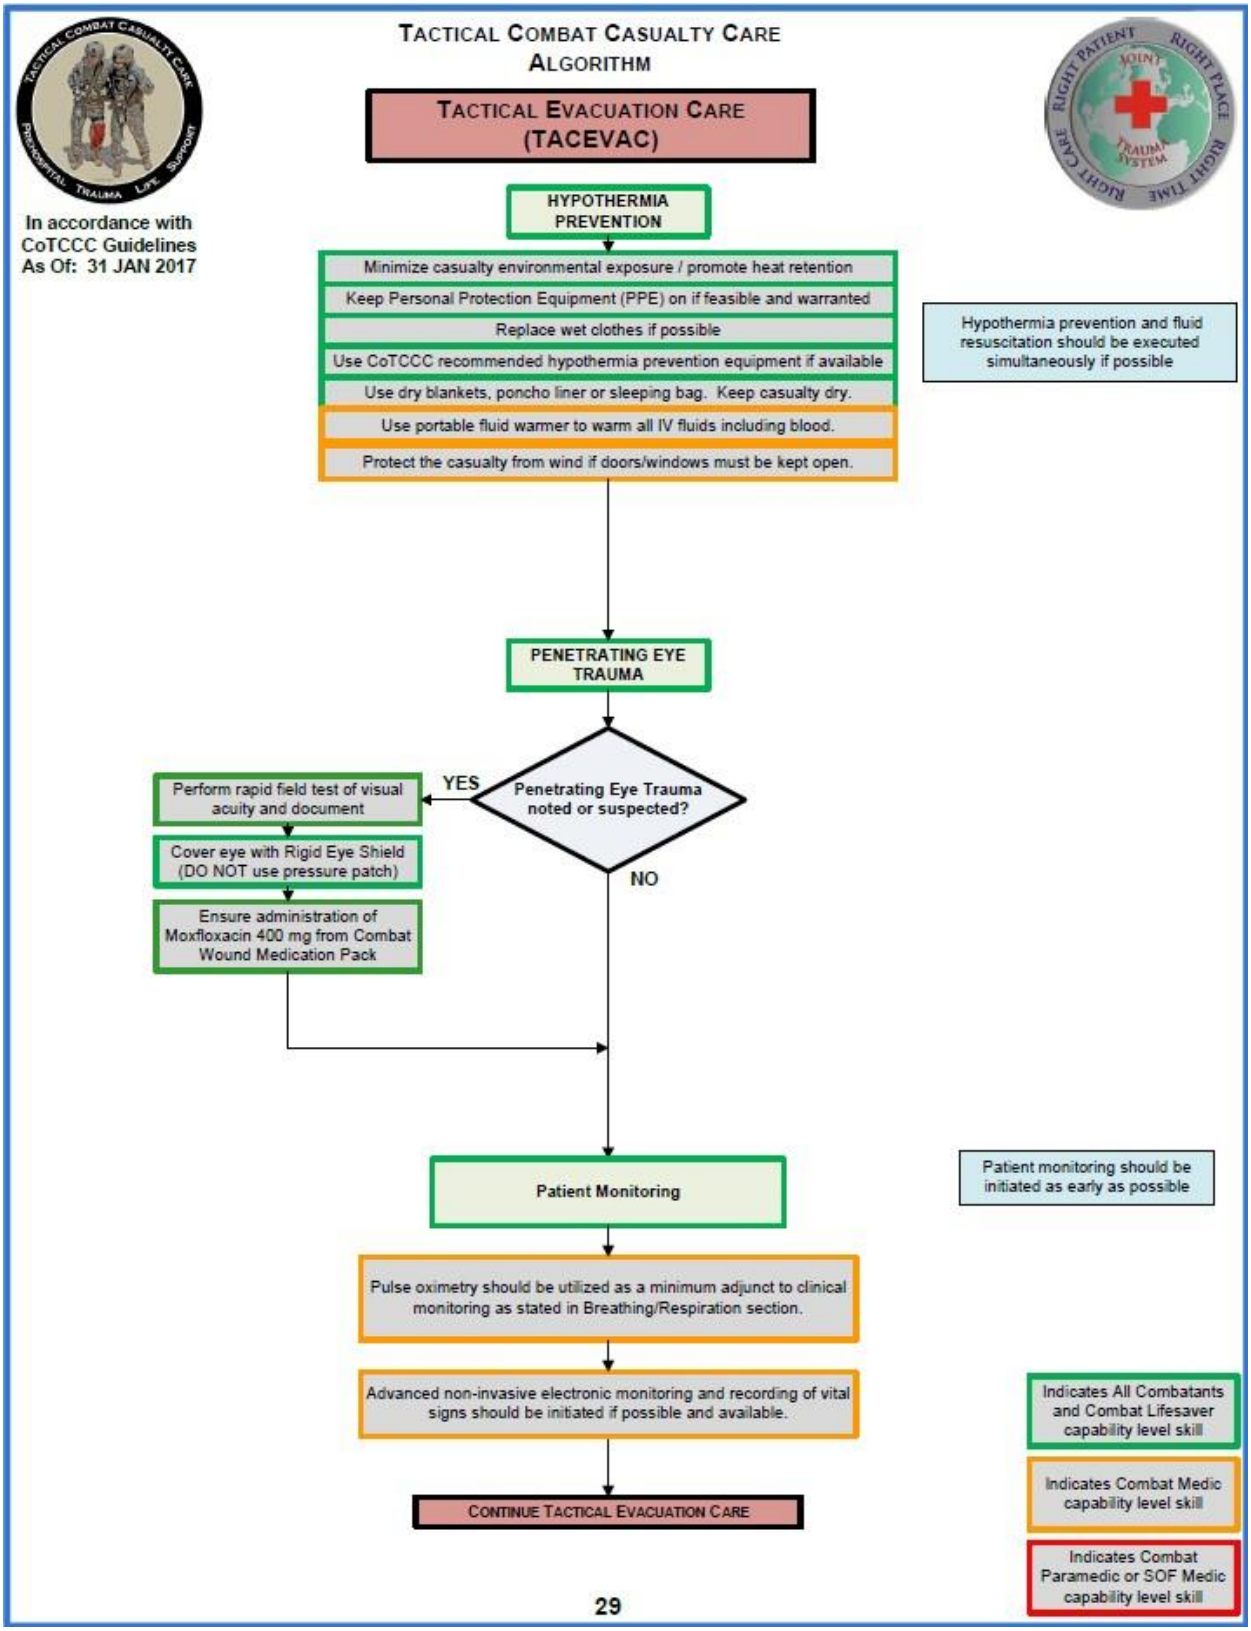
27



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
TRAUMATIC BRAIN INJURY (TBI)
Assess for traumatic brain injury (TBI)
TBI Indicators:
-Obvious mechanism of injury
-Loss of consciousness >30 min
-Confused of disoriented state
-Moderate TBI – GCS 9-13
-Severe TBI – GCS 3-8
Moderate/Severe TBI suspected?
NO
YES
Monitored for:
-Decreased level of consciousness
-Pupillary dilation
-SBP should be >90 mmHg
-O2 sat>90
-Hypothermia
-PCO2 maintained between 35-40 mmHg
-Penetrating head trauma (administer antibiotics)
-Assume a spinal (neck) injury until cleared
Impending herniation suspected?
YES
NO
HERNIATION INDICATORS:
-Assymetric Pupils / Unilateral pupillary dilation accompanied by decreased level of consciousness.
-Fixed Dilated Pupil
-Extensor Posturing
-Widening Pulse Pressure
-Administer 250 ml of 3% or 5% hypertonic saline bolus
-Elevate the casualty's head 30 degrees
-Hyperventilate the casualty at 20 breaths/min with highest O2 concentration available
Initiate capnography if available to maintain end-tidal CO2 between 30-35mmHg
- DO NOT hyperventilate the casualty unless signs of impending herniation are present.
- Casualties may be hyperventilated with O2 using the BVM.
CONTINUE TACTICAL EVACUATION CARE
Indicates All Combatants and Combat Lifesaver capability level skill
Indicates Combat Medic capability level skill
Indicates Combat Paramedic or SOF Medic capability level skill
28



TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
HYPOTHERMIA PREVENTION
Minimize casualty environmental exposure / promote heat retention
Keep Personal Protection Equipment (PPE) on if feasible and warranted
Replace wet clothes if possible
Use CoTCCC recommended hypothermia prevention equipment if available
Use dry blankets, poncho liner or sleeping bag. Keep casualty dry.
Use portable fluid warmer to warm all IV fluids including blood.
Protect the casualty from wind if doors/windows must be kept open.
Hypothermia prevention and fluid resuscitation should be executed simultaneously if possible
PENETRATING EYE TRAUMA
Penetrating Eye Trauma noted or suspected?
YES
Perform rapid field test of visual acuity and document
Cover eye with Rigid Eye Shield (DO NOT use pressure patch)
Ensure administration of Moxfloxacin 400 mg from Combat Wound Medication Pack
NO
Patient Monitoring
Patient monitoring should be initiated as early as possible
Pulse oximetry should be utilized as a minimum adjunct to clinical monitoring as stated in Breathing/Respiration section.
Advanced non-invasive electronic monitoring and recording of vital signs should be initiated if possible and available.

TACTICAL COMBAT CASUALTY CARE ALGORITHM
TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
PAIN MANAGEMENT / ANALGESIA
Assess Pain
Mild to Moderate Pain (Casualty still able to fight)
Moderate to Severe Pain
Administer Combat Wound Medications Pack Tylenol 650 mg bilayer caplet, 2 PO q8h Meloxicam 15 mg PO qd
Disarm casualty
Document Mental Status
YES
Is casualty in Shock or Respiratory Distress or at significant risk of developing either?
NO
Administer Ketamine 20 mg slow IV or IO Repeat q20 min PRN
OR
Administer Ketamine 50 mg IM or IN Repeat q30 min PRN
Administer Oral Transmucosal Fentanyl Citrate (OTFC) 800 ug
END POINT: Control of pain or Nystagmus development
Add a second OTFC 800 ug in 15 min if needed
Monitor Airway-Breathing-Circulation closely. Be prepared to provide ventilatory assistance.
Ensure Nalaxone (Narcan) available if administering opioid analgesics. Administer 0.4 – 2 mg q 2-3 min PRN
Consider Ondansetron 4 mg ODT/IV/IO/ IM q8h PRN for nausea/vomiting
Reassess all pain management actions and casualty reactions
ANTIBIOTICS
YES
PO Able?
NO
Moxifloxacin 400 mg PO qd (CWMP)
Ertapenem 1 gm IV/IM qd
Early administration of antiobiotics is recommended for ALL open combat wounds
CONTINUE TACTICAL EVACUATION CARE
Indicates All Combatants and Combat Lifesaver capability level skill

TACTICAL EVACUATION CARE (TACEVAC)
In accordance with CoTCCC Guidelines As Of: 31 JAN 2017
INSPECT & DRESS KNOWN WOUNDS
CHECK FOR ADDITIONAL WOUNDS
Dress wounds to ensure hemorrhage control and wound protection
BURNS
Burns?
NO
YES
Facial / Neck Burns?
YES
Aggressively monitor airway status and O2 saturations
Consider early surgical airway for respiratory distress or O2 desaturation
NO
Estimate TBSA to nearest 10% using Rule of Nines
All TCCC interventions may be performed on/through burned skin.
Consider placing casualty in hypothermia management equipment to cover/protect wounds and prevent hypothermia
Hemorrhagic shock fluid management takes precedence over burn fluid resuscitation
Cover burned areas with dry sterile dressing
Burns >20%?
YES
Initiate Fluid Resuscitation using USAISR Rule of 10 using LR, NS or Hextend
NO
USAISR Rule of 10 Fluid Calculation:
%TBSA X 10 ml/hour for adults 40-80 kg
(for every 10 kg above 80 kg, increase rate by 100 ml/hour
Do not exceed 1000 ml of Hextend for burn resuscitation, but can be followed by LR or NS.
Extra emphasis should be placed on hypothermia prevention and IV warming for burn patients.
SPLINT FRACTURES
Splint Fractures and re-check pulses
CONTINUE TACTICAL EVACUATION CARE

TACTICAL EVACUATION CARE (TACEVAC)

COMMUNICATION

Communicate with casualty and medical providers in evacuation chain

- **Communicate with Casualty**
  - Encourage, reassure, explain care if possible
- **Communicate with Receiving Medical Facility**
  - Communicate with medical providers on evac asset if possible.
  - Relay mechanism of injury, injuries sustained, signs/ symptoms, and treatments rendered.

Cardiopulmonary Resuscitation (CPR) Considerations

CPR may be attempted in TACEVAC if casualty does not have obviously fatal wounds and quickly arriving at a surgical capability. CPR should not be attempted if compromising the mission or denying lifesaving treatment to other casualties.

Casualties with torso or polytrauma with no pulse or respirations should have bilateral needle decompression performed to confirm/deny tension pneumothorax prior to discontinuing care.

DOCUMENTATION

Document clinical assessments, treatments rendered, and changes on DD1380 TCCC Card and forward with casualty to next level of care.

NEXT LEVEL CARE

VI. TACTICAL COMBAT CASUALTY CARE (TCCC)

5. Blood/Fresh Frozen Plasma(FFP) Administration and Protocol

INDICATIONS: If the patient is in shock, especially in the presence of known or suspected non-compressible hemorrhage, then resuscitate with 2 units of plasma followed by PRBCs in a 1:1 ratio. If blood components are not available AND you are trained and comfortable with the procedure, collect and transfuse fresh whole blood. Resuscitate and attempt to maintain a palpable radial pulse or clinical improvement. If BP monitoring is available, maintain target systolic BP of 80-90mmHg (at least 90mmHg in the presence of TBI).

OVERVIEW:

1. Whole blood (WB) is blood that has not been modified except for the addition of an anticoagulant. WB provides the equivalent of Fresh Frozen Plasma (FFP), RBCs and Platelets (PLTSs) in a 1:1:1 ratio. FWB will have a shelf-life of 24 hours and should be transfused immediately or stored at 33-43 degrees F (1-6 degrees C) within 8 hours after collection, unless otherwise directed by medical staff due to insufficient or no red blood cell (RBC) or plasma product inventory. It should be tested with rapid test kits to decrease the risk of infectious disease transmission. Identify a blood donor who is ABO identical with the intended recipient.
2. WB is sometimes referred to fresh whole blood (FWB) if it has been recently collected. However, there is no time standard as to when it is no longer considered to be fresh. It is also referred to as warm fresh whole blood (WFWB) when it is still warm following collection. WB is separated into different components.

*** Any separated component, including RBCs or Packed RBCs (PRBCs), is considered a blood component and therefore **CANNOT** be correctly referred to as blood. Blood refers to WFWB, FWB, and WB.

3. The following are in use depending on theater of operations:
   a. Fresh frozen plasma (FFP)
   b. Packed red blood cells (PRBCs)
   c. Warm fresh whole blood (WFWB)
   d. Fresh whole blood (FWB)
   e. Whole blood (WB)
4. Prior to initiation of transfusion, the following will be checked:
   a. Vital signs (T, P, R, BP). Measure, evaluate and record baseline vital signs. Every effort should be made to monitor temperature as **an increase in temperature may be the first indicator of a transfusion reaction**.
   b. Casualty blood type should be confirmed.
      i. In an emergency, establish ABO/Rh of recipients and donors via local testing or previous testing.
      ii. EldonCard® tests should ONLY be used to confirm previous results obtained using the ABO/Rh test tube method.

Identification tags for ABO/Rh verification should be utilized as a last resort only. Accurate identification and verification of the donor's blood and the intended recipient may be the single most important step in ensuring transfusion safety.

   c. Active warming loss prevention should be used to prevent casualty hypothermia.

Transfusions

1. Ideally blood products should be warmed to approximately 98.6 °F (37 °C) prior to transfusion. Do not exceed 102 °F (39 °C). This may cause an inflammatory reaction and lyse some of the red cells.

Do not use warmers directly against the fluid bag because of the risk of hemolysis or damage to the blood or blood product. Blood or blood components should not be warmed in a microwave, unless it is specifically designed for that purpose.

2. Blood/blood components may be infused using a pressure infuser that encases the entire blood collection bag. Do not use a BP cuff for infusion as they deliver uneven pressure. Do not exceed 300mmHg with the pressure infusion device.

3. The largest bore IV catheter should be used. An IO device may be used. Ensure that a strong flush is done and good flow is obtained prior to using an IO infusion.

4. When performing any administration of blood or blood components the patient should be continuously monitored for signs and symptoms of an immunologic blood transfusion reaction. The first 10-15 minutes of any transfusion are the most critical.
   a. **Anaphylactic Reaction**
      i. Shock
      ii. Hypotension
      iii. Angioedema (red, swollen face)
      iv. Respiratory distress
   b. **Acute Hemolytic Transfusion Reaction**
      i. Acute Hemolytic Reaction usually has onset within 1 hour
      ii. Evidence of disseminated intravascular coagulopathy (DIC) – oozing from blood draw, IV sites.
      iii. Flushing, especially in the face
      iv. Fever and increase in core temp of more than 2 degrees F (1 degree C)
      v. Shaking, chills (rigor)
      vi. Flank pain or the acute onset of pain in the chest (retrosternal), abdomen and thighs
      vii. Wheezing, dyspnea
      viii. Anxiety, feeling of impending doom
      ix. Nausea and vomiting
      x. Hypotension
      xi. Pain, inflammation, and/or warmth at the infusion site
      xii. Red or Brown Urine (hemoglobinuria)-The onset of red urine during or shortly after a blood transfusion may represent hematuria (indicating bleeding in the lower urinary tract (tube #1 below) or hemoglobinuria (indicating an acute hemolytic reaction, tube #2 below). If freshly collected urine from a patient with hematuria is centrifuged, red blood cells settle at the bottom of the tube, leaving clear yellow urine supernatant (see tube #3 below). If the red color is due to hemoglobinuria, the urine sample remains red after centrifugation (see tube #4 below).

c. **Febrile Non Hemolytic Reactions**
   i. Fever not as severe as with an acute hemolytic reaction
   ii. Chills
   iii. Dyspnea
d. **Urticarial Reactions** - Urticaria
e. **Other transfusion related signs and symptoms**
   i. Flushing (especially in the face), urticaria, or edema
   ii. Increased pulse or respiratory rate
   iii. Nausea, vomiting or diarrhea
   iv. Pain and/or edema at the infusion site
   v. Headache
   vi. Feeling of impending doom
f. **Citrate Toxicity**
   i. Mild
      (a) Perioral and periorbital paresthesia
      (b) Metallic taste in the mouth
      (c) "Tingling" sensation around the mouth or in the extremities
   ii. Severe
      (a) Carpopedal spasms
      (b) Twitching
      (c) Chills
      (d) Stomach cramps
      (e) Pressure in the chest
      (f) Hypotension and possible cardiac arrhythmia
      (g) Nausea and/or vomiting
      (h) Tetany
      (i) Laryngeal spasm
      (j) Seizures
      (k) Bradycardia
   iii. Treatment
      (a) **Mild Toxicity** - Slow or stop transfusion until symptoms subside. Ensure proper mixture and concentration of citrate
      (b) **Severe Toxicity** - 10ml of a 10% solution of Calcium Gluconate SLOW IV push.

Do not rapidly infuse Calcium nor give more than one dose without the ability to monitor electrolytes. This may lead to cardiac arrhythmias.

5. Treatment of Immunologic Blood Transfusions Reactions. The first step in treating ALL transfusion related issues is to **STOP** the transfusion and save all of the blood products and equipment used for administration and typing for follow-up testing.

a. **Anaphylactic Reactions**
   i. Epinephrine 0.5ml of 1:1000 IM
   ii. Airway maintenance and oxygenation
   iii. Resuscitate hypotensive patients with IV fluids
   iv. Diphenhydramine, Dexamethasone, Zantac
b. **Acute Hemolytic Transfusion Reaction (AHTR)**
   i. Immediately STOP the transfusion
   ii. Initial Treatment

(a) Secure and maintain airway
(b) Begin an IV infusion of crystalloid.
NOTE: DO NOT run any fluid through the line that was carrying blood.
(c) The goal of fluid resuscitation is to maintain a urine output of 100-200ml/hr until the urine is clear of hemolyzed RBCs.
(d) Administer mannitol 20% (Osmitrol®) 20gm IV over 5 minutes using a blood administration filter to prevent infusion of mannitol crystals. If diuresis does not occur, repeat the 20gm dose once. The patient should receive a Foley catheter to monitor urine output.
(e) If mannitol 20% (Osmitrol®) is unavailable or does not produce diuresis, administer furosemide (Lasix®) 40-80mg initially and titrate later doses to maintain urine output of 100-200cc/hr.
(f) However, if urine output is not obtained within 2-3 hours of administration of fluid, consider the development of Acute Renal Failure and discontinue further fluids.
(g) Consider using acetaminophen (Tylenol®, Ofirmev® [IV]) 1gm PO, PR, or IV (every 6 hours to treat discomfort associated with fevers. (Avoid the use of aspirin or other NSAIDS).
(h) Administer 25-50mg of diphenhydramine (Benadryl®) IM, or IV to treat associated histamine release from AHTR & help manage the chills/rigor.
NOTE: Antihistamine (IV administration) must never be mixed with blood or blood products in the same transfusion lines.

iii. **SAVE** remaining donor blood and any typing information available & evacuate w/ patient. This will allow for ABO/further diagnostic testing at the MTF.

c. Febrile Non Hemolytic Reactions

i. Treat with antipyretics. Acetaminophen (Tylenol®, Ofirmev® [IV]) 1gm PO, PR, or IV (avoid the use of aspirin and other NSAIDS).
ii. If symptoms abate and there is no evidence of an acute hemolytic reaction consider restarting the transfusion.
iii. Pretreatment with antipyretics and antihistamines is recommended in this protocol and commonly done although there is no evidence that is decreases the incidence of fever and urticaria associated with transfusions.

d. Urticarial Reactions

i. Treat with 25-50mg diphenhydramine (Benadryl ®) IM or PO.
ii. If symptoms abate and there is no evidence of an acute hemolytic reaction consider restarting the transfusion.

Administer Fresh Frozen Plasma (FFP)

1. Keep FFP frozen at -0.4 degrees F (-18 degrees C) or below.

2. Do not rough handle FFP before thawing because the bags can be easily cracked, broken, or damaged.

3. FFP should be thawed in a water bath with the FFP bag wrapped in a plastic overwrap bag to protect the ports from contamination and to lessen the risk of contaminating the water bath if the FFP bag is broken or cracked (See Enclosure #2: Suggested Packing List). Thaw FFP at 98.6 degrees F (37 degrees C) or by using a method and/or equipment that is intended (validated) for such use. Do not exceed 107 degrees F (42 degrees C).

4. Turn the plasma during the thawing process and ensure that all fibrin clots are dissolved.

5. The plasma should be administered as rapidly as possible after thawing. Keep plasma refrigerated at 33-43 degrees F (1-6 degrees C) prior to administration.

6. Thawed plasma can be stored for 3 days at 33-43 degrees F (1-6 degrees C) and then should be returned to the MTF for use. If thawed plasma cannot be returned to and MTF for use then it should be discarded after storage at 33-43 degrees F (1-6 degrees C) for 5 days. Thawed plasma can only be kept for 30 minutes at room temperature (68-75 degrees F [20-24 degrees C]).

7. **AB is the universal donor for plasma.**

8. FFP is normally supplied as type AB or A.

9. Rh factor is not a concern when administering FFP.

10. Ensure compatibility of recipient.

11. Administer 2 units of FFP and then begin administering PRBCs in a 1:1 ratio if available. You may bolus or pressure infuse FFP immediately.

VI. TACTICAL COMBAT CASUALTY CARE (TCCC)

8. Triage Categories

IMMEDIATE
This category includes those casualties who require an immediate LSI and/or surgery. Put simply, if medical attention is not provided they will die. **The key to successful triage is to locate these individuals as quickly as possible. Casualties do not remain in this category for an extended period of time. They are either found, triaged and treated, or they die!** Hemodynamically unstable casualties with airway obstruction, chest or abdominal injuries, massive external bleeding, or shock deserve this classification.
DELAYED
This category includes those wounded who are likely to need surgery, but whose general condition permits delay in surgical treatment without unduly endangering the life, limb, or eyesight of the casualty. Sustaining treatment will be required (e.g., oral or IV fluids, splinting, administration of antibiotics and pain control), but can possibly wait. Examples of casualties in this category include those with no evidence of shock who have; large soft tissue wounds, fractures of major bones, intra-abdominal and/or thoracic wounds, and burns to less than 20% of total body surface area (TBSA).
MINIMAL
Casualties in this category are often referred as the "walking wounded." Although these patients may appear to be in bad shape at first, it is their physiologic state that tells the true story. These casualties have minor injuries (e.g., small burns, lacerations, abrasions, or small fractures) that can usually be treated with self- or buddy-aid. These casualties should be utilized for mission requirements (e.g., scene security), to help treat and/or transport the more seriously wounded, or put back into the fight.
EXPECTANT
Casualties in this category have wounds that are so extensive, that even if they were the sole casualty and had the benefit of optimal medical resources, their survival would be highly unlikely. Even so, expectant casualties should not be neglected. They should receive comfort measures and pain medication if possible, and they deserve re-triage as appropriate. Examples of expectant casualties are the unresponsive with injuries such as penetrating head trauma with obvious massive damage to the brain.

EVACUATION PRECEDENCE

URGENT / CATEGORY A (WITHIN 2 HOURS) *	PRIORITY / CATEGORY B (WITHIN 4 HOURS)	ROUTINE / CATEGORY C (WITHIN 24 HOURS)
• Significant injuries from a dismounted IED attack • Gunshot wound or penetrating shrapnel to chest, abdomen, or pelvis • Any casualty with ongoing airway difficulty • Any casualty with ongoing respiratory difficulty • Unconscious casualty • Casualty with known or suspected spinal injury • Casualty in shock • Casualty with bleeding that is difficult to control • Moderate/Severe TBI • Burns greater than 20% Total Body Surface Area	• Isolated, open extremity fracture with bleeding controlled • Any casualty with a tourniquet in place • Penetrating or other serious eye injury • Significant soft-tissue injury without major bleeding • Extremity injury with absent distal pulses • Burns over 10-20% of Total Body Surface Area	• Concussion (mild traumatic brain injury) • Gunshot wound to extremity - bleeding controlled without tourniquet • Minor soft-tissue shrapnel injury • Closed fracture with intact distal pulses • Burns over < 10% Total Body Surface Area

* Note that by Secretary of Defense directive, all casualties categorized as CAT A in the Afghanistan theater of operations should be able to be evacuated to an MTF with a surgical capability within 60 minutes from the time that the evacuation mission is approved.

I – INJURY OR ILLNESS	Injury or Illness
S – SYMPTOMS AND VITAL SIGNS	A – Airway status B – Breathing rate C – Pulse rate D – Conscious/Unconscious E – Other signs
T – TREATMENT GIVEN	Such as Tourniquet/Time Applied Drugs administered

VII. CANINE PROTOCOL(Military & DOD working Dogs)

K-9 Trauma Management Protocol

SIGNS AND SYMPTOMS for Shock:
1. Pale color in gums, capillary refill time greater than 2 seconds
2. Dry lips and gums, dehydration
3. Excessive drooling in some poisoning cases
4. Weak femoral pulse
5. Rapid heart rate of 150-200 beats per minute
6. Cool extremities
7. Hyperventilation, rapid breathing generally over 25 breaths per minute (panting may or may not be normal)
8. Confusion, restless, anxiousness
9. General weakness

Advanced stages of shock:
1. Continued depression and weakness to the point of not being able to move or becoming unresponsive or unconscious
2. Dilated pupils
3. Capillary refill time greater than 4 seconds
4. White mucous membranes
5. Rectal temperature below 98° F.

MANAGEMENT:

1. **MARCHE** Protocol
2. **Muzzle, M**assive hemorrhage: Control bleeding per TCCC standards, Morphine
   A. Muzzle
   B. Massive hemorrhage: Control bleeding with direct pressure and pressure dressings. Tourniquets are not as effective in dogs due to anatomical differences. All hemostatic agents used in humans are safe for use in dogs.
   C. Morphine: 10-30mg IM. May cause vomiting and respiratory depression. Use Naloxone (0.02mg/kg) for reversal if necessary.
3. **A**irway
   A. An injured dog or an animal in shock may not recognize you. The dog may bite you out of pain or fear. If the dog is having trouble breathing or panting heavily, **DO NOT** apply a muzzle. If a

muzzle is placed on the dog it must be monitored at all times and removed at the first sign of overheating or vomiting because they can easily aspirate. Get help if possible from someone who can help hold the dog, so you can do an examination and/or treat the dog.

1) Carefully pull the tongue out of the animal's mouth.
2) Even an unresponsive dog may bite by instinct!!
3) Make sure that the neck is reasonably straight; try to bring the head in-line with the neck.
4) Do not hyperextend in cases where neck trauma exists

B. Intubation or tracheostomy if necessary to assure airway

1) Do not attempt to intubate a conscious animal, personnel must have prior training. ET tube size can range from 7-10.

C. If intubation is not possible, then attempt tracheostomy.

D. After achieving a patent airway, one must determine whether the animal is breathing, and whether this breathing is effective.

E. **AIRWAY CONSIDERATIONS:**

1) Size 7mm to 10mm cuffed endotracheal tube, secure with gauze or IV tubing. Tie over nose.
2) Flow by oxygen – secure airline to muzzle.
3) Field expedient O_2 masks.
4) Nasal trumpets are ineffective in canines

4. **R**espirations

A. Look, Listen, and Feel

B. If not breathing, ventilate the animal by closing the mouth, and performing mouth-to-nose ventilations. If patient is intubated or has tracheostomy, ventilate the animal using an Ambu-bag.

C. Ventilate at 20 breaths per minute.

D. If available, use supplemental oxygen

E. Needle thoracentesis: Place the dog in the lateral recumbency, go midway between sternum and spine between the 7th and 9th ribs. Use a 14G 3.25in needle. Perform needle decompression on both sides.

5. **C**irculation

A. Be sure that there are no major (pooling/spurting blood) points of bleeding. Control as necessary.

B. Hemorrhagic Shock Fluid Resuscitation (Administration Routes):

1) Primary route is IV
2) Secondary route is IO (Tibia or Humerus) on a sedate or unconscious dog only.

C. Incorporate crystalloids and colloids as needed

1) Bolus of crystalloid, 10-20ml/kg, reassess and repeat a maximum of 2 times
2) Bolus of colloid, 5-10ml/kg given once over 20-30 minutes.

D. The targeted endpoint for resuscitation should be to achieve and maintain permissive hypotension.

E. Blood transfusion (dog-to-dog), if available.

1) For the first transfusion in a trauma/field situation it is generally safe to give any type of blood without typing or cross-matching.
2) Collect no more than 20% blood volume (collect 1 unit/450ml from typical size working dog). Perform a sterile prep and use the jugular vein for collection.
3) In a trauma/field situation you will usually administer the whole unit. Human blood transfusion guidelines apply for rate and monitoring requirements.

6. **H**ypothermia: Prevent loss of body heat. Dry the fur. Use a hypothermia blanket. Watch for overheating.

7. Evacuation and Everything Else

A. TXA – Administer 10-15ml/kg IM or slowly IV

B. Analgesia

1) Morphine: Administer 0.5-1mg/kg IM or IV, may cause vomiting

2) Hydromorphone/Dilaudid: Administer 0.1-0.2mg/kg IM or IV, may cause vomiting
3) Fentanyl: Administer 3-4mcg/kg IV; Can also use a fentanyl lollipop inserted in the rectum secured with tape to the tail base
4) Naloxone: Opiod reversal , administer at 0.02-0.04mg/kg IV, IM, or SQ

C. Antibiotic Therapy for Penetrating Wounds
1) Ceftriaxone (Rocephin) 1gm IV / IM daily
2) **E**rtapenem (Invanz) 500mg IV / IM two times a day

Monitoring:

K-9 EVALUATION AND TREATMENT PROTOCOL

VITAL SIGNS OF CANINES:

Parameter	Value	Parameter	Value
Pulse	60-120 bpm	HCT/PCV	37-55%
Respiration	8-24 bpm	SPO2	95-100%
Temp	100-102.5 F	ET CO2	35-45 mm Hg
CRT	<2 sec	Total Protein	5-7.5g/dl

1. Temperature:
   A. Normal Rectal Temp is 100-102.5° F.
   B. Temperature after exercise: 103-106° F. Temperature should return to normal within 15 minutes after completion.
2. Pulse
   A. Normal pulse rate will vary from 60-120bpm. Can beat up to 150 with exercise.
   B. The pulse rate and respiratory rate will vary from dog to dog, and will also vary if the dog is at rest or working.
   C. The femoral artery is located on the inside of a dog's rear thighs. Take your hand as if you were passing someone a plate, grab the dog on the front of their thigh with your fingers inside the thigh, and palpate the artery.
3. Normal respiratory rate for an adult dog will vary between 8-24 respirations per minute
4. Capillary refill time: less than 2 seconds.
5. Mucous membrane color: generally pink.

SPECIFIC WEIGHT RELATED DRUG DOSES ARE AT THE END OF THIS PROTOCOL. MOST DOG HANDLERS WILL CARRY A DRUG CARD FOR THE DOG.

MONITORING:

1. Pulse Ox – Placed on tongue, ear, or other non-pigmented highly vascular area such as the lip, vulva, or prepuce.
2. EKG – Alligator clips behind each elbow and above left knee. If you do not have alligator clips place the buttons or leads behind the largest pad on the foot. Sticky pads can also be placed on the largest pad on the foot of the left and right forelimbs and the left hindlimb.
3. Animals do not have palpable carotid pulses. You can obtain a femoral pulse in the inguinal crease.
4. End Tidal CO2 – Measure the same way you do in human patients. Normal value 35-45mm Hg.

Femoral Pulse Location:

IV/IM Sites

IM and SQ INJECTION SITES:

IM Injections

1. Gluteal Site: palpate muscle belly between fingers. Insert needle into muscle; pull back on plunger to ensure no blood is present. Inject if no blood and reposition needle if blood is present.

2. Epaxial Site: Place hand on back with middle finger located on spine and thumb just in front of the pelvis. Muscle belly will be where your index finger naturally falls.

Subcutaneous Injections

1. Lift skin between the shoulder blades, insert needle at 45 degree angle.

IV SITES:

Usually the easiest/best vein to use for a K-9 IV is the one found on their forelegs. The cephalic vein is located on the middle of the foreleg. This is the most commonly used vein for fluid administration and IV delivery of drugs.

If the person occluding the vein for you rolls it laterally, this will place the vein directly on top of the dog's leg, easing access.

Maintain a firm hold on the dogs leg as you place the catheter, as they will pull away from you while placing the catheter.

Start distally on the vein. If you blow the vein, move more proximally and attempt the IV.

An 18 gauge 1 ½" catheter can be used in both the cephalic and the saphenous veins.

In the hind leg, the lateral saphenous vein is used. This vein is harder to maintain and secure.

In both procedures use plenty of tape to secure the IV line. Your patient will try to pull it out. If they are ambulatory, movement will often dislodge the IV. IVs in conscious dogs must be monitored.

Cephalic Vein

Saphenous Vein

Hydration Status

HYDRATION STATUS:

1. Normal Hydration: Pick up skin and release. It should return to the original position within 1 second.
   A. Capillary Refill Time (CRT) is measured by pressing on the gums over the canine tooth. Using one finger, press down firmly until the gums turn white under your finger and release. Anything over two seconds is considered too long. Also, note the normal color of your dog's gums and mouth. Dog's gum color may vary from black, pink, brown or any combination of those colors.
2. Dehydration:
   A. 6-8% dehydration – loss of skin elasticity, tacky gums, mildly prolonged CRT
   B. 10-12% dehydration – tented skin, dry gums, prolonged CRT, sunken eyes, increased HR, rapid/weak pulses. Consider a 10-12% dehydration an emergency.
3. Dehydration Fluid Replacement
   A. Estimate dehydration
      1) 5% give 1000ml bolus IV
      2) 10% give 1500ml bolus IV
   B. Fluid choice is normal saline or Lactated Ringer's Solution. Oral fluid consumption is the best way to rehydrate a dog.

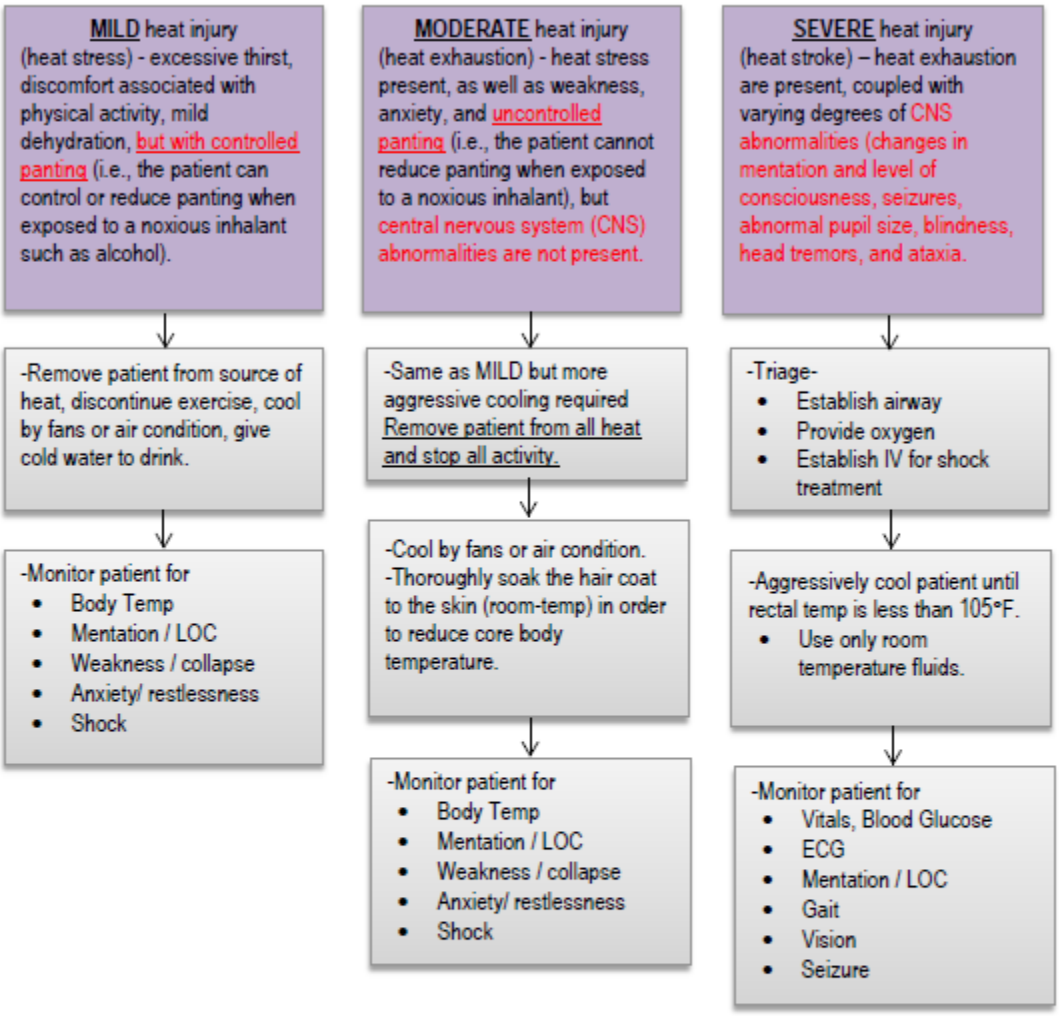
RESTRAINT (SOF medical personnel should work with handler to learn muzzling techniques):

1. Always muzzle dog when working on them.
2. Physical restraints with muzzles or improvised muzzles
   A. Field expedient muzzle:
      1) Kerlix is wrapped around the snout several times and then tied behind the head.

      2) The leash is wrapped around the snout and held tightly.

3. Chemical restraint if needed to protect handler and medic
   A. Dexdomitor (if not traumatic injury) reversed with Antisedan. Dexdomitor after onset gives 20-30 minutes of good sedation when administered with labeled dose.
   B. For mild sedation, a combination of Midazolam (0.3mg/kg) plus Ketamine (5mg/kg) can be administered IM or IV.
   C. For deep sedation, a combination of Morphine (1mg/kg) plus Midazolam (0.3mg/kg) plus Ketamine (5mg/kg) can be administered IM.
      1) Dilaudid/Hydromorphone (0.1mg/kg) may be used in place of Morphine.

MWD Heat Injury Treatment



MILD heat injury
(heat stress) - excessive thirst, discomfort associated with physical activity, mild dehydration, but with controlled panting (i.e., the patient can control or reduce panting when exposed to a noxious inhalant such as alcohol).
-Remove patient from source of heat, discontinue exercise, cool by fans or air condition, give cold water to drink.
-Monitor patient for
Body Temp
Mentation / LOC
Weakness / collapse
Anxiety/ restlessness
Shock
MODERATE heat injury
(heat exhaustion) - heat stress present, as well as weakness, anxiety, and uncontrolled panting (i.e., the patient cannot reduce panting when exposed to a noxious inhalant), but central nervous system (CNS) abnormalities are not present.
-Same as MILD but more aggressive cooling required Remove patient from all heat and stop all activity.
-Cool by fans or air condition.
-Thoroughly soak the hair coat to the skin (room-temp) in order to reduce core body temperature.
-Monitor patient for
Body Temp
Mentation / LOC
Weakness / collapse
Anxiety/ restlessness
Shock
SEVERE heat injury
(heat stroke) – heat exhaustion are present, coupled with varying degrees of CNS abnormalities (changes in mentation and level of consciousness, seizures, abnormal pupil size, blindness, head tremors, and ataxia.
-Triage-
Establish airway
Provide oxygen
Establish IV for shock treatment
-Aggressively cool patient until rectal temp is less than 105°F.
Use only room temperature fluids.
-Monitor patient for
Vitals, Blood Glucose
ECG
Mentation / LOC
Gait
Vision
Seizure

Clinical Pearls:

- **PANTING** is the only significant cooling mechanism for dogs.
- **NO** specific body temperature defines heat stroke in MWD's. Normal rectal temperature is 99.0° to 102.5° F in the MWD. Temperatures as low as 105.8°F have been associated with pathology. Most commonly, heat stroke is seen in MWDs with rectal temperatures greater than 107°F.
- **DO NOT** use of cold intravenous fluids, ice packs, or ice-water baths for cooling.
- Once the MWD's body temperature is <103° **CEASE** all cooling efforts and monitor for rebound hypothermia.

MWD CPR Management

Cardiopulmonary Arrest Confirmed

BEGIN BASIC LIFE SUPPORT- SUSTAIN CPR for 2-3 minute cycles

- **Circulation**- Chest compressions, FAST and HARD, 100 compressions per minute
- **Airway**- Clear airway and intubate; perform tracheostomy if obstructed airway
- **Breathing**- Manually ventilate with 100% O_2 at 8-10 breaths per minute

BEGIN ADVANCED LIFE SUPPORT
ECG (determine arrest rhythm)
IV / IO access for drug delivery

VF or VT

- Defibrillate- **2-5 J/kg**
- Resume chest compressions x 1 cycle
- Defibrillate twice more, with 1 compression cycle between each counter-shock, if refractory
- Drug therapy if counter-shock no successful:
  - Epinephrine **0.01 mg/kg** IV/IO
    or
    Vasopressin **0.8 U/kg** IV/IO **once**
    and
  - Lidocaine **2 mg/kg** IV/IO
    or
  - Amiodarone **5-10 mg/kg** IV/IO
- Repeat counter-shock (2 x initial energy) if refractory

ASYSTOLE/ BRADYCARDIA/ PEA

- Drug therapy:
  - Atropine **0.04 mg/kg** IV/IO
    and
  - Epinephrine **0.01 mg/kg** IV/IO
    or
  - Vasopressin **0.8 U/kg IV/IO once**

CPR EMERGENCY DRUG CACLUATION (Quick Reference)

Caution: you must first validate the drug concentrations on the bottle is the same as on this quick reference chart.

					Weight (Pounds)	50	60	70	80	90	100
					Weight (Kg)	22.7	27.3	32	36.3	41	45.5
DRUG/ACTION	[CONC]		DOSE		ROUTE	ml	ml	ml	ml	ml	ml
Vasopressin	20	units/ml	0.80	U/kg	IV / IO	0.91	1.09	1.28	1.45	1.64	1.82
Epinephrine (1:1,000)	1	mg/ml	0.01	mg/kg	IV / IO	0.23	0.27	0.32	0.36	0.41	0.46
Epinephrine (1:10,000)	0.1	mg/ml	0.01	mg/kg	IV / IO	2.27	2.73	3.20	3.63	4.10	4.55
Atropine	0.4	mg/ml	0.04	mg/kg	IV / IO	2.27	2.73	3.20	3.63	4.10	4.55
Lidocane (1%)	10	mg/ml	2.00	mg/kg	IV / IO	4.54	5.46	6.40	7.26	8.20	0.91
Amiodarone	50	mg/ml	5.00	mg/kg	IV / IO	2.27	2.73	3.20	3.63	4.10	4.55
Magnesium Sulfate (0.5 g/ml)	500	mg/ml	30.00	mg/kg	IV	1.36	1.64	1.92	2.18	2.46	2.73
Sodium Bicarbonate (8.4%)	1	mEq/ml	1.00	mEq/kg	IV	22.70	27.30	32.00	3.63	41.00	45.50
Defibrillate	2-5	J/kg	2.00	J/kg	External	45.40	54.60	64.00	72.60	82.00	91.00

Drug	Dose	Dose per 25kg K9
K9 - ALS DRUGS		
Epinephrine	0.01 mg/kg (1:1000) IV/IO, IM, IT q 3-5 min	0.25 mg
Atropine	0.04 mg/kg IV/IO, IM, IT q 3-5 min	1 mg
Lidocaine	2 mg/kg IV/IO, IT (slow IV/IO push over 1-2 min)	50 mg
NAVEL (naloxone, atropine, vasopressin, epinephrine, lidocaine) may be given via ETT (Intratracheal or IT) For IT administration increase IV dose 2–3× and dilute with 0.9 % saline or sterile water		
K9 - ANESTHETICS / CHEMICAL RESTRAINT		
Ketamine	2 - 4 mg/kg IV or 5 – 8 mg/kg IM *(with benzodiazepine)*	50 - 100 mg IV / IO 125 – 400 mg IM
Etomidate	1 mg/kg *(Administer a benzodiazepine prior to Etomidate)*	25 mg
Diazepam*(Valium®)	0.2 - 0.4 mg/kg IV/IO/IM or per rectum	5 - 10 mg
Midazolam* (Versed®)	0.2 - 0.5 mg/kg IV/IO/IM	5 - 10 mg
Lorazepam* (Ativan®)	0.2 mg/kg IV/IO/IM or intranasal once	5 mg
**(NOTE: Do not use Benzodiazepines alone for restraint, may cause paradoxical excitement)*		
K9 - OPIOIDS / ANALGESICS		
Fentanyl	Bolus or Loading Dose: 2-5 mcg/kg IV/IO/IM q 30 min Infusion: 3 – 6 mcg/kg/h	50 - 125 mcg 75 - 150 mcg/h
Hydromorpone (Dilaudid)	Bolus or Loading Dose: 0.1 mg/kg IV/IO/ IM q 2 - 4 h Infusion: 0.01 – 0.05 mg/kg/h	2.5 mg 0.25 - 1.25 mg/h
Morphine	Bolus or Loading Dose: 0.2–0.5 mg/kg IV/IO/IM q 1-4h ***Administer IV/IO Slowly over 3 - 5 min***	5 - 10 mg
	Infusion: 0.1 – 0.3mg/kg/h *(2.5 - 7.5 mg / h)*	2.5- 7.5 mg/h
*NOTE: **a)** Oral opiates tend not to be effective in K9's; **b)** Always start low and titrate to effect; **c)** monitor for respiratory depression and hypotension; **d)** have naloxone on hand for opiate reversal if needed; **e)** consider administering an antiemetic prior to the opiate		
DRUG REVERSALS		
Flumazenil (Romazicon®)	0.02mg/kg IV/IO; repeat every 30 - 60 min as needed	0.5 mg
Nalaxone (Narcan®)	0.04 -0.1 mg/kg IV/IO/IM/IT; repeat as necessary	1.0 - 2.5 mg

Drug	Dose	Dose per 25kg K9
GASTROPROTECTANTS (Antacids)		
Famotidine (Pepcid®)	0. 5 - 1.0 mg/kg IV or PO, q 12 h	10 -25 mg
Ranitidine (Zantac®)	2mg/kg IM or slow IV/IO q8-12h	50 mg
ANTI-EMETICS (Antinausea)		
Ondansetron (Zofran®)	0.2 - 0.5 mg/kg PO or IV (slowly IV over 2-15 minutes) q 8 h	5 - 10 mg
Promethazine (Phenergan®)	0.2 – 0.5 mg/kg PO q 6-8 h **low oral bioavailability in K9s*	5 - 10 mg
MISCELLANEOUS		
Albuterol	*Oral:* 0.02 – 0.05 mg/kg PO q8-12h	0.5 - 1.25 mg
	Inhaler: 2-4 puffs q 20 min until resolution of clinical signs	**Requires spacing chamber /mask*
Cetirizine	1 mg/kg PO q12-24 h	10 – 20 mg
EPI-PEN®	0.15 (pediatric) or 0.3 mg (adult) unit dose	0.15 - 0.3 mg IM
Dextrose 50% (glucose)	1 ml/kg (0.5 gm/kg) IV slowly *(dilute 1:2 with saline to make 25% solution)*	25 mL (25 gm)
Diphenhydramine (Benadryl®)	2 - 4 mg/kg q 8 - 12 hour IM or PO	50 - 100 mg
Lidocaine 1% without Epi	1 mg/kg injected for local anesthesia	25 mg (2.5 mL)
Mannitol 25% (250 mg/mL)	0.5 - 1.4 g/kg IV/IO over 20 - 30 min	12.5 - 35 g
Sodium Bicarbonate	1 mEq/kg, once, diluted IV, (for CPA > 10 min + pH< 7)	25 mEq
Tetracaine 0.5% (*Proparacaine*)	1 -2 gtts / eye	1 -2 gtts / eye
Tranexamic Acid	10 mg/kg IV, slow infusion	25 mg
*AVOID **NON-STEROIDAL ANTI-INFLAMMATORY** medications (e.g. aspirin, ibuprofen, naproxen, ketorolac, etc.) in the trauma patients		
ANTIBIOTICS		
Ampicillin +/- sulbactrum	20 – 40 mg/kg IV /IM q6-8h	500 – 1000mg
Cephalexin (Rilexine®)	22 – 30 mg/kg **PO** q 12h (ORAL)	500 – 1000 mg
Cefazolin (Ancef)	20 – 22 mg/kg IV or IM (large muscle)	500 – 1000 mg
Cefotetan (Cefotan)	30 mg/kg IV or SC q8h (Do not give IM – painful)	750 – 1000 mg
Ceftriaxone (Rocephin®)	25 - 50 mg/kg **IV** q24 h or 50 mg/kg **IM** / SC q 12 – 24 h	1000 mg

K9 Daily Water Requirements =
132 x Body Weight(kg)$^{0.75}$ or 40 - 50 mL/kg/day

K9 TECC Shock Fluid Resuscitation Recommendations

- Avoid large-volume isotonic crystalloid resuscitation to prevent exacerbating resuscitative injury
- Reassess perfusion parameters after each fluid bolus
- Reassess the K9 casualty frequently to check for recurrence of shock
- If shock recurs, recheck all external hemorrhage control measures to ensure that they are still effective and repeat the fluid resuscitation as outlined above.

Heat Related Illness

- Move from hot area into shade or air-conditioned area
- As feasible, remove muzzles, harnesses, tactical gear, etc.
- Place on cool surface to promote conductive cooling
- Offer cool water and encourage drinking if K9 is alert and conscious
- Start **active external cooling**
  - If air-conditioning not available, blow a circulating fan over K9 (if available)
  - Place cold compresses or ice packs (wrapped in a towel) on the head and neck as well as in the armpits (axillae) and groin; **NOTE**: avoid placing ice packs on the limbs as this shunts hot blood back to the body core.
  - Immerse in cold water bath or Douse or spray body with cold water
- Place an IV / IO catheter and start IV / IO fluids to restore perfusion
- STOP active cooling when rectal temperatures reach 103.5 - 104°F.
  - Dry K9 off, place on dry surface, avoid direct application of air on you K9 from circulating fans or air-conditioning.
- **Monitor temperature** every ten minutes for at least the next few hours as body temperature may continue dropping to the subnormal range or rise excessively again

Options for Shock Resuscitation are in the Order of Preference

1. **K9-specific Fresh or Stored Whole Blood, 450 – 500 mL** (*1 unit*)
2. **K9-specific pRBC: FFP @ 10 mL/kg** of each *(Ex: 25kg K9 = 250 mL pRBC: 250 mL FFP)*
   DO NOT give human blood products to an injured K9
3. **Colloid only** *(*low-molecular weight 130/0.4 preferred*)*: **125 - 250 mL** (5 – 10 mL/kg)
   - *Repeated in **125 mL** aliquots to achieve palpable femoral pulse.*
   - *Not to exceed of a total volume of **500 mL***
4. **Hypertonic Saline (HTS) + Synthetic Colloid**
   - **75 mL** HTS : **75 mL** Colloid = **150 mL** total volume *(5 mL/kg HTS : 5 mL/kg Colloid)*
   - Limit **HTS** to no more than **TWO** aliquots
   - **NOTE**: Avoid using HTS in situations involving *uncontrolled hemorrhage* where definitive hemostasis cannot be achieved.
   - **With concurrent TBI**: restores perfusion and provides hyperosmotic therapy
5. **Isotonic crystalloid Only**: **500 mL** (20 mL/kg)
   - Repeated in 250 – 500 mL aliquots to achieve palpable femoral pulse.
   - Not to exceed of a total volume of 1000 mL
   - **Preferred** crystalloid is a balanced, buffered isotonic solutions
     - Lactated Ringers, Plasma-Lyte A, Normosol-R - **Avoid 0.9% NaCl**

Fluid Resuscitative Goals

Discontinue fluids when the following end-points have been achieved:

Non-Hemorrhagic or Controlled Hemorrhagic Shock
- Palpable femoral pulse & improved mentation MAP = > 65 mm Hg; **SBP 80 – 90 mm Hg**

Uncontrolled / Noncompressible Hemorrhagic Shock
- Consider *Hypotensive Resuscitation*
- Palpable femoral pulse & improved mentation AND/OR **MAP = 50 - 60 mm Hg; SBP ~80 mm Hg**
- *Maintained until **definitive hemostatic** control is achieved*

Hemorrhagic Shock with Neurological Trauma (*TBI*)
- K9 casualty with an altered mental status due to suspected TBI with a weak or absent peripheral pulse:
- Resuscitate to restore & maintain a palpable femoral pulse. If BP monitoring is available, maintain a target **SBP ≥ 90 mm Hg**

XIII. MEDICATION REFERENCE

ACTIVATED CHARCOAL	
Class	Absorbent, Antidote
Indications	Oral poisoning and medication overdose.
Contraindications	GI obstruction, GI bleed or perforation, patients with an unprotected airway
Dose & Route	**1 to 12 years:** 25 to 50 grams **>12 years and adults**: 25 to 100 grams Given PO or via NG or OG tube. Agitate contained thoroughly and mix with water to make a slurry prior to administration.
Side Effects	May induce nausea, vomiting, constipation or diarrhea.

ADENOSINE	
Class	Antidysrhythmic
Indications	PSVT refractory to vagal maneuvers, including dysrhythmias associated with bypass tracts as WPW syndrome.
Contraindications	2° or 3° AVB's, Sick Sinus Syndrome, A-fib/flutter and VT usually not converted with Adenosine.
Dose & Route	**Adult:** 6mg rapid IV push followed by a 20cc flush. 2nd dose at 12mg may be administered in 1-2 minutes 3mg IV initially for patients taking carbamazepine or dipyridamole, heart transplant, or if adenosine is being administer through a central line. **Peds:** 0.1mg/kg rapid IV push (Max= 6mg), double the 2nd and 3rd doses (Max= 12mg).
Side Effects	Transient periods of new arrhythmia after cardioversion, chest pressure/discomfort, SOB, Nausea, chest pain, Diaphoresis, Flushing, HA, Palpitations, Paresthesia's, neck discomfort

ALBUTEROL	
Class	Sympathomimetic, Bronchodilator, Beta-2 selective
Indications	Asthma, bronchospasm, exercise-induced bronchospasm, hyperkalemia
Contraindications	Hypersensitivity. Symptomatic tachycardia dysrhythmias.
Dose & Route	**Bronchospasm**: 2.5 to 5mg diluted in 3ml of NS administered by nebulizer Q 20min x3 doses or 10 to 15mg/hour as continuous nebulization **Hyperkalemia**: 10 to 20mg nebulized over 10 minutes
Side Effects	Anxiety, tremor, chest pain, diaphoresis, dizziness, HA, nausea, palpitations, restlessness, tachycardia.

AMIODARONE	
Class	Antiarrhythmic Class III
Indications	Initial treatment and prophylaxis of recurring VF and hemodynamically unstable VT.
Contraindications	Cardiogenic shock, iodine hypersensitivity, bradycardia, 2° and 3° AVB
Dose & Route	VF/VT Cardiac arrest: **Adult**: 300mg IV/IO push, second dose of 150mg IV/IO push if needed **Peds:** 5mg/kg (Max 300mg) IV/IO push, may repeat twice (Max total dose=15mg/kg) Life-Threatening arrhythmias WITH pulse: **Adult:** 150mg IV over 10 min, may repeat if necessary **Peds:** 5 mg/kg IV (Max 300mg) over 20-60 min, may repeat twice up (Max total=15mg/kg) Maintenance Infusion after return of spontaneous resuscitation: 360mg over 6°, then 540mg over 18°
Side Effects	Bradycardia, flushing, HA, hypotension (rapid infusions), Vertigo, N/V, QT prolongation, epithelial keratopathy, pulmonary toxicity

ASPIRIN	
Class	Analgesic, anti-inflammatory, anti-pyretic, anti-platelet
Indications	Mild to moderate pain or fever. Chest pain (suspected angina or AMI) Prevention of AMI or reinfarction.
Contraindications	Children with flu-like symptoms, Hypersensitivity to NSAIDS.
Dose & Route	STEMI/NSTEMI: PO: (4) 81mg chewable tablets (324mg) Or adult 325mg non-enteric coated Rectal: 600mg suppository for those who can't take PO
Side Effects	Anaphylaxis, pulmonary edema, GI bleeding, Heartburn, coma, confusion, dizziness, tinnitus.

ATROPINE	
Class	Parasympatholytic (anticholinergic) agent
Indications	Symptomatic sinus bradycardias Organophosphate or nerve gas poisoning
Contraindications	There are no contraindications listed in the manufacturer's labeling
Dose & Route	*Bradycardia:* Adult: 0.5 mg IV/IO repeat Q 3-5min (Max total dose=3mg) Peds: 0.02mg/kg IV/IO Q 3-5 min (Minimum dose=0.1mg, Max SINGLE dose=0.5mg, Max TOTAL dose=1mg) *Organophosphate and nerve gas poisoning:* Adult: 1 to 6 mg IV/IM/ET Q3-5 minutes prn, double the dose if no response from previous dose. Peds: 0.05 to 0.1mg/kg IV/IM/ET Q 5-10 minutes prn, double the dose if no response from previous dose
Side Effects	Anticholinergic effects (dry mouth, blurred vision, photophobia, urinary retention, and constipation). Dizziness, Dysrhythmias, Flushing, HA, Hot, dry skin, Nausea/vomiting. Palpatations. Tachycardia. Paradoxical bradycardia if pushed too slowly or in dose <0.5mg in adults or <0.1mg in peds.

CALCIUM CHLORIDE 10%	
Class	Electrolyte
Indications	Acute hyperkalemia, acute hypocalcemia, calcium channel and beta blocker OD, abdominal spasms associated with spider bites and portugese man-o-war stings. Magnesium sulfate OD.
Contraindications	Known or suspected digoxin toxicity
Dose & Route	Cardiac arrest or cardiotoxicity d/t hyperkalemia, hypocalcemia, or hypermagnesemia Adult: 500 to 1000mg IV over 3-5minutes, may repeat prn Peds: 20mg/kg IV/IO Max= 2000mg/dose, may repeat prn Beta-blocker OD (Refractory to first line treatments) Adult: 10% solution: 20mg/kg over 5-10min, followed by 20 to 50mg/kg/hr Ca channel blocker OD: Adult: 10% solution: 1 to 2 grams over 5 min Q10-20min, then 20 to 50mg/kg/hr Peds: 10 to 20mg/kg over 10-15min (Max=2000mg/dose) Q10-15min prn, followed by 20-50 mg/kg/hr Hypovolemic shock: Infused via a 10% solution, 1 gram over 10 minutes.
Side Effects	ADE due to rapid IV injections: bradycardia, cardiac arrest, hypotension, syncope, feeling abnormal, tingling sensation, hot flash

DEXTROSE 50% / 25%	
Class	Carbohydrate, Hypertonic solution
Indications	Altered LOC, Coma of unknown origin, Hypoglycemia (usually FSBS <70). Seizures of unknown origin.
Contraindications	Increased intracranial pressure or hemorrhage. Known or suspected CVA in absence of hypoglycemia. Hypersensitivity to corn
Dose & Route	Adult: 10 to 25G slow IVP, repeat if necessary. Peds: 0.5-1.0g/kg slow IVP. If D25 not available, dilute D50 1:1 with sterile water or saline for 25% concentration May repeat of necessary.
Side Effects	Irritation, burning, and pain at the injection site.

DIAZEPAM (Valium)	
Class	Benzodiazepine
Indications	Acute alcohol. Acute anxiety state. Pre-medication prior to counter shock or TCP. Seizure activity. Skeletal muscle relaxation.
Contraindications	Coma (except seizures or rigidity.) Respiratory depression. Acute narrow-angle glaucoma. Untreated open-angle glaucoma.
Dose & Route	Seizures (adult and peds): IV: 0.15mg/kg over 2 minutes (Max=10mg/dose). May repeat Q 5min prn Anxiety: Adult: 2 to 10 mg IV/IM; may repeat in 3-4 hours prn
Side Effects	Confusion. Drowsiness. Hypotension. N/V. Psychomotor impairment. Reflex tachycardia. Respiratory depression or arrest.

DILTIAZEM (Cardizem)	
Class	Nondihydropyridine Calcium Channel Blocker
Indications	Atrial fibrillation, flutter, and tachycardia with rapid ventricular response rate. PSVT.
Contraindications	2nd or 3rd degree AVB. AMI. Cardiogenic shock. Hypersensitivity. Hypotension. Within a few hours of IV Beta blocker use. Sick sinus syndrome. Short PR syndrome. Ventricular tachycardia. WPW syndrome. Wide complex tachycardia of unknown origin.
Dose & Route	Adult: 0.25mg/kg IV over 2 min. Repeat in 15 minutes if needed at 0.35mg/kg. Peds: Same as adult, but rarely used.
Side Effects	1st degree AVB. Bradycardia. Chest pain. CHF. Diaphoresis. Dizziness. Dyspnea. Headache. Hypotension. Nausea/vomiting. Peripheral edema

DIPHENHYDRAMINE (Benadryl)	
Class	Antihistamine
Indications	Acute extrapyramidal reactions. Dystonic reactions to phenothiazines. Moderate to severe anaphylaxis after epinepherine. Allergic symptoms.
Contraindications	Hypersensitivity. Nursing mothers.
Dose & Route	Adult: 25-50mg IM/IV Peds: 1 to 2mg/kg IM/IV (Max 50mg/dose)
Side Effects	Bradycardia. Disturbed coordination. Drowsiness. Dry mouth and throat. Paradoxical excitement in children. Sedation. Tachycardia. Thickening of bronchial secretions.

DOPAMINE (Intropin)	
Class	Sympathomimetic (Inotrope)
Indications	Adjunct treatment of Hypotension in the absence of Hypovolemia. Second line for symptomatic bradycardia (after atropine)
Contraindications	Hypovolemic shock without fluid resuscitation. Patients with Pheochromocytoma. Tachydysrhythmias. Ventricular Fibrillation.
Dose & Route	Adult and Peds: (Concentrations of 1600mcg/ml or 800mcg/ml) 400mg in 250ml=1600mcg/ml, 400mg in 500ml=800mcg/ml 800mg in 500ml=1600mcg/ml, 800mg in 1000ml=800mcg/ml *Renal Dose*: 1-5mcg/kg/min *Cardiac Dose:* 5-10mcg/kg/min *Vasopressor dose:* >10mcg/kg/min
Side Effects	Dose related tachycardia's, Hypertension, Increased myocardial O_2 demands (may increase ischemia), Palpitations, Excessive vasoconstriction

ETOMIDATE	
Class	Nonbarbituate hypnotic, anesthetic
Indications	Premedication for tracheal intubation or cardioversion.
Contraindications	Hypersensitivity
Dose & Route	Adult and Peds: 0.2-0.6mg/kg IV/IO over 30 seconds (usually 0.3mg/kg)
Side Effects	Adrenal Suppression, Apnea, Hiccups, Hypo/Hyperventilation, Pain at injection site, Bradycardia, HTN, Involuntary muscle movements, Tachycardia, Dysrhythmias, Hypotension, N/V

EPINEPHRINE	
Class	Sympathomimetic
Indications	1:1000: Anaphylaxis. Severe allergic reactions. Bronchial asthma. Exacerbation of COPD. Used in adult and pediatric cardiac arrest after 1:10,000. 1:10000: Anaphylactic Shock, Cardiac Arrest, Profound symptomatic bradycardia
Contraindications	There are no contraindications
Dose & Route	1:1000: (1 mg in 1 ml vial; See EPI 1:10,000 for cardiac arrest dosing regimens) *Hypersensitive Reactions (Intramuscular is preferred over SQ)* Adult: 0.2-0.5mg IM/SQ Q 5-15min Peds: 0.01mg/kg up to 0.3mg IM/SQ Q 5-15min 1:10000: (1mg in 10ml syringe) *Cardiac Arrest:* Adult: 1MG IVP every 3-5 Minutes (ETT 2-2.5 x IV dose) Peds: 0.1mg/kg (1:10,000) initial dose IV (0.1mg/kg of 1:1,000 ETT) Subsequent doses 0.1mg/kg of 1:1,000 IV/ET/IO *Anaphylactic reaction or bronchoconstriction:* Adult: 0.1mg over 5 minutes Peds: 0.1mcg/kg/min IV infusion (Refractory to IM dose; Max=10mcg/min) *Infusions for cardiac arrest or symptomatic Bradycardia:* Adult: Mix 2mg in 250mls of NS/D5W (8mcg/ml) and Infuse at 0.1mcg/kg/min for desired response. Peds: Mix 2mg in 250mls of NS/D5W (8mcg/ml), begin at 0.1mcg/kg/min, titrate up to 1mcg/kg/min Epinephrine Push Dose: 1/100,000 Draw 1ml of Epi 1/10,000 into 9 mL of a NS saline flush: 10mcg/ml Loading dose: 20 mcg/2ml Continuous Dosing: 10mcg/1ml/min to maintain SBP of >90 mmHg
Side Effects	Anxiousness, Chest Pain, Headache, Nausea, Palpitations, Restlessness, Tachycardia, Tremors. Tachyarrhythmia. Injection site tissue necrosis.

FENTANYL (Sublimaze)	
Class	Narcotic Analgesic
Indications	Adjunct to aesthesia for procedures, Severe pain
Contraindications	Hypersensitivity
Dose & Route	Adult: 25-100 mcg IV over 1 min Q30-60 minutes (May also give IM) Peds: 1-2 mcg/kg IV over 1 min Q30-60 minutes (May also give IM)
Side Effects	Altered LOC, Abnormal dreams, Arrhythmias, Confusion, Dizziness, Headaches, Hypotension, N/V, Respiratory depression

FUROSEMIDE	
Class	Loop diuretic
Indications	Pulmonary edema associated with CHF, hepatic or renal disease.
Contraindications	Anuria. Hypersensitivity. Hypersensitivity to sulfonamides. Hypovolemia/Dehydration. Uncorrected states of electrolyte depletion
Dose & Route	Adult: 20 to 40mg IV, may repeat in 1-2hours as same dose or increase by 20mg/dose Peds: 1mg/kg IV, May repeat in 2 hours or increase by 1mg/kg/dose (max 6mg/kg/dose)
Side Effects	Dry Mouth, ECG changes with electrolyte imbalances, Hypercalcemia, Hyperuricemia, Hypochloremia, Hyponatremia, Hypokalemia, Hypotension, Transient deafness, Tinnitus

GLUCAGON	
Class	Pancreatic Hormone, insulin antagonist.
Indications	Hypoglycemia (if D50 unavailable). Unconscious, combative, seizuring patients that an IV cannot be started and glucose is needed. Beta Blocker and Calcium Channel Blocker Overdose.
Contraindications	Hypersensitivity; pheochromocytoma, insulinoma
Dose & Route	Hypoglycemia: Adult: 1mg reconstituted IM/IV/SQ Q 15 min prn Peds: <20kg = 0.5mg, >20kg = 1mg IM/IV/SQ Q 15min prn Beta Blocker and Calcium Channel Blocker Overdose Adult: 3 to 10 mg IV bolus followed by an infusion of 3-5 mg/hr Peds: 0.15mg/kg IV bolus followed by an infusion of 0.07mg/kg/hr (Max 5mg/hr)
Side Effects	Hypotension, N/V, Tachycardia, Uticaria

IPATROPIUM (Atrovent)	
Class	Anticholinergic, Bronchodilator
Indications	Persistent bronchospasm associated with asthma and COPD.
Contraindications	Hypersensitivity to ipatropium, atropine, alkaloid, soybean products, or peanuts.
Dose & Route	Adult: 500mcg (0.5mg) in nebulizer typically with a beta adrenergic (Albuterol) Pediatrics: N/A
Side Effects	Anxiety. Blurred vision. Coughing. Dry mouth. Headache. Nausea/vomiting. Palpatations. Tachycardia.

KETOROLAC (Toradol)	
Class	NSAID
Indications	Short-term management of moderate to severe pain
Contraindications	Hypersensitivities to aspirin/NSAIDS, Active peptic ulcer disease, History of GI bleeding, Angioedema, Asthma, Renal Failure
Dose & Route	Adult: 30-60mg IM or 15-30 MG IVP Peds: Not recommended
Side Effects	Anaphylaxis, Bleeding disorders, Edema, Headache, Nausea, Sedation.

KETAMINE	
Class	Analgesic
Indications	Moderate to Severe acute and chronic pain, adjunct to aesthesia for procedures, or RSI
Contraindications	<3 months old, known or suspected schizophrenia (even if stable on current meds)
Dose & Route	Pain: Adult: IM: 2-4 mg/kg (repeat dose every 30 minutes to 1 hour as necessary to control severe pain or casualty develops nystagmus/rhythmic eye movement back and forth) IN: 0.5 to 1mg/kg (using nasal atomizer device) Q10min with 0.25-0.5mg/kg prn IV: 0.3mg/kg infused over 5 minutes Sedation: Adult and Peds: IM: 4-5 mg/kg, may repeat Q5-10 minutes prn IV: 1-2mg/kg over 1 min, may repeat 0.5-1mg/kg Q5-15 minutes prn
Side Effects	Delirium, confusion, dreamlike state, hallucinations, vivid imagery, Bradycardia, sialorrhea, nausea/vomiting, tachycardia, nystagmus, hypertension, hypertonia

LIDOCAINE 2%	
Class	Antidyrshythmic, local anesthetic
Indications	Significant ventricular ectopy in the setting of myocardial ischemia or infarction. Ventricular fibrillation. Ventricular Tachycardia.
Contraindications	2nd or 3rd degree heart block in absence of artificial pacemaker. Adams-stokes syndrome. WPW syndrome. PVC's in conjunction with bradycardia. Allergy to corn
Dose & Route	*Cardiac Arrest* (V-fib, Pulseless V-Tach): Adult: 1-1.5mg/kg IV/IO, repeat Q 5-10 minutes with 0.5-0.75mg/kg to a max of 3mg/kg May give 2-3.75mg/kg ET diluted in 5-10 ml NS or SWFI *Peds:* 1mg/kg IV/IO follow with infusion of 20- 50mcg/kg, May give 2-3 mg/kg/dose ET flushed with 5ml NS and 5 assisted manual ventilations *Maintenance infusion after conversion of rhythm:* Adult: Mix 2 grams in 500ml (4mg/ml) and infuse at 2-4mg/min. Peds: Dilute 120mg in 100ml and infuse at 20-50mcg/kg/min (1-2.5mg/kg/Hour)
Side Effects	Bradycardia, Blurred Vision, Cardiovascular collapse, CNS depression with high doses. Confusion. Hypotension. Lightheadedness.

LORAZEPAM (Ativan)	
Class	Benzodiazepine
Indications	Acute anxiety episodes, Combative patients, Difficult intubations, Muscle relaxant, Status epilepticus, Pre-medication for cardioversion or TCP.
Contraindications	Hypersensitivity. Respiratory depression. Acute narrow-angle glaucoma
Dose & Route	Adult: 2-4mg IV/IM Q5-10min (Max=4mg/dose) Pediatrics: 0.1 mg/kg IV/IM Q5-10min (Max=4mg/dose)
Side Effects	Decreased LOC. Hypotension. Respiratory depression.

MAGNESIUM SULFATE 10%	
Class	Electrolyte, Anti-Convulsant
Indications	Hypomagnesium, Pre-term labor, Seizures of ecclampsia, Torsades de Points, Refractory ventricular fibrillation.
Contraindications	Heart Block. Hypersensitivity. Hypocalacemia. Myocardial damage. Shock. Severe persistent hypertension
Dose & Route	*Seizure activity associated with pregnancy/pre-term labor:* 4-6 grams IV infused over 20 min, followed by 1-2grams/hour (Max=40g/24 hours) *Torsade/Refreactory VF,VT:* Adult: 1-2 grams IV/IO in 10 ML NS or D5W bolus if pulseless and over 15 Minutes with a pulse. Peds: 25-50mg/kg/dose IV/IO bolus if pulseless or over 20 minutes with pulse (Max=2grams/dose)
Side Effects	Bradycardia. Circulatory collapse. CNS Depression. Depressed reflex. Diaphoresis. Diarrhea. Flushing. Hypotension. Hypothermia. Respiratory depression

METHYLPREDNISOLONE (Solu-medrol)	
Class	Glucocorticoid (synthetic steroid)
Indications	Acute spinal cord injury. Anaphylaxis. Bronchodilator-unresponsive. Asthma. Shock (controversial)
Contraindications	None In emergency. Use in caution in GI bleeding, diabetes, and severe infection.
Dose & Route	Adult: 40-125mg IVP except for spinal injury which is 30mg/kg IV over 15 minutes followed by 5.4mg/kg/hour infusion. Peds: Spinal cord injury: same dose as adult Asthma Exacerbation: <12 years old; 1-2 mg/kg/day, Max=60mg/day >12 years old; Same as adult
Side Effects	Alkalosis, GI bleeding. Headache, Hypertension. Hypokalemia. Prolonged wound healing. Sodium and water retention.

MIDAZOLAM (Versed)	
Class	Benzodiazepine sedative/hypnotic
Indications	Premedication for cardioversion, RSI, Acute anxiety, status epilepticus.
Contraindications	Hypersensitivity. Acute narrow angle glaucoma.
Dose & Route	Sedation/anxiolysis Adult: IV: 2.5-5mg over 2 minutes, Q2-3min prn IM: 0.08 mg/kg IN: 0.1mg/kg Peds: IV: <6 months: Not recommended 6months-5 years: 0.05-0.1mg/kg (Max total dose= 6mg) 6-12 years old: 0.05mg/kg (Max total dose=10mg) >12 years old: Refer to Adult dosing (Max total dose=10mg) IM: 0.1-0.5mg/kg, Max total dose=10mg IN: 0.2-0.5mg/kg, Max total dose=10mg Status Epilepticus Adult: IV: 0.2mg/kg IM: 10mg once or 0.2mg/kg (Max 10mg/dose) Peds: IV: 0.2mg/kg IM: 0.2mg/kg (Max=10mg/dose)
Side Effects	AMS. Amnesia. Blurred Vision. Bradycardia. Cough. Drowsiness. Fluctuations in respiratory arrest. Respiratory depression. Tachycardia.

MORPHINE	
Class	Opioid analgesic
Indications	Chest Pain associated with MI. Moderate to Severe acute and chronic pain. Pulmonary edema with or without pain.
Contraindications	GI obstruction. Hypersensitivity. Hypotension. Hypovolemia. Patient having taken MAO inhibitors in last 14 days. Severe respiratory depression.
Dose & Route	Adult: Start 2-10mg SIVP (2mg/min) titrate to effect. Peds: 0.1-0.2mg/kg/dose SIVP Max dose: <1 year old= 2mg/dose, 1-6 years=4mg/dose, 7-12 years=8mg/dose, >12 years=10mg/dose
Side Effects	Allergic reaction, Altered mental status, Bradycardia, Bronchospasm, Dry Mouth, Euphoria, Flushing, Hypotension, Palpitations, Respiratory depression, Syncope, Tachycardia.

NALOXONE (Narcan)	
Class	Opioid antagonist
Indications	Coma of unknown origin, Decreased LOC, Known or suspected opioid overdose.
Contraindications	Hypersensitivity
Dose & Route	Adult: 0.4-2mg IV (preferred), IM, SC, and ET (2-2.5 times IV dose). Q 2 minutes (Max=10mg total) Peds: 0.1mg/kg IV (preferred), IM, SC, ET, or IO. (Max=2mg/dose) Q2 minutes
Side Effects	Blurred Vision, Diaphoresis, Dysrhythmias, Hypertension, N/V, Tachycardia, Withdrawal symptoms.

NITROGLYCERINE	
Class	Vasodilator, Antianginal agent, Extravasation antidote
Indications	AMI, CHF with pulmonary edema, Hypertensive emergencies, Ischemic chest pain, Pulmonary Hypertension.
Contraindications	Children under 12. Head injury with/without hemorrhage. Hypersensitivity to nitrates. Hypotension. Concurrent use with PDE-5 inhibitors. Corn allergy
Dose & Route	Adult: 0.3 or 0.6mg tablet or spray SL every 5 minutes to a total of 3 doses. IV Infusion: Mix 100-200mcg/ml drip and infuse at a rate of 5-20mcg/min to start. Increase at 5-10mcg/min every 5 minutes until desired effect is achieved or hypotension occurs. (Max=400mcg/min) Peds: N/A
Side Effects	Diaphoresis, Dizziness, Headache, Hypotension, N/V, Reflex tachycardia, syncope.

ONDANSETRON (ZOFRAN)	
Class	Antiemetic
Indications	Nausea & Vomiting
Contraindications	Hypersensitivity to dolasetron, granisetron. May precipitate with bicarb.
Dose & Route	Adult: 4-8mg IV/IO Slowly or IM. 8mg PO. Ped: 0.1mg/kg Slow IV/IO or IM. Max dose 4mg.
Side Effects	H/A, diarrhea, Fever, dizziness, pain, seizure, EPS, QT prolongation.

PROMETHAZINE (Phenegran)	
Class	Phenothiazine, Antihistamine, Antiemetic
Indications	Allergic Reactions, Motion Sickness, N/V, Pre/Post-Operative and obstetric sedation, potentiate analgesic effects
Contraindications	CNS depression from alcohol, barbiturates or narcotics. Comatose states, Hypersensitivity, Signs of Reye's Syndrome. Children <2 years old
Dose & Route	Adult: 12.5-25mg IVP/IM Peds: 0.5mg/kg IV/IM(Max=25mg/dose)
Side Effects	Tissue injury, Dizziness, Dysrhythmias, Dystonias, Hyperexcitability, Impairment of mental and physical ability, N/V, Sedation, Tachycardia / Bradycardia. Use in children may cause hallucinations, convulsions, and sudden death.

RACEMIC EPINEPHERINE	
Class	Sympathomimetic
Indications	Croup, laryngeal edema
Contraindications	Oral inhalation. Concurrent use or within 2 weeks of MAO inhibitors
Dose & Route	Adult: 0.5ml in 3-5ml saline nebulized Peds: 0.05-0.1 ML/kg in 3-5 salin nebulized (Max=0.5ml/dose)
Side Effects	Anxiety, HA, palpitations

ROCURONIUM	
Class	Neuromuscular blocker (non-depolarizing)
Indications	Adjunct to general anesthesia. Facilitation of endotracheal intubation. Maintenance of paralysis after intubation to assist ventilations.
Contraindications	Hypersensitivity
Dose & Route	Adult and Peds: 0.6-1.2 mg/kg IV
Side Effects	Apnea, Bradycardia, Hypo/Hypertension, Prolonged paralysis.

SODIUM BICARBONATE	
Class	Buffer, Alkalinizing agent, electrolyte supplement.
Indications	Alkalinization for treatment of specific intoxication's, Intubated patients with long arrest interval, PEA, Known or pre-existing bicarb responsive acidosis, Management of metabolic acidosis, Return circulation after long arrest interval, Tricyclic antidepressant OD. Hyperkalemia.
Contraindications	Abdominal pain of unknown origin, Hypocalcemia, Hypernatrenua, Alkalosis
Dose & Route	Adult: Cardiac Arrest: 1mEq/kg SIVP, repeat doses should be guided by arterial blood gases Hyperkalemia: 50meq IV over 5 minutes Peds: Cardiac Arrest/Hyperkalemia: (> two years of age) Same as Adult Infants: (< two years of age) 4.2% solution is recommended for IV administration Slow administration rates and the 4.2% solution are recommended in neonates, to guard against the possibility of producing hypernatremia, decreasing cerebrospinal fluid pressure, and inducing intracranial hemorrhage. Tricyclic Antidepressant Overdose: 1-2 mEq/kg IV boluses Q5-10min followed by an continuous infusion of 150meq/L solution to maintain alkalosis
Side Effects	Electrolyte Imbalance. Hypoxia, Metabolic alkalosis. Rise in intracellular PcO_2 and increased tissue acidosis. Seizures. Tissue sloughing at injection site.

SODIUM CHLORIDE	
Class	Isotonic IV fluid
Indications	Dehydration / Hypovolemia, Diabetic Ketoacidosis, Heat related emergency, Hypotension, Medication route.
Contraindications	CHF. Pulmonary edema. Severe electrolyte imbalance
Dose & Route	Adult: KVO for maintenance of drug route. 250-500 ml bolus for fluid resuscitation. Repeat as needed. Peds: 20ml/kg bolus repeat as needed.
Side Effects	Electrolyte imbalance. Pulmonary edema from overload.

SUCCINYLCHOLINE	
Class	Neuromuscular blocker (depolarizing)
Indications	Muscle relaxation. Terminate laryngospasm, facilitate intubation
Contraindications	Acute injuries, Acute rhabdomyolsis, Hypersensitivity, Inability to control airway or ventilate patient, Personal or family Hx of malignant hyperthermia, Skeletal muscle myopathies.
Dose & Route	Adult: 1-1.5mg/kg IVP over 10-30 seconds or 3 to 4 mg/kg IM Peds: Same as adult
Side Effects	Allergic Reaction, Bradycardia, Dysrhythmias, Excessive salivation, Hypotension, Initial muscle fasciculations, Malignant hyperthermia, May exacerbate hyperkalemia in trauma patients, Respiratory depression

THIAMINE	
Class	Vitamin B1
Indications	Beriberi. Delirium tremors. Wernicke's Encephalopathy.
Contraindications	None
Dose & Route	Adult: 100-250mg SIVP over 30 min for doses >100mg Peds: Rarely indicated
Side Effects	Allergic reactions (rare). Anxiety. Diaphoresis. Hypotension from rapid injection or large dose. N/V

VECURONIUM	
Class	Neuromuscular blocker (non-depolarizing)
Indications	Adjunct to anesthesia. Facilitation of endotracheal intubation. Maintenance of paralysis after intubation to assist ventilations.
Contraindications	Hypersensitivity to the drug or bromides.
Dose & Route	Adult and Peds: 0.1-0.2mg/kg IVP bolus
Side Effects	Apnea, Bradycardia, Hypotension, Prolonged paralysis.

IX. LABORATORY REFERENCE

(Mosby Paramedic (VOL. 7/2010 AHA updates))

HEMATOLOGY VALUES

*HCT (HEMATOCRIT) - *Measures relative volume of cells and plasma in blood. Low values suggest hemorrhage or anemia. High values suggest polycythemia or dehydration.*
Normal Adult Male Range 40 - 54%
Normal Adult Female Range: 37 - 47%
Normal Newborn Range: 50 - 62%

*HGB (HEMOGLOBIN) - *Measures Oxygen carrying capacity of blood. Low values suggest Hemorrhage or anemia, high values suggest polycythemia.*
Normal Adult Male Range: 14 - 18 g/dl
Normal Adult Female Range: 12 - 16 g/dl
Normal Newborn Range: 14 - 20 g/dl

*RBC (RED BLOOD CELL COUNT) - *Measures the number of red blood cells. RBCs transport hemoglobin, which carries oxygen. The amount of oxygen body tissues receive depends on the amount and function of RBCs and hemoglobin. RBCs normally survive about 120 days in the blood. They are then removed by specialized "clean-up" cells in the spleen and liver.*
Normal Adult Male Range: 4.2 - 5.6 mill/mcl
Normal Adult Female Range: 3.9 - 5.2 mill/mcl
Lower ranges are found in Children, newborns and infants

*WBC (WHITE BLOOD CELL COUNT) - *Measures defense against inflammatory agents. Low values suggest aplastic anemia, drug toxicity, specific infections. High values suggest inflammation, trauma, toxicity, leukemia.*
Normal Adult Range: 3.8 - 10.8 thous/mcl
Higher ranges are found in children, newborns and infants.

*PLATELET COUNT - *A platelet count is often ordered as a standard part of a complete blood count and is almost always ordered when a patient has unexplained bruises or takes what appears to be an unusually long time to stop bleeding from a small cut or wound.*
Normal Adult Range: 150 - 450 thous/mcl
Higher ranges are found in children, newborns and infants

ELECTROLYTE VALUES

*SODIUM - *Sodium is the most abundant cation in the blood and it's chief base. It functions in the body to maintain osmotic pressure, acid-base balance and to transmit nerve impulses.*
Normal Adult Range: 135-146 mEq/L

*POTASSIUM - *Potassium is the major intracellular cation.*
Normal Range: 3.5 - 5.5 mEq/L

*SODIUM/POTASSIUM
Normal Adult Range: 26 - 38 (calculated)

*CO2 (CARBON DIOXIDE) - *The CO_2 level is related to the respiratory exchange of carbon dioxide in the lungs and is part of the buffer system. Generally when used with the other electrolytes, it is a good indicator of acidosis and alkalinity.*
Normal Adult Range: 22-32 mEq/L
Normal Childrens Range - 20 - 28 mEq/L

IX. LABORATORY REFERENCE

*ANION GAP (SODIUM + POTASSIUM – CO_2 + CHLORIDE) - *An increased measurement is associated with metabolic acidosis due to the overproduction of acids. Decreased levels may indicate metabolic alkalosis due to the overproduction of alkaloids.* Normal Adult Range: 4 - 14 (calculated)

PROTEIN

*PROTEIN, TOTAL - *Decreased levels may be due to poor nutrition, liver disease, malabsorption, diarrhea, or severe burns. Increased levels are seen in lupus, liver disease, chronic infections, alcoholism, leukemia, tuberculosis amongst many others.*
Normal Adult Range: 6.0 -8.5 g/dl

*ALBUMIN - *Major constituent of serum protein (usually over 50%). High levels are seen in liver disease (rarely), shock, dehydration, or multiple myeloma. Lower levels are seen in poor diets, diarrhea, fever, infection, liver disease, inadequate iron intake, third-degree burns and edemas or hypocalcemia*
Normal Adult Range: 3.2 - 5.0 g/dl

HEPATIC ENZYMES

AST (SERUM GLUTAMIC-OXALOCETIC TRANSAMINASE - SGOT) - *Found primarily in the liver, heart, kidney, pancreas, and muscles. Seen in tissue damage - especially damage to the heart and liver.*
Normal Adult Range: 0 - 42 U/L

ALT (SERUM GLUTAMIC-PYRUVIC TRANSAMINASE - SGPT) - *Decreased SGPT in combination with increased cholesterol levels is seen in cases of a congested liver. Increased levels seen in mononucleosis, alcoholism, liver damage, kidney infection, chemical pollutants or myocardial infarction*
Normal Adult Range: 0 - 48 U/L

ALKALINE PHOSPHATASE - *Used as a tumor marker elevated levels seen in bone injuries, pregnancy, or skeletal growth. Low levels are sometimes found in hypoadrenia, protein and vitamin deficiency, and malnutrition.*
Normal Adult Range: 20 - 125 U/L
Normal Children's Range: 40 - 400 U/L

GGT (GAMMA-GLUTAMYL TRANSPEPTIDASE) - *Elevated levels seen with liver disease, alcoholism, bile-duct obstruction, cholangitis, drug abuse, and hypermagnesemia. Decreased levels can be found in hypothyroidism, hypothalamic malfunction and hypomagnesemia.*
Normal Adult Male Range: 0 - 65 U/L
Normal Adult Female Range: 0 - 45 U/L

LDH (LACTIC ACID DEHYDROGENASE) - *Increases are usually found in cellular death and/or leakage from the cell or in some cases it can be useful in confirming myocardial or pulmonary infarction (in conjunction with other tests). Decreased levels of the enzyme may indicate malnutrition, hypoglycemia, adrenal exhaustion or low tissue or organ activity.*
Normal Adult Range: 0 - 250 U/L

*BILIRUBIN, TOTAL - *Elevated in liver disease, mononucleosis, hemolytic anemia, low levels of exposure to the sun, and toxic effects to some drugs, decreased levels are seen in people with an inefficient liver, excessive fat digestion, and possibly a diet low in nitrogen bearing foods*
Normal Adult Range 0 - 1.3 mg/dl

IX. LABORATORY REFERENCE

RENAL RELATED

*B.U.N. (BLOOD UREA NITROGEN) - *Increases can be caused by excessive protein intake, kidney damage, certain drugs, low fluid intake, intestinal bleeding, and exercise or heart failure. Decreased levels may be due to a poor diet, malabsorption, liver damage or low nitrogen intake.*
Normal Adult Range: 7 - 25 mg/dl

*CREATININE - *Low levels are sometimes seen in kidney damage, protein starvation, liver disease or pregnancy. Elevated levels are sometimes seen in kidney disease due to the kidneys job of excreting creatinine, muscle degeneration, and some drugs involved in impairment of kidney function.*
Normal Adult Range: .7 - 1.4 mg/dl

*URIC ACID - *High levels are noted in gout, infections, kidney disease, alcoholism, high protein diets, and with toxemia in pregnancy. Low levels may indicate kidney disease, malabsorption, liver damage or an acidic kidney.*
Normal Adult Male Range: 3.5 - 7.5 mg/dl
Normal Adult Female Range: 2.5 - 7.5 mg/dl

*BUN/CREATININE - *This calculation is a good measurement of kidney and liver function.*
Normal Adult Range: 6 -25 (calculated)

CARDIAC

*CREATINE PHOSPHOKINASE (CK) - *Levels rise 4 to 8 hours after an acute MI, peaking at 16 to 30 hours and returning to baseline within 4 days*
25-200 U/L
32-150 U/L

*CK-MB CK ISOENZYME - *It begins to increase 6 to 10 hours after an acute MI, peaks in 24 hours, and remains elevated for up to 72 hours.*
< 12 IU/L if total CK is <400 IU/L
<3.5% of total CK if total CK is >400 IU/L

*(LDH) LACTATE DEHYDROGENASE - Total LDH will begin to rise 2 to 5 days after an MI; the elevation can last 10 days.
140-280 U/L

LDH-1 and LDH-2 (LDH ISOENZYMES) - *Compare LDH 1 and LDH 2 levels. Normally, the LDH-1 value will be less than the LDH-2. In the acute MI, however, the LDH 2 remains constant, while LDH 1 rises. When the LDH 1 is higher than LDH 2, the LDH is said to be flipped, which is highly suggestive of an MI. A flipped pattern appears 12-24 hours post MI and persists for 48 hours.*
LDH-1 18%-33%
LDH-2 28%-40%

*MYOGLOBIN - *Early and sensitive diagnosis of myocardial infarction in the emergency department This small heme protein becomes abnormal within 1 to 2 hours of necrosis, peaks in 4-8 hours, and drops to normal in about 12 hours.*
< 1

*TROPONIN COMPLEX - Peaks in 10-24 hours, begins to fall off after 1-2 weeks.
< 0.4

XI. Military Acute Concussion Evaluation (MACE) 2nd Edition

MACE 2
Military Acute Concussion Evaluation

Use MACE 2 as close to time of injury as possible.

Service Member Name: _____

DoDI/EDIPI/SSN: _____ Branch of Service & Unit: _____

Date of Injury: _____ Time of Injury: _____

Examiner: _____

Date of Evaluation: _____ Time of Evaluation: _____

Purpose: MACE 2 is a multimodal tool that assists providers in the assessment and diagnosis of concussion. The scoring, coding and steps to take after completion are found at the end of the MACE 2.

Timing: MACE 2 is most effective when used as close to the time of injury as possible. The MACE 2 may be repeated to evaluate recovery.

RED FLAGS

Evaluate for red flags in patients with Glasgow Coma Scale (GCS) 13-15.

- ❑ Deteriorating level of consciousness
- ❑ Double vision
- ❑ Increased restlessness, combative or agitated behavior
- ❑ Repeat vomiting
- ❑ Results from a structural brain injury detection device (if available)
- ❑ Seizures
- ❑ Weakness or tingling in arms or legs
- ❑ Severe or worsening headache

Defer MACE 2 if any red flags are present. Immediately consult higher level of care and consider urgent evacuation according to evacuation precedence/Tactical Combat Casualty Care (TCCC).

- ❑ **Negative for all red flags**
  Continue MACE 2, and observe for red flags throughout evaluation.

MACE 2 - Military Acute Concussion Evaluation

MILITARY ACUTE CONCUSSION SCREENING

Complete this section to determine if there was an injury event AND an alteration of consciousness or memory.

1. Description of Incident

A. Record the event as described by the service member or witness.

Use open-ended questions to get as much detail as possible.

_____

_____

_____

_____

Key questions:

- ❑ Can you tell me what you remember?
- ❑ What happened?
- ❑ Who were you last with?

B. Observable Signs

At the time of injury were any of these observable signs witnessed?
Visual clues that suggest a possible concussion include:

- ❑ Lying motionless on the ground
- ❑ Slow to get up after a direct or indirect blow to the head
- ❑ Disorientation, confusion, or an inability to respond appropriately to questions
- ❑ Blank or vacant look
- ❑ Balance difficulties, stumbling, or slow labored movements
- ❑ Facial injury after head trauma
- ❑ Negative for all observable signs

C. Record the type of event.

Check all that apply:

- ☐ Blunt object
- ☐ Sports injury
- ☐ Gunshot wound
- ☐ Fall
- ☐ Assault
- ☐ Explosion/blast Estimated distance ____
- ☐ Fragment
- ☐ Motor vehicle crash
- ☐ Other _____

D. Was there a blow or jolt to the head?

- ❑ Did your head hit any objects?
- ❑ Did any objects strike your head?
- ❑ Did you feel a blast wave? (A blast wave that is felt striking the body or head is considered a blow to the head.)
- ❑ Did you have a head acceleration or deceleration?

☐ **YES** ☐ **NO** ☐ **UNKNOWN**

Revised 10/2018 **dvbic.dcoe.mil** **Page 2 of 14**

MACE 2 - Military Acute Concussion Evaluation

2. Alteration of Consciousness or Memory

A. Was there alteration of consciousness (AOC)?
AOC is temporary confusion or "having your bell rung."

☐ YES ☐ NO

If yes, for how long? ____ seconds
____ minutes

☐ UNKNOWN

Key questions:
- ❑ Were you dazed, confused, or did you "see stars" immediately after the event?
- ❑ Did you feel like you were in a fog, slowed down, or "something was not right"?

B. Was there loss of consciousness (LOC)?
LOC is temporarily passing out or blacking out.

☐ YES ☐ NO

If yes, for how long? ____ seconds
____ minutes

☐ UNKNOWN

Key questions:
- ❑ Did you pass out or black out?
- ❑ Is there a period of time you cannot account for?

C. Was there any post traumatic amnesia (PTA)?
PTA is a problem remembering part or all of the injury events.

☐ YES ☐ NO

If yes, for how long? ____ seconds
____ minutes

☐ UNKNOWN

Key questions:
- ❑ Is there a period of time you cannot account for?
- ❑ What is the last thing you remember before the event?
- ❑ What is the first thing you remember after the event?

D. Was the AOC, LOC or PTA witnessed?

☐ YES ☐ NO

If yes, for how long? ____ seconds
____ minutes

☐ UNKNOWN

Tips for assessment:
- ❑ Ask witness to verify AOC, LOC or PTA and estimate duration.

3. Symptoms

Common symptoms after a concussion are listed below. For this event, check all that apply.

- ❑ Headache
- ❑ Dizziness
- ❑ Memory problems
- ❑ Balance problems
- ❑ Nausea/vomiting
- ❑ Difficulty concentrating
- ❑ Irritability
- ❑ Visual disturbances
- ❑ Ringing in the ears
- ❑ Other _____
- ❑ **Negative for all symptoms**

4. History

A. During the past 12 months, were you diagnosed with a concussion, not counting this event?

☐ YES ☐ NO

If yes, how many? ____

☐ UNKNOWN

B. History of diagnosed/treated headache disorder or migraine.

☐ YES ☐ NO

C. History of depression, anxiety, or other behavioral health concerns.

☐ YES ☐ NO

CONCUSSION SCREENING RESULTS (Possible Concussion?)

Was there a blow or jolt to the head (1D)
AND
ANY alteration of consciousness or memory? (2A, 2B, 2C, or 2D)

YES (to both) ⬇

POSITIVE CONCUSSION SCREEN:

1. **Continue** MACE 2.
2. Complete evaluation before prescribing rest.
3. Communicate findings to line leadership.
4. Document and code findings in electronic health record (EHR).

NO (to either or both) ⬇

NEGATIVE CONCUSSION SCREEN:

1. **Stop** MACE 2.
2. Initiate 24 hour-rest period, if deployed. During rest, avoid activities that worsen symptoms. Follow up with the service member after rest period per concussion management tool (CMT).
3. Communicate findings to line leadership.
4. Document and code findings in electronic health record (EHR).

COGNITIVE EXAM

5. Orientation

Score one point for each correct response.

Ask This Question	Incorrect	Correct
"What month is this?"	0	1
"What is the date or day of the month?"	0	1
"What day of the week is it?"	0	1
"What year is it?"	0	1
"What time do you think it is?"	0	1
Correct response must be within one hour of actual time.		

ORIENTATION TOTAL SCORE ____/5

6. Immediate Memory

Choose one list (A-F below) and use that list for the remainder of the MACE 2.

Read the script for each trial and then read all five words. Circle the response for each word for each trial. Repeat the trial three times, even if the service member scores perfectly on any of the trials.

Trial 1 script: Read the script exactly as written.

- *"I am going to test your memory. I will read you a list of words and when I am done, repeat back to me as many words as you can remember, in any order."*

Trials 2 and 3 script: Read the script exactly as written.

- *"I am going to repeat that list again. Repeat back to me as many words as you can remember, in any order, even if you said them before."*

	Trial 1		Trial 2		Trial 3	
List A	Incorrect	Correct	Incorrect	Correct	Incorrect	Correct
Jacket	0	1	0	1	0	1
Arrow	0	1	0	1	0	1
Pepper	0	1	0	1	0	1
Cotton	0	1	0	1	0	1
Movie	0	1	0	1	0	1

IMMEDIATE MEMORY TOTAL SCORE ____/15

Immediate Memory Alternate Word Lists

List B	List C	List D	List E	List F
Dollar	Finger	Baby	Candle	Elbow
Honey	Penny	Monkey	Paper	Apple
Mirror	Blanket	Perfume	Sugar	Carpet
Saddle	Lemon	Sunset	Sandwich	Saddle
Anchor	Insect	Iron	Wagon	Bubble

COGNITIVE EXAM - Continued

15. Concentration - Continued

B. Months in Reverse Order

Script: Read the script exactly as written.

- *"Now tell me the months of the year in reverse order. Start with the last month and go backward. So you'll say: December, November…Go ahead."*

Correct Response:
Dec – Nov – Oct – Sep – Aug – Jul – Jun – May – Apr – Mar – Feb – Jan

	Incorrect	Correct
ALL months in reverse order	0	1

MONTHS IN REVERSE ORDER (16B) ____/1

CONCENTRATION TOTAL SCORE ____/5
Sum of scores:
15A (0-4 points) and 15B (0 or 1 point)

16. Delayed Recall

Read the script and circle the response for each word.
Do NOT repeat the word list.
Note: Use the same list (A-F) that was used in Question 6.

Script: Read the script exactly as written.

- *"Do you remember that list of words I read a few minutes earlier? I want you to tell me as many words from that list as you can remember. You can say them in any order."*

List A	Incorrect	Correct
Jacket	0	1
Arrow	0	1
Pepper	0	1
Cotton	0	1
Movie	0	1

DELAYED RECALL TOTAL SCORE ____/5

Delayed Recall Alternate Word Lists

List B	List C	List D	List E	List F
Dollar	Finger	Baby	Candle	Elbow
Honey	Penny	Monkey	Paper	Apple
Mirror	Blanket	Perfume	Sugar	Carpet
Saddle	Lemon	Sunset	Sandwich	Saddle
Anchor	Insect	Iron	Wagon	Bubble

17. Vestibular/Ocular-Motor Screening (VOMS) for Concussion Instructions

VOMS Contraindication: Unstable Cervical Spine.

Consider defering VOMS if patient is overtly symptomatic or a trained provider unavailable. VOMS should be completed before return to duty. Use comment section for any provider-observed difficulty with specific VOMS tasks.

A. **Baseline symptoms.** Record headache, dizziness, nausea and fogginess (HDNF), on zero to 10 scale prior to screening.

B. **Smooth pursuits**. Service member and examiner are seated. Hold fingertip three feet from patient. Service member focuses on fingertip target as examiner moves fingertip smoothly horizontally one and a half feet right and left of midline at rate requiring two seconds to go fully from left to right and right to left. Perform twice. Repeat in vertical direction one and a half feet above and one and a half feet below midline up and down, moving eyes two seconds fully up and two seconds down. Perform twice. Record HDNF on a zero to 10 scale.

C. **Saccades**. Service member and examiner are seated.

1) **Horizontal saccades:** Hold two fingertips horizontally at a distance of three feet from service member, and one and a half feet left and right of midline so service member gazes 30 degrees left and right. Service member moves eyes as quickly as possible from point to point. Perform 10 times. Record HDNF on a zero to 10 scale.

2) **Vertical saccades:** Repeat with two fingertips vertically three feet from service member, and one and a half feet above and below midline so service member gazes 30 degrees upward and downward. Service member moves eyes as quickly as possible from point to point. Perform 10 times. Record HDNF on a zero to 10 scale.

D. **Convergence**. Service member and provider are seated facing each other. Service member focuses on font target (page 14) at arm's length and slowly brings toward tip of nose. Service member stops target when two distinct images seen or when outward deviation of eye observed. Repeat and measure three times. Record centimeters between target and tip of nose for each trial. A near point of convergence ≥ five centimeters from the tip of the nose is considered abnormal. Record HDNF on a zero to 10 scale.

17. Vestibular/Ocular-Motor Screening (VOMS) for Concussion Instructions (Continued)

E. Vestibular-ocular reflex (VOR) test. Service member and examiner are seated. Examiner holds font target (page 14) in front of service member in midline at three feet, rotation speed set with metronome.

1) **Horizontal VOR test:** Service member rotates head horizontally focusing on target at 20 degrees to each side. Rotation = 180 beats per minute (bpm). Perform 10 times. Record: HDNF 10 seconds after test.

2) **Vertical VOR test:** Repeat test moving head vertically 20 degrees up and down at 180 bpm. Perform 10 times. Record HDNF 10 seconds after test.

F .Visual motion sensitivity (VMS) test. Service member stands with feet shoulder width apart, facing a busy area. Examiner stands next to and slightly behind service member. Service member outstretches arm. Focusing on their thumb, the service member rotates head,eyes and trunk as unit 80 degrees right and left. Rotation = 50 bpm. Perform five times. Record HDNF on a zero to 10 scale.

17. VOMS Score Card

Vestibular/Ocular Motor Test:	Not Tested	Headache 0-10	Dizziness 0-10	Nausea 0-10	Fogginess 0-10	Comments
BASELINE SYMPTOMS:	N/A					
Smooth Pursuits						
Saccades – Horizontal						
Saccades – Vertical						
Convergence (Near Point)						(Near Point in cm): Measure 1: _____ Measure 2:_____ Measure 3:_____
VOR – Horizontal						
VOR – Vertical						
Visual Motion Sensitivity Test						
Total						

Any score above baseline is considered abnormal

VOMS RESULTS

☐ All Normal ☐ Any Abnormal

MACE 2 - Military Acute Concussion Evaluation

EXAM SUM-

Record the data for correct MACE 2 documentation.

Cognitive Summary

Orientation Total Score - Q5	/5
Immediate Memory Total Score (all 3 trials) **- Q6**	/15
Concentration Total Score (Sections A and B) **- Q15**	/5
Delayed Recall Total Score - Q16	/5
COGNITIVE RESULTS ≤ 25 is abnormal	/30

NEUROLOGICAL RESULTS (Q 7-14)	☐ Abnormal (+)	☐ Normal (-)
SYMPTOM RESULTS (Q 3)	☐ 1 or more symptoms (+)	☐ No symptoms (-)
HISTORY RESULTS (Q 4A-4C)	☐ Positive (+)	☐ Negative (-)

VOMS RESULTS (Q 17)	☐ Abnormal (+)	☐ Normal (-)	☐ Deferred
MACE 2 RESULTS		☐ Positive (+)	☐ Negative (-)

AFTER COMPLETING MACE 2:

- ❑ Document MACE 2 results in the EHR with coding instructions.
- ❑ Initiate 24-hour rest.
- ❑ Refer to concussion management tool for the management recommendations based on MACE 2 results.
- ❑ After 24-hour rest period, evaluate for initiation into the Progressive Return to Activity (PRA) following the guidance of the PRA Clinical Recommendation.

  Refer to Progressive Return to Activity Clinical Tool at dvbic.dcoe.mil/files/resources/2013_PRA_PCM_CST_FINAL.pdf

VOMS Equipment Sample 14 point font: **A**

TBI CODING INSTRUCTIONS

Initial TBI screening code*: Z13.850
TBI coding sequence:

1. **Primary TBI diagnostic code: S06. E L S E****
2. **Primary symptom code,** if applicable: (e.g., H53.2 - diplopia)
3. **Deployment status code,** if applicable:*** (e.g., Z56.82 for deployed or Z91.82 for history of military deployment)
4. **TBI external cause of morbidity code:** (For example, Y36.290A (A- use for initial visit) for war operations involving other explosions and fragments, military personnel, initial encounter)
5. Place of occurrence code, if applicable
6. **Activity code,** if applicable
7. **Personal History of TBI code:** if applicable Z87.820

* MACE 2
** Etiology, Location, Severity, Encounter
*** Deployment code must fall within the first four codes when applicable

For more information, see DVBIC ICD-10 Coding Guidance Tool.

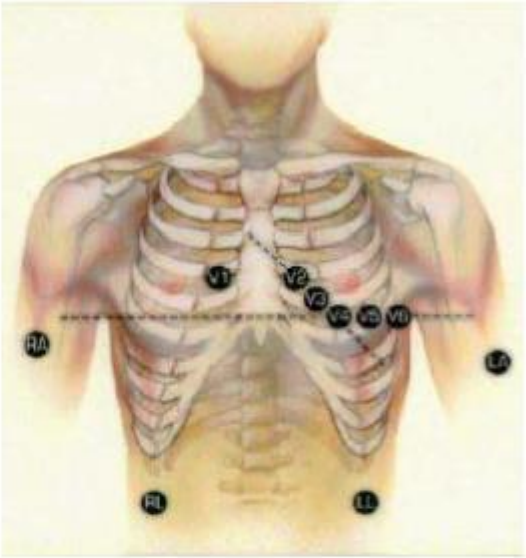
12-Lead ECG

INDICATIONS (EMT, A, I, P)

- Suspected cardiac patient
- Suspected overdose
- Electrical injuries
- Syncope/Near-Syncope
- CHF
- Nausea/Vomiting
- Chest Pain
- Shortness of Breath
- Abdominal Pain
- Upper back pain (non-muscular)
- Weakness
- Toxic exposures
- Atypical presentations



PROCEDURE

Standard

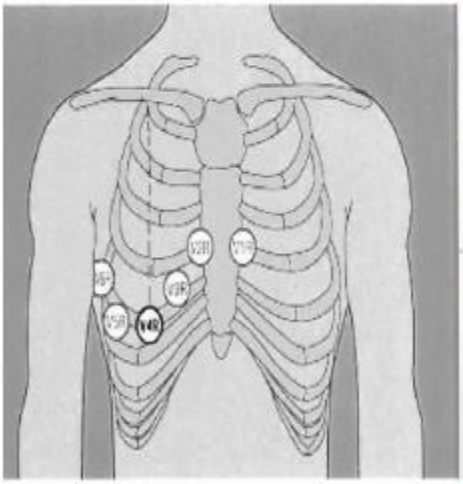
1. Prepare 12-Lead ECG monitor and connect patient cable with electrodes
2. Expose chest and prep as necessary. Modesty of the patient should be respected
3. Apply chest leads and extremity leads using the following landmarks:
    - RA- Right arm
    - LA- Left arm
    - RL- Right Leg
    - LL- Left Leg
    - V1- 4th intercostal space at right sternal border
    - V2- 4th intercostal space at left sternal border
    - V3- Directly between V2 and V4
    - V4- 5th intercostal space at midclavicular line
    - V5- Level with V4 at left anterior axillary line
    - V6- Level with V5 at left mid-axillary line
4. Instruct patient to remain still
5. Press the appropriate button to acquire the 12-Lead ECG within 5 minutes of patient contact

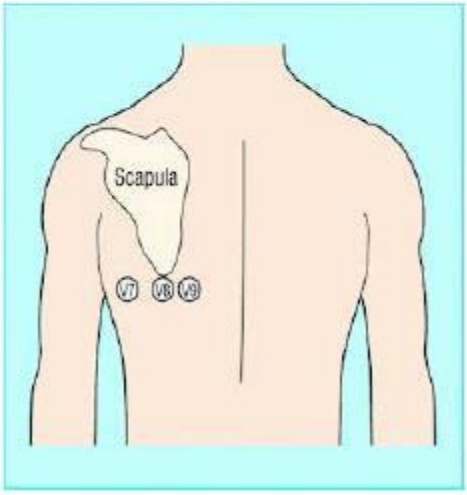
PROCEDURE FOR RIGHT-SIDED 12 LEAD

For Right-sided 12-Lead ECG (V4R) & Posterior 12-Lead ECG (V8 & V9), both together constitutes a 15-Lead ECG:

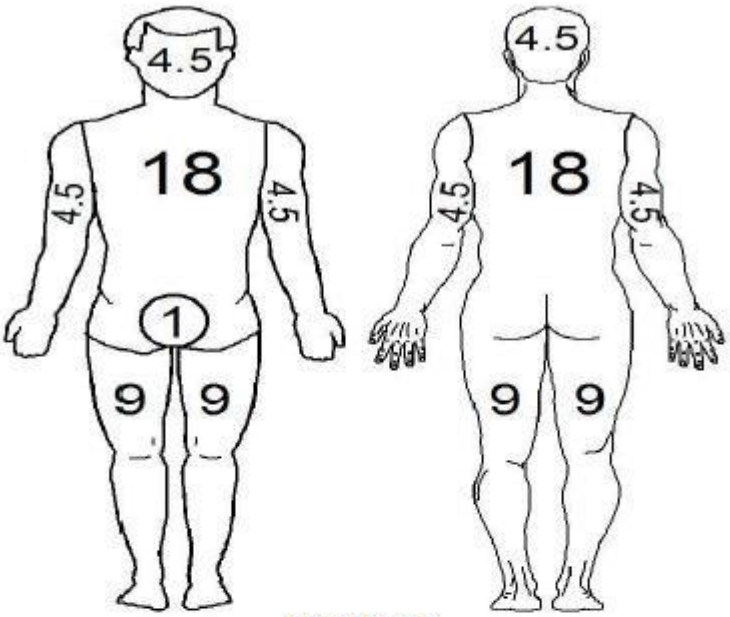
- V4R- (formerly V4) 5th intercostal space at midclavicular line on the patient's right side
- V8 - (formerly V5) 6th intercostal space left posterior at midscapular line
- V9 - (formerly V6) 6th intercostal space left at perispinal line
- Label the second 12-Lead ECG to reflect the new leads: V4 as V4R, V5 as V8, and V6 as V9

1. Print data as per guidelines and place the name and age of the patient on the paper copy of the 12-Lead ECG
2. STEMI suspected: notify and/or transmit to the closest Percutaneous Coronary Intervention (PCI) Center within 5 minutes
3. Document the procedure, time, and results on/with the patient care report (PCR)

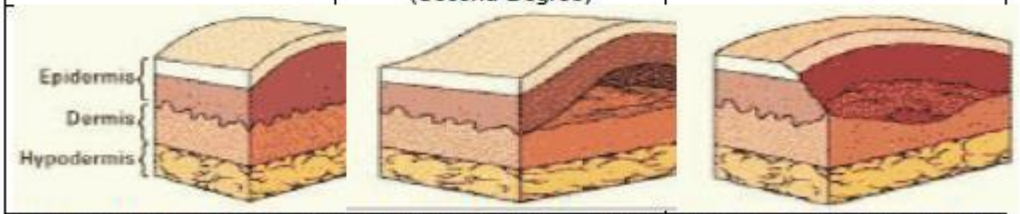




Adult Burn Chart/Reference



Palm Method:
The palm method is a tool whereby the size of the patients palm is used as an indicator for specific percentage of TBSA.
The surface area of a patients palm equals approximately 1% of TBSA.
This method is particularly useful where the burn has an irregular shape or has a scattered distribution.

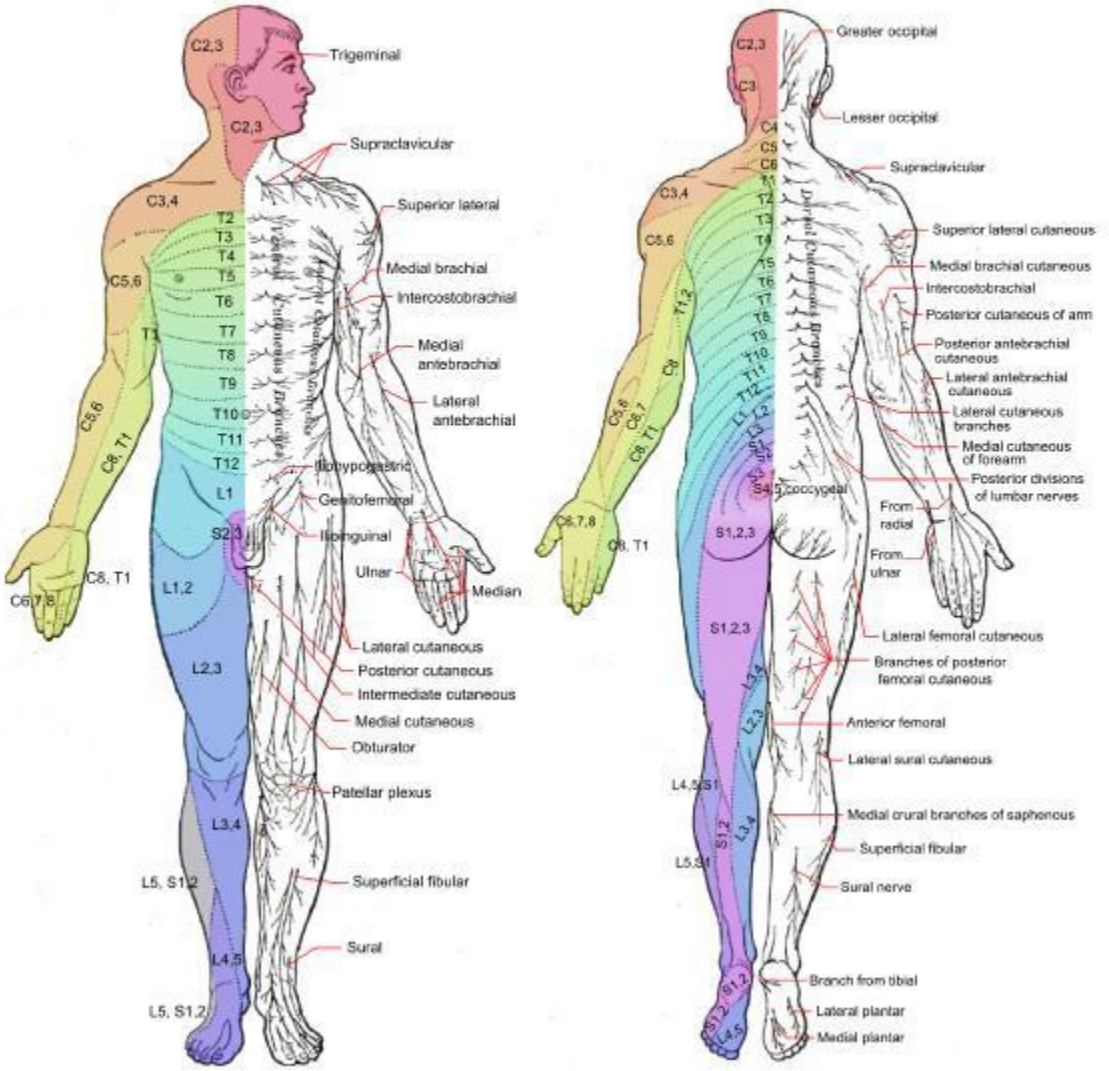
Superficial (First-Degree)	Partial Thickness (Second-Degree)	Full Thickness (Third-Degree)
		


Damage to the outer layer of skin {epidermis}, causing pain, redness and swelling.	Damage to both outer skin and underlying tissue layers {epidermis and dermis} causing pain, redness, swelling and blistering.	Damage extends deeper into tissues {epidermis, dermis and hypodermis} causing extensive tissue destruction. The skin may feel numb.

NERVE CHARTS

Dermatomes and Cutaneous Nerves

Schematic demarcation of dermatomes
There is considerable overlap between any two adjacent dermatomes



Drug	Dose (~80 kg)	per/kg	Duration	Description	Adverse Reactions
ketamine RSI	150mg	2mg/kg	15-30 min	Sleep dose for RSI	Hallucinations, ↑secretions
ketamine analgesia	20mg	0.1mg/kg	15-30 min	Analgesia	Hallucinations, ↑secretions
midazolam	5mg	0.05mg/kg	30 min	Sedation 5 mg, anxiety 2mg, sezures 5 mg (up to 10)	Airway obstruction, hypoventilation
diazepam	5-10mg	0.1mg/kg	60 min	Sedation 5mg, anxiety 2mg, antiepileptic 5 mg (up to 10)	Airway obstruction, hypoventilation
etomidate RSI	25mg	0.4mg/kg	15 min	Sleep dose for RSI	Apnea, maintains BP
propofol RSI	200mg	3mg/kg	15 min	Sleep dose for RSI	Apnea, hypotension
morphine	10mg	0.1mg/kg	60 min	Analgesia	Hypoventilation, apnea
fentanyl	50mcg	1mcg/kg	20 min	Analgesia	Hypoventilation, apnea
succinylcholine RSI	150mg	2mg/kg	10 min	Short acting paralytic	Apnea, hyperK$^+$, rhabdomyolysis
rocuronium	100mg	1mg/kg	30 min	Intermediate acting paralytic	Apnea
vecuronium	10mg	0.1mg/kg	45 min	Intermediate acting paralytic	Apnea
atropine	0.4mg	0.01mg/kg	30min	Treats bradycardia	Tachycardia, dilated pupils
naloxone	0.4mg	0.01mg//kg	20 min	Narcotic reversal	Increased pain
flumazenil	0.2mg	0.01mg/kg	20 min	Benzodiazepine reversal	Agitation
dexamethasone	4mg	0.1mg/kg	6 hours	Anaphylaxis, HACE, severe AMS	Hyperglycemia
mannitol	50Grams	1G/kg	4 hours	Extrication for crush injury	Dehydration
ondansetron	4mg	0.1mg/kg	4 hours	Antiemetic	Caution with long QT (torsades)
diphenhydramine	50mg	1mg/kg	4 hours	Antihistamine	Sedation (Benadryl)
promethazine	50mg	1mg/kg	6 hours	Antihistamine, antiemetic	Sedation (Phenergan)
dopamine	1 to 10 mcg/kg/min	----------	Infusion	↑cardiac contractility	Hypertension, ↑HR
dobutamine	2 to 20 mcg/kg/min	----------	Infusion	↑cardiac contractility	Hypertension, ↑HR
phenylephrine	0.15-0.75mcg/kg/min	----------	Infusion	↑systemic vascular resistance	Hypertension, renal failure
norepinephrine	0.05-0.5 mcg/kg/min	----------	Infusion	↑systemic vascular resistance	Hypertension, renal failure
vasopressin	0.01-0.035 **u**/kg/**HR**	----------	Infusion	↑SVR & renal blood flow	Hypertension
epinephrine 1:1,000	0.5mg(0.5ml) **SQ**	0.01mg/kg	1 hour	Tx anaphylaxis, bronchospasm	Skin necrosis in distal areas
Sed/hypnotic	Analgesic	Paralytic	Anticholinergics	Misc.	Pressors

Critical Care Quick Resource Sheet

Thoroughly mix the bag by inverting it twice. Inspect for any leaks or particulate.

Epinephrine Drip

To prepare an epinephrine drip solution:
Add 1 mg of Epinephrine to a 250mL bag of Normal Saline (NS)
1 mg of Epinephrine is:
1mL of Epinephrine 1:1000 or 10mL of Epinephrine 1:10,000

For 4 mcg/mL

	2 mcg/ min	3 mcg/ min	4 mcg/ min	5 mcg/ min	6 mcg/ min	7 mcg/ min	8 mcg/ min	9 mcg/ min	10 mcg/ min
Epinephrine Dose	These are all drops per minute utilizing a mini-drip set (60 drop set)								
Drops per 60 seconds	30	45	60	75	90	105	120	135	150
Drops per 15 seconds	8	11	15	19	23	26	30	34	38

Levophed (Norepinephrine) to Treat Post-Arrest Hypotension Chart
Add 4 mg of Levophed (Norepinephrine) to 250 ml Normal Saline
These are all drops per minute utilizing a mini-drip set (60 drop set)

Dosage using estimated body weight	gtts by Time	0.1 mcg/kg/ min	0.2 mcg/kg/ min	0.3 mcg/kg/ min	0.4 mcg/kg/ min	0.5 mcg/kg/ min
Small Adult (100 lbs/ 45Kg)	1 minute	17 gtts	34 gtts	51 gtts	68 gtts	85 gtts
	15 seconds	4 gtts	9 gtts	13 gtts	17 gtts	21 gtts
Medium Adult (150 lbs/ 68Kg)	1 minute	26 gtts	51 gtts	77 gtts	102 gtts	128 gtts
	15 seconds	7 gtts	13 gtts	19 gtts	26 gtts	32 gtts
Large Adult (200 lbs/ 91Kg)	1 minute	34 gtts	68 gtts	102 gtts	136 gtts	170 gtts
	15 seconds	9 gtts	17 gtts	26 gtts	34 gtts	43 gtts
Extra-Large Adult (250 lbs/ 113 Kg)	1 minute	43 gtts	85 gtts	128 gtts	170 gtts	213 gtts
	15 seconds	11 gtts	21 gtts	32 gtts	43 gtts	53 gtts
Obese Adult (>300 lbs/ 136 Kg)	1 minute	51 gtts	102 gtts	153 gtts	204 gtts	255 gtts
	15 seconds	13 gtts	26 gtts	38 gtts	51 gtts	64 gtts

The infusion should be titrated to achieve a systolic blood pressure between 90-100 mmHg.

$EtCO_2$ Quick Reference

Capnography

INDICATIONS

- Altered mental status
- Cardiac arrest with return of spontaneous circulation (ROSC)
- Any serious trauma or medical condition
- Any use of Naloxone (Narcan)

CONTRAINDICATIONS

None

PROCEDURE

Follow manufacturer's instructions for placement and use of device.
Use on both adult and pediatric patients.
Endotracheal tube (ETT)/blind insertion airway device (BIAD)/bag valve mask (BVM): • Turn on recording instrumentation. • Place $ETCO_2$ sampling device in between ventilation device (BVM/ventilator) and the mask/endotracheal tube (ETT)/King Airway/Combitube/ Laryngeal Mask Airway (LMA) • Attach sampling device to recording instrumentation and ventilate. • The Capnometer shall remain in place with the airway and be monitored throughout
Non-intubated spontaneously breathing patient: • Turn on recording instrumentation. • Place the sampling nasal cannula on the patient. • Attach sampling device to recording instrumentation. Observe and record results. • The capnometer shall remain in place with the airway and be monitored throughout prehospital care and transport.
Continuous positive airway pressure (CPAP)/ Bilevel positive airway pressure (BiPAP): • Follow manufacturer's recommendations for placement of $ETCO_2$ in conjunction with use of CPAP/BIPAP. • Place sampling nasal cannula on the patient. • Place CPAP/ BiPAP mask on patient ensuring a good seal. • Observe and record results. • The capnometer shall remain in place with the airway and be monitored throughout prehospital care and transport.

PEARLS

Normal range → $ETCO_2$ in adult and pediatric patients is 35-45 mm Hg. Cardiac arrest → Attempt to keep $ETCO_2$ above 10 mm Hg.

Post-cardiac arrest → Attempt to keep $ETCO_2$ between 34-40 mm Hg.

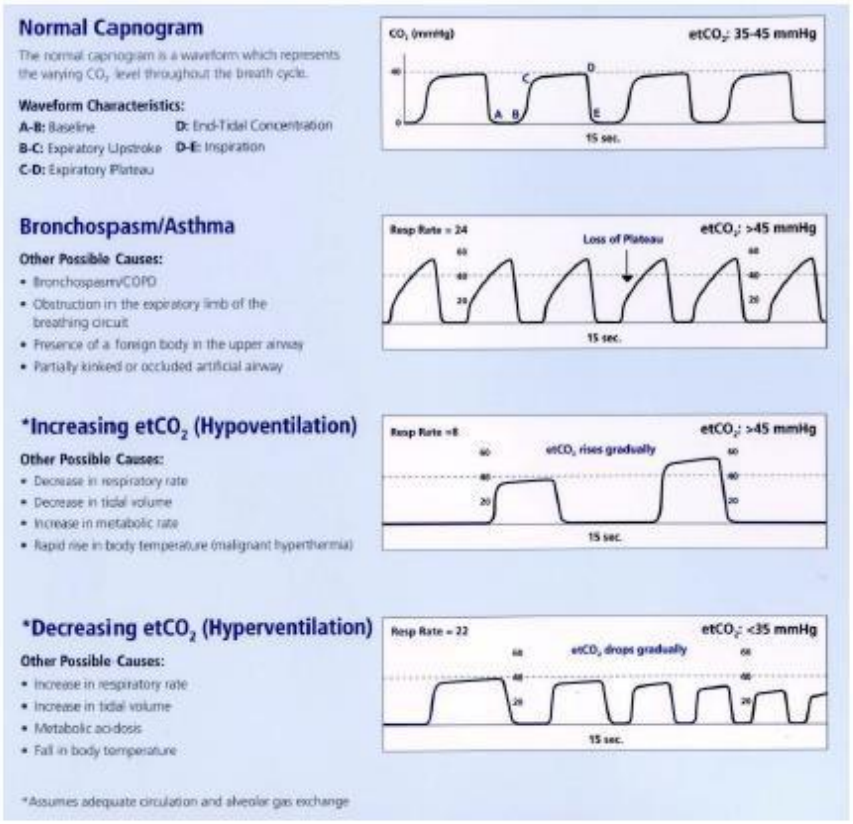
$EtCO_2$ Quick Reference

If $ETCO_2$ levels remain above 45 mm Hg despite ventilatory assistance, bronchodilators, CPAP or BIPAP, intubation may be needed.

When $ETCO_2$ is not detected, three factors must be addressed:

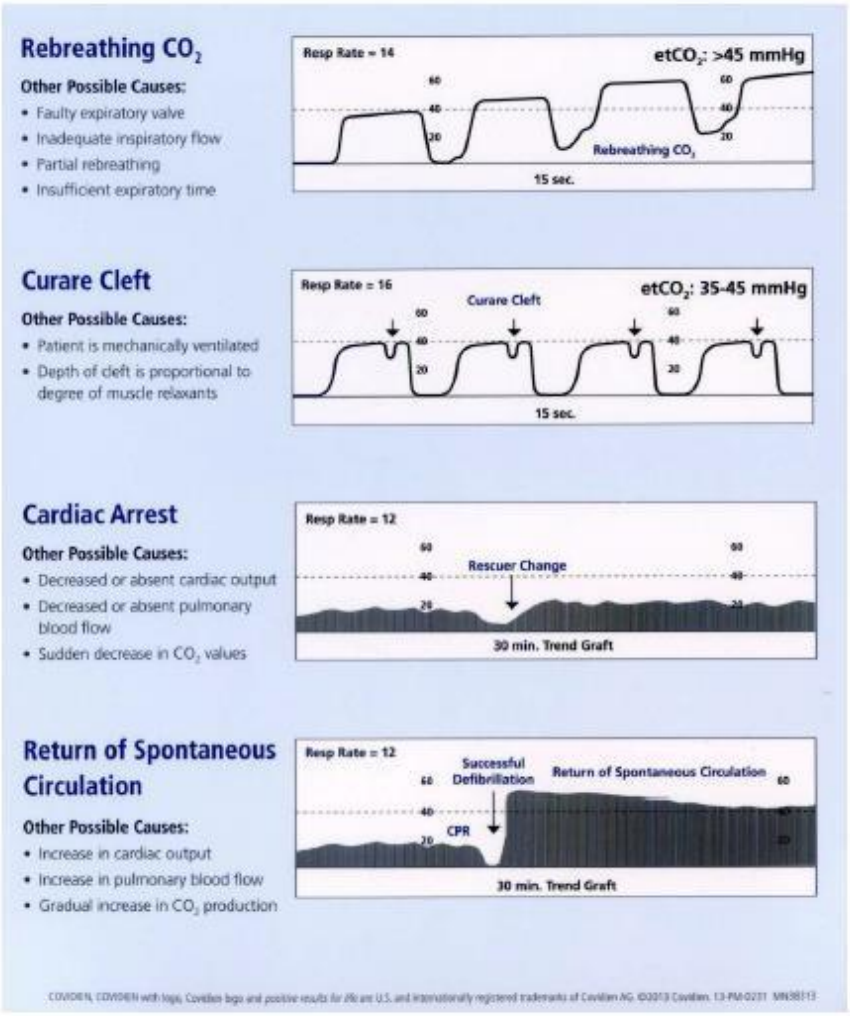
- Loss of airway/apnea → Esophageal ETT placement or migration
- Circulatory collapse → Cardiac arrest, pulmonary embolism, hypoperfusion
- Equipment failure → Disconnected BVM or ventilator, obstruction in $ETCO_2$ detector or sampling tube

Normal and Abnormal $etCO_2$/Capnograph Waveforms



Normal Capnogram
The normal capnogram is a waveform which represents the varying CO_2 level throughout the breath cycle.
Waveform Characteristics:
A-B: Baseline
B-C: Expiratory Upstroke
C-D: Expiratory Plateau
D: End-Tidal Concentration
D-E: Inspiration
CO_2 (mmHg)
$etCO_2$: 35-45 mmHg
A B C D E
15 sec.
Bronchospasm/Asthma
Other Possible Causes:
• Bronchospasm/COPD
• Obstruction in the expiratory limb of the breathing circuit
• Presence of a foreign body in the upper airway
• Partially kinked or occluded artificial airway
Resp Rate = 24
Loss of Plateau
$etCO_2$: >45 mmHg
15 sec.
*Increasing $etCO_2$ (Hypoventilation)
Other Possible Causes:
• Decrease in respiratory rate
• Decrease in tidal volume
• Increase in metabolic rate
• Rapid rise in body temperature (malignant hyperthermia)
Resp Rate =8
$etCO_2$ rises gradually
$etCO_2$: >45 mmHg
15 sec.
*Decreasing $etCO_2$ (Hyperventilation)
Other Possible Causes:
• Increase in respiratory rate
• Increase in tidal volume
• Metabolic acidosis
• Fall in body temperature
Resp Rate = 22
$etCO_2$ drops gradually
$etCO_2$: <35 mmHg
15 sec.
*Assumes adequate circulation and alveolar gas exchange

$EtCO_2$ Quick Reference



Useful Mnemonics

Causes of Coma/Decreased Level of Consciousness
A - Alcohol (and other drugs), Acidosis (hyperglycemic coma/DKA)
E - Electrolyte abnormality, Endocrine problem, Epilepsy
I - Insulin (diabetes/hypoglycemic shock)
O - Oxygen (Hypoxia), Overdose (or poisoning)
U - Uremia (renal failure/insufficiency)
T - Trauma; Temperature (hypothermia, heat stroke)
I - Infection (e.g., meningitis, encephalitis, sepsis)
P - Psychogenic ("hysterical coma")
S - Stroke or Space-occupying lesions in the cranium; Seizure; Shock

Coma Assessment
D - Depth of coma (responds to verbal or painful stimulus, unresponsive)
E - Eyes (PERRLA)
R - Respiration (rate and rhythm)
M - Motor (posturing; loss of movement/sensation)

Level of Consciousness
A - Alert
V - Responds to Verbal stimuli
P - Responds to Painful stimuli
U – Unresponsive

Patient History / Pain Assessment
A - Allergies
M - Medications
P - Past medical history (illness, injury)
P - Pain (PPQRST)
L - Last intake (food, fluid)
E - Ever happen before?
P - Pain (sharp or dull)
P - Palliative &/or Precipitating (exacerbating) measures related to the pain
Q - Quality (diffuse, pinpoint, or localized)
R - Radiating
S - Severity (scale of 1-10)
T - Timing: Time of onset; frequency; duration

Pupil Reaction
P - Pupils
E - Equal
R - Round
R - Reactive to
L - Light

Dive Related Accidents
V - Visual (Tunnel vision or blurred vision)
E - Ear symptoms (Tinnitus)
N - Nausea and/or vomiting
T - Twitching (Generally involves facial muscles, but can involve arms/legs)
L - Irritability (Change in diver's mental status)
D - Disability (Sudden neurological deficit)

Patient Care
V - Vitals
O – Oxygen
M – Monitor / Medications
I – IV/IO
T - Transport

XII. MEDICATIONS AND THEIR USES

Trade names start with an uppercase letter and appear in **blue**.
Generic names start with a lowercase letter and appear in **red**.
The primary type of medical problem for which the medication is used is listed, and the type of medication is shown in parentheses, when indicated.

Abilify Bipolar disorder, schizophrenia
Accolate Asthma
Accupril High blood pressure, congestive heart failure
acetaminophen with codeine Pain
Aciphex Gastric problems (antiulcer)
Actiq Pain (narcotic analgesic)
Actonel Osteoporosis
Actos Diabetes (oral antidiabetic)
acyclovir Viral infections (antiviral)
Adderall Attention deficit/hyperactivity disorder
Adipex Weight loss
Advair Breathing problems
albuterol Breathing problems (bronchodilator)
Aldactazide High blood pressure (diuretic/water pill)
Aldactone Congestive heart failure (diuretic/water pill)
Aldomet High blood pressure
alendronate Osteoporosis
Alesse 28 Birth control pills
Allegra Allergies (antihistamine)
Alli Weight loss
allopurinol Gout, kidney stones
alprazolam Anxiety, depression (sedative/antianxiety)
Altace High blood pressure (ACE inhibitor)
Alupent Asthma, breathing problems (bronchodilator)
Amaryl Diabetes (oral antidiabetic)
Ambien Insomnia (hypnotic)
Amitiza Gastrointestinal problems
amitriptyline Depression (antidepressant)
amlodipine High blood pressure, angina
amoxicillin Infection (antibiotic)
Amoxil Infection (antibiotic)
Anaprox Arthritis (anti-inflammatory)
Ansaid Arthritis (anti-inflammatory)
Antivert Dizziness, motion sickness (antivertigo)
Apresoline High blood pressure (antihypertensive)
Aricept Alzheimer's disease
Artane Parkinson's disease (anti-Parkinson)
Arthrotec Arthritis (anti-inflammatory)
Asacol Ulcerative colitis (antibacterial)
Asmanex Asthma (anti-inflammatory)
Aspirin Analgesic
Atarax Anxiety, behavioral disorders (sedative)
atenolol High blood pressure, heart problems, angina (beta blocker)
Ativan Anxiety (sedative/antianxiety)
Atrovent Breathing problems (bronchodilator)

Augmentin Infection (antibiotic)

Avandamet Diabetes
Avandia Diabetes (oral antidiabetic)
Avapro High blood pressure
Avodart Prostate enlargement
Axid Ulcers (antiulcer)
azithromycin Infection (antibiotic)
Azulfidine Ulcerative colitis (antibacterial)
Bactrim Infection (antibiotic)
Bactroban Impetigo (antibiotic)
Benadryl Allergies (antihistamine)
benazepril High blood pressure, congestive heart failure
Benicar High blood pressure
Bentyl Irritable bowel syndrome (anticholinergic)
benzonatate Cough (antitussive)
Biaxin Infection (antibiotic)
bisoprolol High blood pressure (diuretic)
Boniva Osteoporosis
Brethine Asthma, breathing problems (bronchodilator)
Bumex Edema, congestive heart failure (diuretic)
bupropion Depression, smoking cessation
BuSpar Anxiety (antianxiety)
buspirone Anxiety (antianxiety)
Byetta Diabetes
Caduet High blood pressure
Calan Angina, high blood pressure, rapid heart rate
Capoten High blood pressure, congestive heart failure
captopril High blood pressure, congestive heart failure
Carafate Ulcers (antiulcer)
carbamazepine Seizure disorder (anticonvulsant)
Cardizem Heart problems, angina (coronary vasodilator)
Cardura High blood pressure (alpha blocker)
carisoprodol Muscle spasms (muscle relaxant)
Cartia Angina, heart problems (calcium-channel blocker)
carvedilol High blood pressure
Catapres High blood pressure (antihypertensive)
Ceclor Infection (antibiotic)
cefaclor Infection (antibiotic)
cefdinir Infection (antibiotic)
cefixime Infection (antibiotic)
cefprozil Infection (antibiotic)
Ceftin Infection (antibiotic)
cefuroxime Infection (antibiotic)
Cefzil Infection (antibiotic)
Celebrex Arthritis (anti-inflammatory)
Celexa Depression (antidepressant)
cephalexin Infection (antibiotic)
cetirizine Antihistamine
Chantix Smoking cessation
Cialis Male impotence
Ciloxin Infection (antibiotic)
cimetidine Ulcers, gastric problems (antiulcer)

Cipro Infection (antibiotic)
citalopram Depression

Clarinex Allergies (antihistamine)
Claritin Allergies (antihistamine)
clarithromycin Infection (antibiotic)
clindamycin Infection (antibiotic)
Clinoril Arthritis pain (anti-inflammatory)
clonazepam Seizure disorder (anticonvulsant)
clonidine High blood pressure (antihypertensive)
clopidogrel Antiplatelet
clotrimazole Fungal infection (antifungal)
Colestid High cholesterol (cholesterol-lowering agent)
Combivent Breathing problems (bronchodilator)
Compazine Nausea (antiemetic)
Concerta Attention deficit/hyperactivity disorder
Coreg High blood pressure, heart problems
Corgard Heart problems, angina (beta blocker)
Cotrim Infection (anti-infective)
Coumadin Blood clots (blood thinner)
Cozaar High blood pressure
Crestor High cholesterol
cyclobenzaprine Muscle spasms (muscle relaxant)
Cymbalta Depression
Darvocet-N Pain management (narcotic analgesic)
Daypro Arthritis (anti-inflammatory)
Deltasone Severe inflammation (anti-inflammatory)
Demadex Edema, congestive heart failure (diuretic)
Demerol Pain (narcotic analgesic)
Depakote Seizure disorder (anticonvulsant)
Desyrel Depression (antidepressant)
Detrol Overactive bladder
Dexedrine Narcolepsy, attention-deficit disorder
dexmethylphenidate Attention deficit/hyperactivity disorder
DiaBeta Diabetes (oral antidiabetic)
Diabinese Diabetes (oral antidiabetic)
diazepam Anxiety (antianxiety)
diclofenac Inflammation (anti-inflammatory)
Diflucan Fungal infection (antifungal)
Digitek Heart problems
digoxin Heart problems
Dilantin Seizure disorder (anticonvulsant)
diltiazem Heart problems, angina (coronary vasodilator)
Diovan High blood pressure (antihypertensive)
Dipentum Ulcerative colitis
diphenhydramine Allergies (antihistamine)
dipyridamole Thromboembolism
Ditropan Bladder problems (antispasmodic)
Donnatal Irritable bowel syndrome (anticholinergic)
doxazosin Hypertension, prostate problems
doxycycline Infection (antibiotic)
Duricef Infection (antibiotic)
Dyazide High blood pressure, edema (diuretic)

DynaCirc High blood pressure
E.E.S. Infection (antibiotic)
Effexor Depression (antidepressant)
Elavil Depression (antidepressant)
Eldepryl Parkinson's disease (anti-Parkinson)
Elocon Dermatologic problems
Emend Nausea (antiemetic)
enalapril High blood pressure, heart failure
Enbrel Rheumatoid arthritis
E-Mycin Infection (antibiotic)
Entex Cough and congestion (expectorant)
epinephrine Cardiac arrest, allergic reactions
Epivir Antiretroviral
Ery-Tab Infection (antibiotic)
erythromycin Infection (antibiotic)
escitalopram Depression
Esidrix High blood pressure (diuretic/water pill)
Eskalith Behavioral disorders (antimanic)
Estrace Estrogen therapy
Estraderm Estrogen therapy
estradiol Menopause, gynecologic problems
etodolac Arthritis, pain (anti-inflammatory)
Evista Osteoporosis
famotidine Ulcers, gastric problems (antiulcer)
Feldene Arthritis (anti-inflammatory)
fentanyl Pain management (narcotic analgesic)
finasteride Prostate enlargement
Fiorinal Pain management (non-narcotic analgesic)
Flagyl Infections (antibacterial)
Flexeril Muscle spasms (muscle relaxant)
flexofenadine Antihistamine
Flomax Enlarged prostate (alpha blocker)
Flonase Allergies
Flovent Breathing problems
Floxin Infection (antibiotic)
fluconazole Fungal infection
fluoxetine Depression (antidepressant)
flurbiprofen Inflammation (anti-inflammatory)
folic acid Anemia
Fosamax Osteoporosis
fosinopril Osteoporosis
furosemide Congestive heart failure (diuretic/water pill)
gabapentin Seizures
Gabitril Seizure disorder (antiseizure)
Gantrisin Infection (antibiotic)
gemfibrozil High cholesterol (cholesterol-lowering agent)
Geodon Antipsychotic
glimepiride Diabetes (hyperglycemia)
glipizide Diabetes (oral antidiabetic)
Glucophage Diabetes (oral antidiabetic)
Glucotrol Diabetes (oral antidiabetic)
Glucovance Diabetes (oral antidiabetic)
glyburide Diabetes (oral hypoglycemic)

Glycolax Constipation
granisetron Nausea
guaifenesin Cough and congestion (expectorant)
Halcion Insomnia (hypnotic/sedative)
Haldol Psychotic disorders (antipsychotic)
HCTZ High blood pressure (diuretic/water pill)
Humira Rheumatoid arthritis
Humulin Diabetes (insulin)
hydrochlorothiazide High blood pressure (diuretic)
hydrocodone Cough, pain (narcotic)
HydroDiuril High blood pressure (diuretic/water pill)
hydroxyzine Anxiety, behavioral disorders (sedative)
Hygroton High blood pressure (diuretic/water pill)
Hytrin High blood pressure (alpha blocker)
Hyzaar High blood pressure (antihypertensive)
ibuprofen Inflammation, pain, fever (anti-inflammatory)
Imdur Heart problems, angina (coronary vasodilator)
Imitrex Migraine headaches (antimigraine)
Inderal High blood pressure, heart problems, angina (beta blocker)
Indocin Osteoarthritis, pain (anti-inflammatory)
indomethacin Arthritis (anti-inflammatory)
Intal Asthma (mast cell stabilizer)
Iophen Cough (antitussive)
Isoptin Angina, high blood pressure, rapid heart rate
Isordil Heart problems, angina (coronary vasodilator)
isosorbide dinitrate Heart problems, angina (coronary vasodilator)
K-Dur Potassium replacement, taken with diuretics
K-Tab Potassium replacement, taken with diuretics
Keflex Infection (antibiotic)
Keppra Seizure disorder (anticonvulsant)
ketoconazole Fungal infection (antifungal)
ketorolac Pain management (anti-inflammatory)
Klonopin Seizure disorder (anticonvulsant)
labetalol High blood pressure (beta blocker)
Lamictal Seizure disorder (anti-epileptic)
Lamisil Antifungal
Lanoxin Heart problems
Lasix Congestive heart failure (diuretic/water pill)
Lescol High cholesterol (cholesterol-lowering agent)
Levaquin Infection (antibiotic)
Levitra Male impotence
Levothroid Thyroid disease (thyroid hormone)
levothyroxine Thyroid problems (thyroid hormone)
Levoxyl Thyroid disease (thyroid hormone)
Lexapro Depression
Librax Peptic ulcer (anticholinergic)
Lipitor High cholesterol (cholesterol-lowering agent)
lisinopril High blood pressure
lithium carbonate Behavioral disorders (antipsychotic)
Lodine Arthritis, pain (anti-inflammatory)
Loestrin Fe Birth control pills
Lomotil Diarrhea (antidiarrheal)
Lopid High cholesterol (cholesterol-lowering agent)

Lopressor High blood pressure (beta blocker)
Lorabid Infection (antibiotic)
loracarbef Infection (antibiotic)
loratadine Allergies (antihistamine)
lorazepam Anxiety (sedative/antianxiety)
Lorcet Pain (narcotic analgesic)
Lortab Pain (narcotic analgesic)
Lotensin High blood pressure (ACE inhibitor)
Lotrel Hypertension
Lotrimin Fungal infection (antifungal cream and ointment)
Lotrisone Fungal infection (antifungal cream)
lovastatin High cholesterol (cholesterol-lowering agent)
Lozol Congestive heart failure, high blood pressure
Lunesta Sleep aid
Luvox Parkinson's disease (anti-Parkinson)
Lyrica Nerve pain
Macrobid Urinary tract infection (antibiotic)
Macrodantin Urinary tract infection (antibiotic)
marijuana Comfort management
Maxzide High blood pressure (diuretic/water pill)
meclizine Dizziness, vertigo, motion sickness (antiemetic)
medroxyprogesterone Gynecologic problems
meloxicam Inflammation, pain
metformin Diabetes
methadone Pain (narcotic analgesic), opiate withdrawal
methylphenidate Attention deficit disorder, narcolepsy
methylprednisolone Anti-inflammatory
metoclopromide Gastric problems (antiemetic)
metoprolol tartrate High blood pressure, heart problems (beta blocker)
metronidazole Infection (anti-infective)
Mevacor High cholesterol (cholesterol-lowering agent)
Micro-K Potassium replacement, taken with diuretics
Micronase Diabetes (oral antidiabetic)
Minipress High blood pressure (antihypertensive)
Minocin Infection (antibiotic)
minocycline Infection (antibiotic)
Miralax Constipation
Mirapex Parkinson's disease (anti-Parkinson)
Mircette Birth control pills
mirtazapine Anxiety, depression
Mobic Inflammation, pain
moexipril High blood pressure
Monopril High blood pressure
morphine Pain management (narcotic analgesic)
Motrin Inflammation, pain, fever (anti-inflammatory)
nabumetone Inflammation, pain (anti-inflammatory)
Namenda Alzheimer's disease
Naprosyn Inflammation, pain (anti-inflammatory)
naproxen Inflammation, pain (anti-inflammatory)
Nasacort Asthma, breathing problems (anti-inflammatory)
Nasonex Allergies (anti-inflammatory)
Necon Birth control pills
Neurontin Seizure disorders (anticonvulsant)

Nexium Gastric problems
Niaspan High cholesterol
nifedipine Heart problems, angina (coronary vasodilator)
Nitro-Dur Heart problems, angina (coronary vasodilator)
nitrofurantoin Urinary tract infection
nitroglycerin Heart problems, angina (coronary vasodilator)
Nitrostat Heart problems, angina (coronary vasodilator)
nizatidine Ulcers (antiulcer)
Nizoral Fungal infection (antifungal)
Norco Pain (narcotic analgesic)
Normodyne High blood pressure
nortriptyline Depression (antidepressant)
Norvasc High blood pressure (calcium-channel blocker)
nystatin Fungal infection (antifungal)
omeprazole Ulcers, gastric problems (antiulcer)
Omnicef Infections (antibiotic)
Omnipen Infections (antibiotic)
ondansetron Nausea
Ortho-Cept Birth control pills
Ortho-Cyclen Birth control pills
Ortho-Novum Birth control pills
Ortho Tri-Cyclen Birth control pills
Oruvail Arthritis pain (anti-inflammatory)
oseltamivir Antiviral
oxaprozin Inflammation, pain, fever (anti-inflammatory)
oxcarbazepine Seizures
oxybutynin Bladder problems (antispasmodic)
oxycodone Pain (narcotic analgesic)
Oxy-Contin Pain (narcotic analgesic)
Pamelor Depression (antidepressant)
pantoprazole Gastric problems, ulcers
paroxetine Depression (antidepressant)
Pataday Allergies (antihistamine)
Patanol Allergies (antihistamine)
Paxil Depression (antidepressant)
Pediazole Infection (antibiotic)
penicillin Infection (antibiotic)
pentoxifylline Vascular disease (blood thinner)
Pepcid Ulcers, gastric problems (antiulcer)
Percocet Pain (narcotic analgesic)
Percodan Pain (narcotic analgesic)
Persantine Thromboembolism
phenazopyridine Urinary tract irritation, infection
Phenergan Nausea (antiemetic)
phenobarbital Seizure disorder (anticonvulsant)
phentermine Weight loss
phenytoin Seizure disorder (anticonvulsant)
Plavix Thromboembolism (antiplatelet)
Plendil High blood pressure (calcium-channel blocker)
potassium chloride Potassium replacement, taken with diuretics
Prandin Diabetes (oral antidiabetic)
Pravachol High cholesterol (cholesterol-lowering agent)
prednisone Severe inflammation (anti-inflammatory)

Premarin Menopause, gynecologic problems (estrogen)
Prempro Menopause, gynecological problems
Prevacid Ulcers, gastric problems (antiulcer)
Prilosec Ulcers, gastric problems (antiulcer)
Prinivil High blood pressure (ACE inhibitor)
Pro-Banthine Peptic ulcer (anticholinergic)
Procan Rapid heart rate, tachycardia (antiarrhythmic)
Procardia Heart problems, angina (coronary vasodilator)
Proloprim Infection, mainly urinary tract (antibiotic)
promethazine Nausea (antiemetic)
Propacet Pain management (narcotic analgesic)
Propecia Hair loss
propoxyphene Pain management (narcotic analgesic)
propranolol High blood pressure, heart problems, angina (beta blocker)
Proscar Prostate enlargement
Protonix Gastric problems
Proventil Breathing problems (bronchodilator)
Provera Gynecologic problems (progestogen)
Provigil Narcolepsy
Prozac Depression (antidepressant)
Pulmicort Asthma
Pyridium Urinary tract infections, pain
Quinaglute Ventricular arrhythmias (antiarrhythmic)
quinapril High blood pressure (ACE inhibitor)
Qvar Asthma, breathing problems (anti-inflammatory)
ramipril High blood pressure (ACE inhibitor)
ranitidine Ulcers, gastric problems (antiulcer)
Reglan Nausea (antiemetic)
Relafen Inflammation, pain (anti-inflammatory)
Remeron Anxiety, depression (sedative)
Restoril Sleep disorders (hypnotic)
Retrovir Antiretroviral
Risperdal Psychological disorders (antipsychotic)
Ritalin Attention deficit disorder, narcolepsy
Robaxin Muscle spasms (muscle relaxant)
Roxicet Pain management (narcotic analgesic)
Rythmol Heart problems, ventricular tachycardia
Sectral High blood pressure (beta blocker)
Septra Infection (antibiotic)
Serevent Asthma, breathing problems (bronchodilators)
Seroquel Psychological disorders (antipsychotic)
sertraline Depression (antidepressant)
Serzone Depression (antidepressant)
simvastatin High cholesterol
Sinemet Parkinson's disease (anti-Parkinson)
Sinequan Anxiety, depression (antidepressant)
Singulair Asthma
Skelaxin Muscle relaxant
Slo-Bid Breathing problems, asthma (bronchodilator)
Slow-K Potassium replacement, taken with diuretics
Soma Muscle spasms (muscle relaxant)
Spiriva Breathing problems
spironolactone High blood pressure, heart failure (diuretic)

Suboxone Treatment of opioid dependence
sucralfate Ulcers (antiulcer)
Sular High blood pressure
sulfamethoxazole Infection (antibiotic)
sulfasalazine Ulcerative colitis (antibacterial)
sulfisoxazole Infection (antibiotic)
Sumycin Infection (antibiotic)
Suprax Infection (antibiotic)
Sustiva Antiretroviral
Symbicort Asthma
Synthroid Thyroid disease (thyroid hormone)
Tagamet Ulcers, gastric problems (antiulcer)
Tamiflu Antiviral
tamoxifen Cancer (antineoplastic)
Tavist Allergies (antihistamine)
TegretoI Seizure disorder (anticonvulsant)
temazepam Insomnia (sedative)
Tenex High blood pressure (alpha blocker)
Tenormin High blood pressure, heart problems, angina (beta blocker)
Tequin Infection (anti-infective)
terazosin High blood pressure (alpha blocker)
tetracycline Infection (antibiotic)
Theo-Dur Breathing problems (bronchodilator)
theophylline Breathing problems (bronchodilator)
Tiazac High blood pressure
Ticlid Stroke (antiplatelet)
Tigan Nausea and vomiting (antiemetic)
Tofranil Depression (antidepressant)
Tolinase Diabetes (oral antidiabetic)
Topamax Seizures
Toprol High blood pressure (beta blocker)
Toradol Short-term pain
tramadol Pain (analgesic)
trazodone Depression (antidepressant)
Trental Vascular disease (blood thinner)
triamterene High blood pressure (diuretic)
Triavil Anxiety, depression (antidepressant)
Tricor High triglycerides (antilipemic)
trimethoprim Infection, mainly urinary tract (antibiotic)
Trimox Infection (antibiotic)
Triphasil Birth control pill
Trivora-28 Birth control pills
Tussionex Cough (antitussive)
Tylenol with codeine (Tylenol #3) Pain
Ultram Pain (analgesic)
valacyclovir Herpes (antiviral)
Valium Anxiety (antianxiety)
valproic acid Seizure disorder (anticonvulsant)
Valtrex Herpes (antiviral)
Vantin Infections (antibiotic)
Vasotec High blood pressure, heart failure
Veetids Infection (antibiotic)
venlafaxine Depression (antidepressant)

Ventolin Breathing problems (bronchodilator)
verapamil Angina, high blood pressure, rapid heart rate
Viagra Male impotence
Vibramycin Infection (antibiotic)
Vicodin Pain (narcotic)
Vicoprofen Pain (narcotic analgesic)
Viramune Antiretroviral
Viread Antiretroviral
Voltaren Arthritis (anti-inflammatory)
Vytorin High cholesterol
warfarin sodium Blood clots (blood thinner)
Wellbutrin Depression (antidepressant)
Xalatan Glaucoma
Xanax Anxiety, depression (sedative)
Xenical Weight loss
Xopenex Breathing problems
Yasmin Birth control
YAZ Birth control
Zantac Ulcers, gastric problems (antiulcer)
Zerit Antiretroviral
Zestoretic High blood pressure
Zestril High blood pressure (ACE inhibitor)
Zetia High cholesterol
Ziac High blood pressure (beta blocker, diuretic)
Zithromax Infection (antibiotic)
Zocor High cholesterol (cholesterol-lowering agent)
Zofran Nausea
Zoloft Depression (antidepressant)
zolpidem Sleep aid
Zomig Migraine headaches
zonisamide Seizures
Zovirax Herpes, shingles, chicken pox (antiviral)
Zyflo Asthma
Zyloprim Gout
Zyprexa Psychological disorders (antipsychotic)
Zyrtec Allergies (antihistamine)

CRITICAL CARE AIR TRANSPORT CLINICAL PRACTICE GUIDELINE

Negative Pressure Wound Therapy (CPG ID:49)

The goal of this clinical practice guideline (CPG) is to optimize wound management for the traumatically injured with a focus on the aeromedical evacuation (AE) environment. The series is developed by the Center for Sustainment of Trauma and Readiness Skills, University of Cincinnati Medical Center.

- What to do for small amounts of bloody output: 11

Fixed (Expected Clinical Proficiency) 12
References 12
Appendix A: Use of Impact Suction 13
Appendix B: How to Construct an Instillation or Irrigation NPWT dressing 14

Major updates

1. An algorithm for treating bleeding with a negative pressure wound therapy Negative Pressure Wound Therapy (NPWT) dressing has been included.

2. Appendix A which describes how to replace the KCI suction pump with the Impact suction has been added.

3. Appendix B which describes how to convert the KCI Vacuum Assisted Closure (VAC) Freedom to an instillation NPWT dressing has been developed.

Goal

This CPG provides an overview of negative pressure wound therapy and its uses in the treatment of soft-tissue battle wounds. It describes the technical aspects of troubleshooting negative pressure wound therapy, addresses equipment and dressing failures; and provides an algorithm for how to treat bleeding that may occur during patient evacuation. Throughout the guideline, a focus has been placed on the special conditions associated with en route care.

Background

NPWT promotes wound healing through the application of a vacuum paired with a sealed dressing; the benefits of wound healing seem independent of the type of NPWT system used.[1] The continuous vacuum draws fluid out from the wound[2] and also increases blood flow to the area.[3] Studies could not demonstrate, however, that wound bacterial counts were lowered.[4,5] In general, NPWT decreases wound edema and accelerates the healing process.[6] The vacuum may be applied continuously or intermittently, depending on the type of wound being treated and the clinical objectives. The continuous mode of suction is most commonly used for surgical wounds. Some NPWT devices allow delivery of fluids, such as saline or antibiotics to irrigate the wound; intermittent removal of used fluid supports the cleaning and drainage of the wound bed.[7] In addition, NPWT dressings are well-suited for use for patients with an open abdomen or chest after damage control surgery.[8] For these reasons, NPWT has become the preferred alternative to wet-to-dry dressings and other temporary wound coverage methods, particularly in the aeromedical evacuation (AE) environment. Thus, each Critical Care Air Transport Team (CCATT) member must thoroughly understand the NPWT equipment, how to troubleshoot device and dressing malfunctions, and manage associated complications. The only flight-approved commercial NPWT system is the KCI VAC Freedom. KCI provides a thorough clinical practice guideline for clinicians.[9]

Advantages of NPWT

Negative pressure dressings can be left in place for 24 to 72 hours, depending on wound characteristics. This makes the NPWT dressings generally less labor-intensive to manage and more ideal for AE.

NPWT allows for the accurate measurement of fluid and blood loss from wounds, to include losses associated with temporary abdominal and chest closures after damage control surgery. Understanding wound-related fluid losses is an important part of optimizing post-surgical resuscitation.

Techniques of NPWT

The term "wound VAC" has become synonymous with the KCI negative pressure therapy system. The KCI VAC Freedom is the only commercially approved device certified for use during AE. For that reason the KCI system will be reviewed in detail below, but it is important to understand multiple ways exist to create a negative pressure dressing.

NPWT systems can be fashioned using a standard portable suction device and dressing supplies. For example, NATO and Role 2 facilities often create negative pressure dressings using gauze or surgical towels covered with an occlusive dressing such as Ioban/Tegaderm and surgical drains connected to suction tubing. The open abdomen NPWT dressing, constructed as such, is sometimes referred to as a "Balad Pack" or "VAC Pack".

If a non-KCI device (other than the Impact suction device) is being used in-flight, then a waiver must be obtained for its use. As an alternative, the non-approved suction device can be replaced with the standard CCATT Impact suction device adjusted to a continuous mode of suction.

Components of a NPWT Dressing

There are **six components** to a NPWT system.

(1) Porous material:

- It is usually cut to fit into the wound to conform to its shape. This allows the negative pressure to be distributed evenly throughout wound and facilitates fluid egress.
- Examples of porous materials include (1) Reticulated Open Cell Foam (ROCF) is used in the KCI system and it is the type of material most commonly used; (2) sterile gauze; and (3) sterile surgical towels.

(2) Occlusive dressing:

- The entire wound must be covered and the dressing adherent to the intact surrounding skin; an additional topical adhesive (such as benzoin) can improve the success of creating an airtight seal.
- The materials most often used are either the KCI-branded adhesive dressings or Ioban (particularly for large wounds), however, other adhesive plastic dressings, such as Tegaderm may also be used.
- The skin must be dry for the dressing to stick well and remain occlusive; an airtight seal is required to allow the suction device to maintain negative pressure within the wound.

(3) Suction conduit:

- Tubing transmits the negative pressure from the suction device to the dressing.
- With the KCI system there is a device called the SensaT.R.A.C. Pad that is attached to the end of the tubing. The SensaT.R.A.C pad is placed over an opening created in the underlying dressing. This part of the dressing is also referred to as the "lily pad".

- Other conduits may include non-collapsible chest tubes, suction tubing, and surgical drains (with or without Heimlich valves).

(4) Y-connector:

- Allows a single suction device to be used for multiple small wounds.
- This arrangement may be less effective in maintaining negative pressure if the combined size of the wounds is too large.
- A challenge with y-connected dressings is that a leak in any one of the attached dressings will cause loss of suction in all wounds and result in fluid accumulation within the dressings and wounds themselves.
- Contaminated or infected wounds should not be connected via y-connecter to any other wound.[9]

(5) Fluid collection canisters:

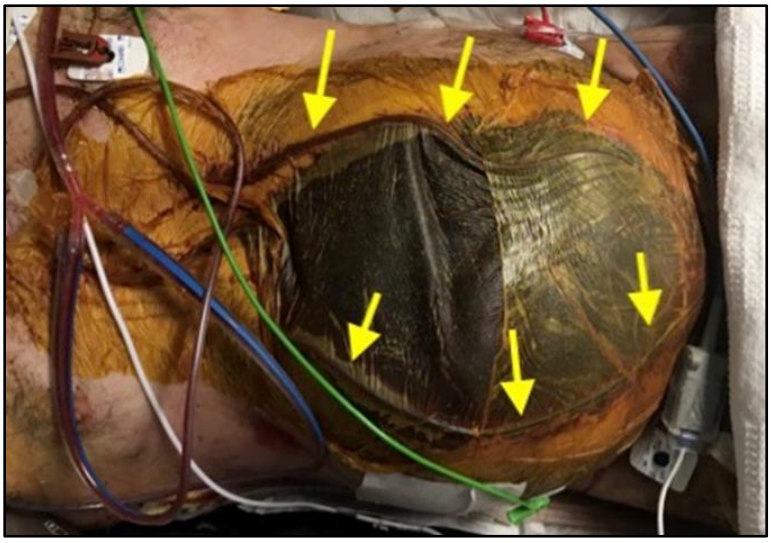
- Canisters collect blood and fluids removed from the wound and facilitate accurate I/Os.
- The VAC Freedom collection canisters are small (300 ml) and contain a gel pack to solidify fluids removed from the wound; these canisters cannot be emptied or reused. Calculate canister requirements carefully before departing on any AE missions.
- Fluid can be collected in standard suction canisters using the Impact suction device. These canisters may be reused if adequate supplies during flight are not available, but this should be avoided.

(6) Suction device:

- The KCI VAC Freedom is the only NPWT device approved for use in AE.
- The Impact suction device can also be used for NPWT. If the Impact suction device is used, ensure settings reflect the original orders for NPWT (i.e. continuous at -125mmHg). See Appendix A.

Figure 1. Temporary abdominal closure

Figure 1 demonstrates a temporary abdominal closure following a trauma laparotomy. A perforated clear plastic sheet was first placed directly on the bowel, followed by blue OR towels (usually a black sponge is used). Two nasogastric tubes (NGTs) were then placed on top of the towels (see arrows), followed by an Ioban seal. Finally, the NGTs were attached to an Impact suction device.



Operation of the KCI NPWT System

Continuous versus Intermittent Settings

Continuous therapy provides a constant level of negative pressure, and intermittent therapy cycles between negative pressure and zero pressure. Most wounds are managed with continuous therapy.

Negative Pressure Settings

The units are set in millimeters of mercury (mmHg) and the surgeon who placed the device will generally set the suction parameters; the majority of wounds will be managed with -125 mmHg of continuous suction. NPWT dressings that cover skin grafts may have lower settings such as -75 mmHg of continuous suction.

Suction Intensity

This determines intensity with which the pump reaches the set negative pressure. The value is set between 0 and 10. NPWT may cause mechanical deformation of the wound edge that can cause increased pain to the patient. Adjusting the suction pressure and intensity can help with the patient's pain, while ensuring therapeutic NPWT goals are still met.

Preflight NPWT Checklist

There are **eight elements** to consider when planning an AE mission with a patient that has a NPWT dressing.

(1) Understand the nature of wound:

- An understanding of the nature of the wound and underlying injury will aid the provider in troubleshooting NPWT dressing issues. This is critical for both soft tissue wounds on the extremities and for NPWT management on the abdomen. For example, patients with a midline abdominal wound VAC may have the abdominal wall (fascia) closed with a wound VAC applied to the skin/soft tissue only (called an "incisional wound VAC"), or the abdominal wall (fascia) may have been left open temporarily with the wound VAC communicating directly with the intra-abdominal contents (called a "temporary abdominal closure," "TAC," or AbThera).
- Failure of an incisional wound VAC (fascia closed) in flight can be remedied by simply switching to wet-to-dry dressings.
- Failure of an open abdominal wound VAC/AbThera in flight will likely lead to evisceration.
- Placing a NPWT dressing directly over a vascular repair is contraindicated. However, if a vascular repair has good soft tissue coverage (i.e. muscle), some surgeons will utilize NPWT to manage large associated soft tissue injuries. It is important to understand whether the wound contains a vascular repair; the location of the repair would be the best place to first apply manual pressure if life-threatening bleeding were to develop (see section, Special Considerations).

(2) Ensure the dressing has an airtight seal:

The NPWT adhesive dressing should have an airtight seal along all wound edges. With suction applied, the dressing should be firm and obviously under negative pressure. If it does not, then examine and repair the dressing with the surgeon that placed it if available.

(3) Identify any areas at risk for leakage during flight:

Examine the edges of the dressing closely to determine whether there are areas at risk for developing leaks (i.e. skin folds, creases, dressings applied over hair). Address these areas by modifying or reinforcing the dressing prior to departing the MTF.

(4) Identify any undrained fluid under the dressing:

It is important to inspect the dressing for any undrained fluid building up under the dressing. If this fluid continues to accumulate, the dressing will ultimately separate from the skin with loss of the airtight seal, failure of the dressing to maintain suction, collection of fluid in the wound bed, and leaking of fluid from the dressing. If not corrected fairly quickly, the dressing may not be able to be repaired without completely replacing the entire dressing.

(5) Prepare extra supplies that may be necessary during flight:

Extra canisters, (2) Ioban and/or Tegaderm to reinforce the dressing if an in-flight leak develops, (3) benzoin or other topical adhesive to facilitate dressing adherence if repair is

required, (4) additional suction adjuncts such as additional bubble tubing, Y-connectors, and "football" connectors, and (5) a shaving razor to remove hair prior to dressing reapplication may all be required to successfully troubleshoot and repair a malfunctioning NPWT dressing.

(6) Determine the number of canisters required for flight:

- The VAC Freedom NPWT canisters are small (300 ml). They cannot be emptied or reused; the pump will automatically shut off when the canister is full.
- It is imperative that enough canisters are taken as extra supplies to last for the duration of the flight. Check the hourly wound output for the prior 24 hours to help estimate the number of required canisters. If the Impact suction is being used instead of the KCI pump, the impact canisters are larger and can be emptied and reused if absolutely necessary.

(7) Develop an in-flight NPWT failure plan:

Prior to departure, it is reasonable to discuss with the surgeon whether a particular NPWT dressing may be safely converted to a wet-to-dry dressing if equipment issues cannot be overcome. This is easiest in smaller wounds with minimal output.

(8) Consider power and outlet access:

- Electrical cable assembly system (ECAS) setups may support as few as 4-7 power outlets per patient. The number of wound VACs per patient may exceed this capability. Constant vigilance will be needed to ensure the wound VACs remain charged. Rotating power cords between devices may be necessary.
- Each VAC Freedom draws 1 ampere of power; this must be taken into consideration in pre-mission planning with AE.
- In the event of power cord shortage, the Ranger Glidescope power cable is compatible with the KCI VAC Freedom.

Addressing NPWT Dressing Failure in Flight

The most common problem CCAT teams face is the inability to maintain negative pressure. This is most commonly the result of a leak at the edge of the adhesive dressing.

Review of the KCI System Alarms

- **Leak detected alarm**: sounds if the device is unable to maintain negative pressure in the wound; strategies for repair are detailed below.
- **Tube obstructed alarm**: sounds if the tubing is obstructed or if the canister is full.
  - First check the canister and replace it if it is full; ensure the canister is properly seated on the pump. Replace the canister if no other causes are found.
  - Check the tubing to ensure that there are no clamps or blood clots occluding it.
  - Increasing the level of suction may help maintain tubing patency but this should generally only be done after consulting with the physician who placed the device, if possible.

How to detect the loss of negative pressure:

- The dressing (or dressings if "Y" connected) will no longer be firm and collapsed.
- The KCI alarm sounds.

  Note that there is no "loss of suction" alarm on the Impact suction device.

How to identify the site of a NPWT dressing leak:

- Begin with a thorough inspection of the pump, canister, and all tubing connections to quickly eliminate these as a source of suction loss.
- Leaks around the edges of the adhesive dressing are the most common source of leaks. To identify the exact leak site, push along the edge of the dressing in sections to determine if the leak seals with manual compression.
- Large leaks may make a hissing sound that may be detected by listening closely; this may be nearly impossible to detect in-flight due to aircraft noise, so check prior to departure.

How to repair a dressing if the leak site has been identified:

- Simple reinforcement with additional adhesive dressings can repair most leaks.
- Before placing a patch on the dressing (most commonly the edge with require repair), the skin should be thoroughly cleaned, dried, hair removed, and a supplemental adhesive (i.e. benzoin) should be applied to maximize the chances of a successful seal.
- In complex dressings with multiple wounds attached to a single suction source, it may be possible to preserve suction on the dressing by excluding a single wound that is responsible for the loss of pressure on the entire dressing. After excluding the wound with the leak, work to identify the leak in the dressing and repair if possible.

How to repair a dressing if the leak site could not be identified:

If no obvious leak source is identified, an attempt should be made to cover the entire existing adhesive dressing with a larger sheet of Ioban. Depending on the size and location of the wound, this may or may not be possible. Again, drying the original dressing and skin and following with benzoin may increase the chances of obtaining an airtight seal. Avoid circumferential limb dressings.

What to do if a dressing leak cannot be repaired:

- If efforts to resolve the loss of suction are unsuccessful, teams should resort to the contingency plan established before flight departure; discuss these options with the sending physician prior to departing the MTF. Depending on the remaining transport time, size/location of the wound, and wound output, one of the following strategies can be selected:

  1. Leave the dressing in place and attach Impact suction at higher suction level. The higher suction may help overcome losses from small leaks.
  2. Remove the dressing and replace with a traditional wet-to-dry dressing for any wound except for an abdominal or thoracic temporary closure. If you remove a VAC dressing, document number of sponges removed from the wound so that none are inadvertently left behind.

What to do if the equipment fails:

- If the KCI VAC Freedom fails in flight, it is usually appropriate to attach the dressing to a standard Impact suction device.
- In small extremity wounds with minimal output, it may be appropriate to switch to wet- to-dry dressings.

In-flight management and patient monitoring:

- Quantity and quality of drainage should be monitored hourly. Changes in either the quantity or character of the output should be discussed with the CCATT physician.
- The drainage should be monitored for frank blood; see the special considerations section for strategies to deal with bleeding from a NPWT dressing.
- Additional vigilance is required when using the Impact suction unit for NPWT as there are no alarms to alert the team to malfunctions or changes in output.
- For negative pressure therapy to extremities, document distal pulse exams hourly. If a change in pulse exam occurs, CCAT teams should urgently evaluate the reason for the change, and ensure that large or near-circumferential extremity dressings is not restricting blood flow due to worsening edema.[9]
- Negative pressure should be applied continuously to all NPWT dressings. Prolonged periods without suction allow fluid to accumulate in the wound, which will lead to dressing failure.
- Use padding to prevent pressure injury for wounds located on dependent areas of the body (i.e. back or buttock wounds on a supine patient).

Special Considerations

Placing a NPWT dressing directly over a vascular repair is contraindicated. However, if a vascular repair has good soft tissue coverage (i.e. muscle), a NPWT may be used to manage large associated soft tissue injuries. New or continuous bleeding from a wound with an underlying vascular repair should raise suspicion for failure of the vascular repair; this is an emergency that requires immediate attention. Significant bleeding can also occur from small branch vessels in the wound.

What to do if significant bleeding develops in-flight:

These steps apply to extremity/junctional wounds only, not to temporary abdominal or chest closures:

1. If a large amount of blood rapidly fills the wound VAC then apply manual pressure over the NPWT dressing, remove the suction, and call the other CCATT members for help.

2. If life-threatening bleeding from an extremity wound is identified (the patient is tachycardic or hypotensive):

    a. Maintain direct pressure over the wound and have a second CCATT member place a CAT tourniquet 2-3 inches proximal to the wound and tighten it until the bleeding stops. The NPWT dressing can be removed and the wound tightly packed with Kerlix or Combat Gauze and then wrapped with an ACE bandage or Coban. Arrange for a diversion to the nearest surgical facility.

b. Next decide when to release the tourniquet. This decision should involve the surgeon from the sending facility, if possible. Factors to consider are the patient's hemodynamic status, blood availability, experience level of the provider with packing surgical wounds, likelihood of arterial bleeding, and the projected time of arrival at a surgical facility. The tourniquet time should be less than 2 hours, if possible.

3. If extremity wound bleeding is significant but not life-threatening (the patient is normotensive and not tachycardic):

   a. Maintain direct pressure over the wound and have a second CCATT member position a CAT tourniquet 2-3 inches proximal to the wound; the tourniquet does not have to be tightened, but rather pre-positioned if bleeding worsens. The NPWT dressing can be removed and the wound tightly packed with Kerlix or Combat Gauze; and then the entire limb can be wrapped with an ACE bandage or Coban.

   b. If bleeding is significant during packing, then the tourniquet can be tightened for control until wound packing and pressure dressing are completed.

   c. Wound packing and a pressure dressing can control most wound bleeding. A surgical consult would be appropriate; consider emergency diversion if bleeding is not controlled.

4. If life-threatening bleeding is identified from a groin or axilla junctional wound (the patient is hypotensive or tachycardic):

   a. If direct pressure does NOT control the bleeding, rapidly remove the NPWT dressing, pack the wound with Combat Gauze or Kerlix, and again apply direct pressure. Divert to the nearest surgical facility; obtain an in-flight surgical consult.

   b. If direct pressure over the NPWT dressing DOES control the bleeding (the NPWT dressing no longer fills with blood), continue holding pressure and consult surgery in-flight.

   c. Next decide whether the NPWT dressing should be removed to pack the wound. This decision should involve the surgeon from the sending facility, if possible. Factors to be considered are the patient's hemodynamic status, blood availability, experience level of the provider with packing surgical wounds, likelihood of arterial bleeding, presence of a vascular repair, and the projected time of arrival at a surgical facility.

   d. If the patient-to-CCATT ratio allows, maintain manual pressure using a team member rather than converting to a junctional tourniquet as manual pressure may be more reliable. Placement of the junctional tourniquet is not always straightforward and may increase limb ischemia.

5. If non-life-threatening bleeding is identified from a groin or axillary junctional wound (the patient is not hypotensive or tachycardic):

   Remove the NPWT dressing and pack the wound tightly and apply a pressure dressing to the entire limb. The junctional tourniquet can be used (may not need to be fully inflated) to maintain pressure if manual compression cannot be maintained because CCATT members cannot be spared from other patient care. Emergency diversion should be considered; an in-flight surgery consult would be appropriate.

6. Bleeding from a neck wound can be managed with direct pressure, then remove NPWT dressing followed by wound packing as described above. Emergency diversion should be considered for surgical evaluation; discuss with sending surgeon in-flight.

7. Anticipate resuscitate requirements for a bleeding patient. Do not wait for shock to develop. Replace blood with blood, not crystalloid.

What to do for small amounts of bloody output:

If bleeding develops from a NPWT dressing that doesn't cover a vascular repair, and if the volume is small, monitor the character and volume of output and consider reducing the suction. Reducing the suction may decrease the wound output, but it may also allow buildup of blood under the sponge where you can't see it. If there is concern about persistent ongoing active bleeding, get help and good lighting and remove the dressing, control the bleeding if possible, and pack the wound with Kerlix or Combat Gauze and wrap the limb with an ACE bandage or Coban.

The open abdomen:

- A leak from a NPWT dressing on an open abdomen may rapidly progress to evisceration if not repaired. A malfunctioning open abdomen dressing should be aggressively repaired in flight but not removed/replaced. (See strategies for NPWT failure in flight.) Chemical paralysis will help reduce the chance of evisceration in the event of malfunctioning open abdomen dressing.
- A temporary abdominal closure does not always evacuate all the blood in the abdomen, so it is possible for a patient to bleed into their abdominal cavity without a significant increase in the wound VAC output. This diagnosis requires close observation and continuous evaluation of hemodynamics. Markers of intravascular volume status (i.e. urine output, PPV, base deficit, TTE) should be also used.
- It is important to recognize that abdominal compartment syndrome can occur in spite of an open abdomen. If there is clinical suspicion (hypotension, low urine output, elevated peak airway pressures on the ventilator in volume mode), assess intraabdominal pressure by transducing a bladder pressure – greater than 20 mmHg may indicate abdominal compartment syndrome.

The open chest:

A chest that has been temporarily closed should have a chest tube(s) placed inside the chest, as well as a suction catheter coming from the wound itself. The chest tubes AND the suction catheter need to be kept to suction per surgeon instructions, and the output from all chest drains needs to be monitored hourly. A malfunctioning NPWT on an open chest should undergo troubleshooting but not removed/replaced in-flight.

Fixed (Expected Clinical Proficiency)

CCATT members are expected to understand the following:

1. The KCI VAC Freedom system.
2. The open abdomen and chest NPWT dressing.
3. The instillation NPWT dressing.
4. The troubleshooting and repair of the various NPWT dressings encountered in the AE environment.

Appendix A: Use of Impact Suction

This appendix describes one way to use the Impact suction if the KCI pump malfunctions in-flight.

1. Cut the NPWT/KCI tubing approximately one inch from the white connector on the canister side (left arrow). Cutting the tube on the canister side (not the wound side, right arrow) will allow a new KCI pump to be reconnected without forcing a NPWT dressing change/repair first. See Figure 1.

2. Place bubble tubing over the cut end of the tubing and partially push it over the white connector (marked by arrow) to create a seal; see Figure 2).

Figure 1

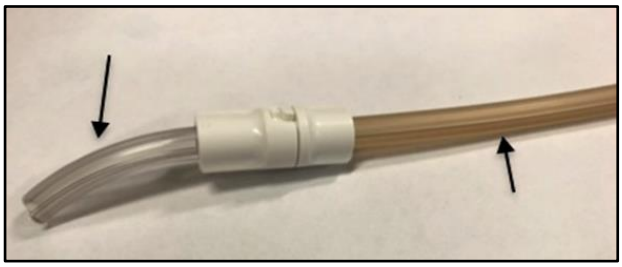

Figure 2

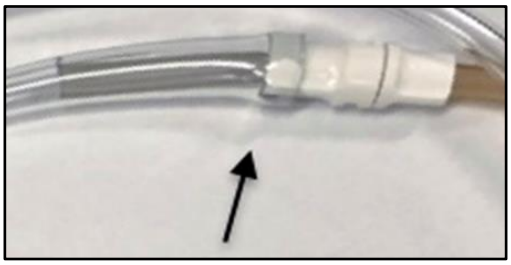

3. The bubble tubing can now be connected to the Impact suction as shown in Figure 3.

4. Ensure the suction strength is adjusted to reflect the surgeon's orders. For example, -125 mm Hg is approximately four green lights on the digital indicator, left side Figure 4.

Figure 3

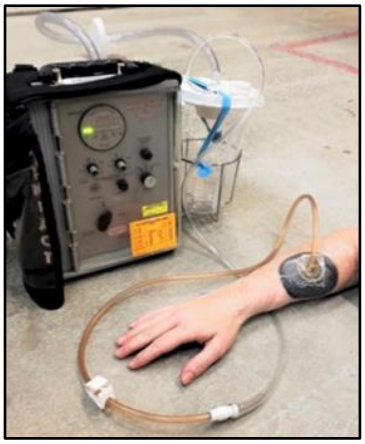

Figure 4

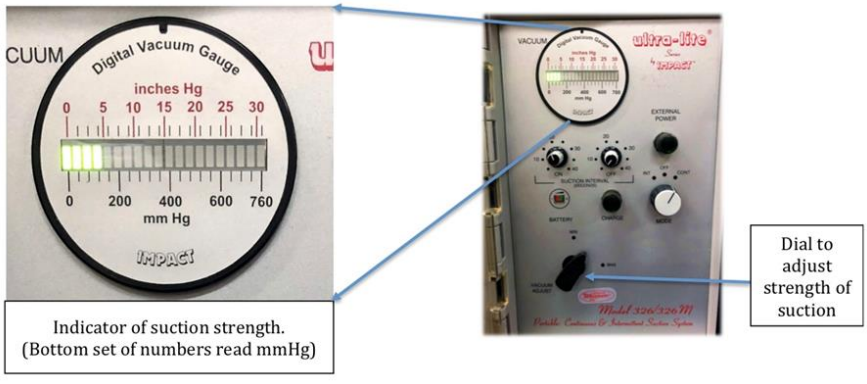
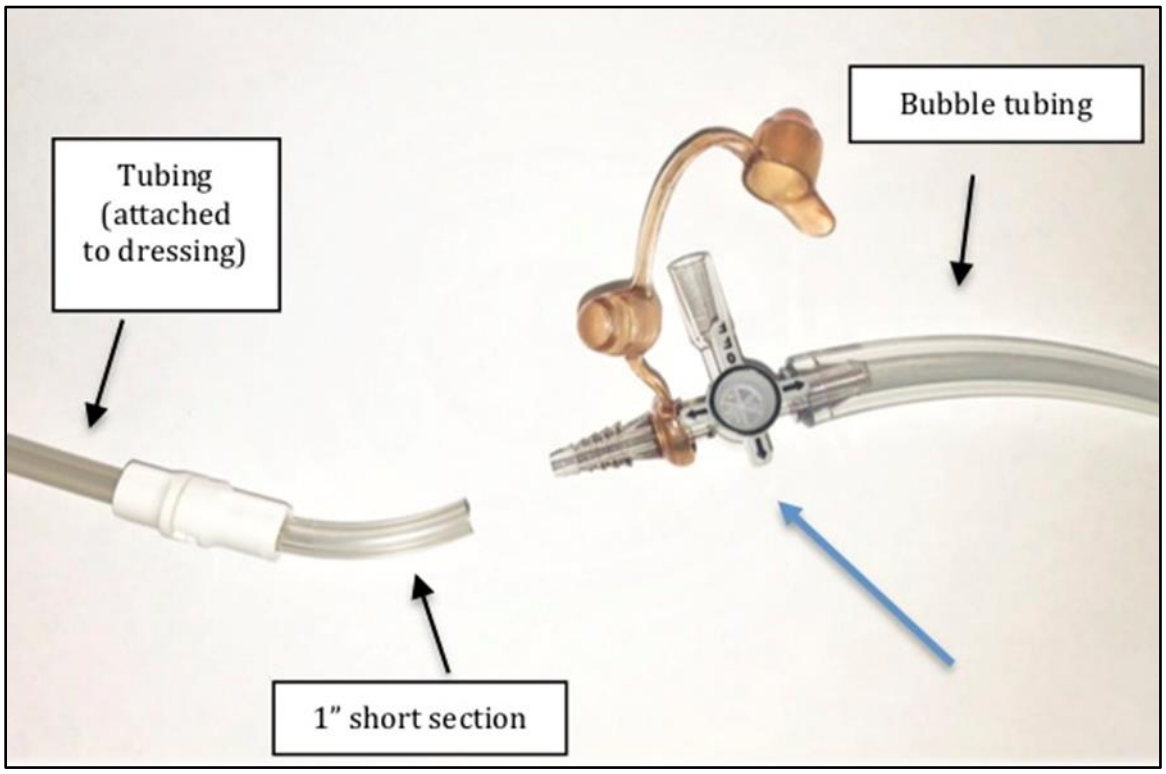


Appendix B: How to Construct an Instillation or Irrigation NPWT dressing

Refer to instructions below.



1. Cut the NPWT/KCl tubing approximately one inch from the white connector on the canister side.
2. Attach 3-way enteral stopcock (large arrow) between the bubble tubing and the one-inch short section; the other end of the bubble tubing connects to the suction.
3. Connect the two tubing sections in the figure to complete the NPWT circuit.
4. Irrigation procedure:
    a. Turn stopcock off to "suction."
    b. Instill medication.
    c. Keep suction off during medication dwell time (defined by surgeon.)
    d. Turn stopcock off to "syringe" and resume suction at previous settings.
5. Identify additional supplies and solution that will be needed during flight and retrieve items from the MTF prior to departure.
6. Using the impact suction is preferred because it has a larger capacity to collect irrigant and wound output.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Nursing Intervention in Prolonged Field Care (CPG ID: 70)

The intent of this guideline is to provide medical professionals who encounter extended casualty evacuation times in austere environments the evidence-based guidance for nursing interventions necessary to improve patient outcome.

INTRODUCTION

This Role 1, prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines when evacuation to a higher level of care is not immediately possible. A provider of PFC first must be an expert in TCCC. The intent of this guideline is to provide medical professionals who encounter extended casualty evacuation times in austere environments the evidence-based guidance for nursing interventions necessary to improve patient outcomes. Recommendations follow a "minimum, better, best" format that provides alternate or improvised methods when optimal hospital options are unavailable.

Basic activities of daily living become impaired or nonexistent depending on the severity of wounds. Simple tasks such as brushing teeth, breathing, drinking, coughing, moving extremities, and turning become impossible for an injured or unconscious patient. Thus, the patient requires regular assessments and nursing interventions to monitor their condition and prevent the development of complications.

Nursing interventions may not appear important to the medical professionals caring for a patient, but such interventions greatly reduce the possibility of complications such as deep vein thrombosis (DVT), pneumonia, pressure sores, wound infection, and urinary tract infection. Critically ill and injured casualties are at high risk for complications that can lead to adverse outcomes such as increased disability and death. Nursing care is a core principle of PFC to reduce the risk of preventable complications and can be provided without costly or burdensome equipment.

Using a nursing care checklist assists with developing a schedule for performing appropriate assessments and interventions.

Cross-training all team members on these interventions prior to deployment will lessen the demand on the medic, especially when caring for more than one patient.

ASSESSMENT

After initial stabilization, every patient requires regular assessments. Document results on a PFC flowsheet (Appendix A) and monitor trends to identify signs of decompensation. Initiate nursing interventions early to prevent further harm.

- **Minimum**: Manual blood pressure (BP) cuff, stethoscope, thermometer, pulse oximeter, glucometer, urinary catheter, flashlight, watch
- **Better**: Digital, wrist BP cuff
- **Best**: Portable monitor providing continuous vital signs display and capnography capability, glucometer

VITAL SIGNS

- Obtain BP, heart rate, respiratory rate, temperature, oxygen saturation, end-tidal CO2 (when available), Glasgow Coma Scale score, pain score, and peripheral pulses.
- Inspect and Monitor Tubes
- Examine all tubes (e.g., endotracheal tube [ETT] or cricothyroid tube, nasogastric [NG] tube, intravenous [IV] line, chest tube, urinary catheter) for correct placement and appropriate function, and ensure they are secured properly.

- High-volume burn resuscitation results in global edema and ETT/cricothyroid tube position must be closely monitored. Securing tubes with circumferential ties is required when burned skin weeps fluid.

***Caution**: NG tubes should only be placed when radiographic or intraoperative confirmation is available, or when the benefit outweighs the risk. Routine NG placement for unconscious or intubated patients is not recommended in austere environments.*

MONITOR INPUT AND OUTPUT

- Check IV drip rate or give oral fluids as needed.
- Ensure adult patients void an average of 30–50mL/h, or 100–200mL/h if exhibiting signs of rhabdomyolysis.
- Check drainage from wounds and tubes.

INSPECT SKIN AND SPLINTS

Examine skin, including nares and mouth, for changes and ensure splints are fitted properly and pulses are present below splint. Monitor for allergic reactions to tape, developing erythema, excessive dryness, pressure indenting the skin, cracking, or breakdown.

Nursing Interventions

Applicable nursing interventions are identified and adjusted after every assessment is completed. Interventions are individualized on the basis of each patient's illness or injury. Different interventions may be required depending on a patient's level of consciousness, and a previously conscious patient may become unconscious. Positioning a patient in a comfortable position with head and injured extremities elevated is a basic and important intervention; one positioning method is to use a trifold lawn chair, or similar improvised support, to maintain elevation of the patient's head and legs as needed.

The PFC nursing care plan (Appendix B) is a chart of nursing interventions with recommended intervals that the primary medical professional can fill out for the team to continue caring for a patient while the primary medical professional rests. Before deployment, medical professionals can use this tool to train teammates on nursing interventions so they can assist with patient care. Appendix C is an example of a completed chart with instructions.

PLAN AND DOCUMENT NURSING INTERVENTIONS

Minimum: Nursing care checklist portion of the PFC flowsheet (Appendix A)

Best: PFC nursing care plan (Appendix B)

FLUSH SALINE LOCKS

- **Minimum**: Empty 10mL syringe, needle, bag of normal saline (NS), alcohol pads
- **Best**: Prefilled 10mL NS syringes, needle (if applicable), alcohol pads

At least every 8 hours, flush saline locks with 10mL of NS.

1. Gather equipment.

2. Clean access port with alcohol pad.
3. Take prefilled 10mL syringe of NS and needle (if applicable) or attach syringe to port.
4. With constant pressure, inject NS into port to flush catheter to ensure line remains open.
5. If resistance is met, gently use pulsating pressure on end of syringe until NS flows freely.
6. Carefully observe the IV site for swelling or pain. Start a new IV if swelling or pain occurs.
7. Detach syringe and dispose; place needle in sharps container (if applicable).

If prefilled syringes are unavailable, draw up NS into unused, empty syringe from a bag of NS, then follow steps above.

SUCTION ADVANCED AIRWAY

- **Minimum**: Manual suction device or improvised suction device, such as a 25cm length portion of IV tubing connected to a 60mL syringe
- **Better**: Open suction tube, suction machine
- **Best**: Closed inline suction tube, suction machine

Perform airway suction only when needed, using sterile technique for advanced airways or clean technique for the mouth and throat. Humidify the air using a humidifier, moist gauze, or by boiling a pot of water.

1. Gather necessary equipment.
2. Ensure patient's head is elevated.
3. Perform hand hygiene.
4. Place a clean towel under patient's chin.
5. Don eye protection.
6. Hyperventilate patient for 10 seconds.
7. Perform appropriate suctioning with available equipment (ensuring suction is performed while withdrawing the catheter for no longer than 10 seconds at a time).
8. Allow at least 30 seconds before repeating suctioning, if needed.
9. Perform oral care as needed but at least every 4 hours.

REPOSITION AND CHECK PADDING

- **Minimum**: Extra clothing, soft items
- **Best**: Pillows, blankets, towels

Identify patients who cannot reposition themselves. Reposition patient and check padding at least every 2 hours. To prevent ischemic tissue injury and the formation of pressure sores, frequent movement of the patient

is necessary. Relieving pressure from superficial capillaries allows the skin to recover from the temporary ischemia.

1. Roll the patient onto one side (if concerned about spine injury, carefully log roll while maintaining spine stabilization).
2. Have an assistant remove pillows, blankets, or soft items being used for positioning and gently guide the patient down onto their back.
3. Using the same procedure, have assistant gently roll patient in the opposite direction.
4. Place pillows, blankets, or soft items under patient for positioning and have assistant guide patient back down.
5. Ensure the patient's ankles, knees, and elbows are not resting on top of each other and arms are not resting on the abdomen, by placing padding between them.
6. Ensure the patient's head and neck are in line with the spine.
7. Use additional padding items for bony prominences on hard surfaces.
8. Ensure creases and bumps in clothing, sheets, and blankets are smoothed out under the patient.
9. Be aware of the location of external equipment such as Foley catheter, IV tubing, and ventilator tubing to prevent dislodging during repositioning.
10. If any areas of nonblanchable erythema are noted, outline area with marker and prevent placing patient on the affected area until it recovers.
11. Burned and injured extremities should be slightly elevated and slightly flexed to optimize venous return and maintain adequate peripheral pulses.

ORAL CARE

- **Minimum**: Gloves, gauze, lip moisturizer
- **Better**: Mouth wash, mouth moisturizer, gloves, gauze, tongue depressor, tape, lip moisturizer
- **Best**: Oral cleansing and suction system, lip moisturizer

Good oral hygiene reduces oropharyngeal colonization, which is associated with ventilator-acquired pneumonia. Patients who are conscious and able should brush their teeth a minimum of every 12 hours. For unconscious patients, perform oral care at least every 4 hours. Ensure some type of suction is available (e.g., manual suction device, syringe with IV tubing).

- To keep the patient's mouth open, make a padded tongue depressor by wrapping gauze around one end of it and securing with tape.
- If available, use swab and chlorhexidine gluconate rinse from oral cleansing and suction system. Make sure not to oversaturate the swab to avoid aspiration of fluid. Clean teeth and oral cavity for approximately 1 minute. If the system is unavailable, use a 2×2 gauze wrapped around pointed gloved finger and hold firmly with the rest of hand. Moisten the gauze with mouthwash (ensuring not to oversaturate) and gently clean the teeth and mouth cavity. Multiple gauze swabs may be needed depending on the level of contamination in the mouth. Follow up with mouth moisturizer if available.

- Apply lip moisturizer.

FOLEY CATHETER CARE

Minimum: Basin, warm water, nonirritating soap, linen saver pad, towels

Perform Foley care once a day or as needed for excessive drainage.

1. Wash hands thoroughly with soap and water, apply gloves, and place linen-saver pad or dry towels under patient.
2. Using mild soap and water, clean genital area.
3. For male patient: retract the foreskin, if needed, and clean the area, including the penis.
4. For female patient: separate the labia, and clean the area from front to back.
5. Clean urethra (urinary opening), where the catheter enters the body.
6. Clean the catheter from where it enters the body and then down, away from urethra. Hold the catheter at the point it enters the patient so that tension is not placed on it.
7. Rinse the area well, dry gently, and replace linen-saver pad under patient.

WASH AND DRY SKIN, APPLY LOTION

- **Minimum**: Water, gauze, or well rinsed "baby" wipes
- **Bette**r: Bowl, baby or mild wash, unscented lotion, 2×2 and 4×4 gauze pads, gloves, tongue depressor, tape
- **Best**: Basin, linen-saver pads, disposable wash cloths, compression stockings, trifold lawn chair, nasal mist, pillows, padding, urine test strips, toothbrush and toothpaste, oral cleansing and suctioning kit, tongue depressor, gauze, tape

At least once per day or as needed, wash, dry, and apply lotion to skin. Cleaning the skin is an opportunity to evaluate additional injuries and visualize any new areas of erythema.

1. Prepare basin or bowl with warm water and a small amount of baby wash.
2. Obtain multiple 4×4 gauze pads or clean washcloths and place in water
3. Expose body part to be washed, keeping the rest of the patient covered, and place linen-saver pad under the area to absorb water.
4. Take one gauze or washcloth out of the basin and wring out excess water. Wash skin a little bit at a time, throwing away used gauze or washcloths until clean. DO NOT place contaminated gauze or washcloths back into basin or bowl.
5. Wash face first and genitalia last. (Cleaning genitalia is detailed under Foley care.)
6. Ensure the skin is thoroughly dried, including all skin folds, and apply lotion.

***Caution**: If baby wipes or skin wipes are used to wash the skin, the wipes should be thoroughly rinsed with water first, because most contain alcohol and residues that can irritate the skin.*

CHANGE INTRAVENOUS BAG AND TUBING

Every 72 hours if possible, replace infusing bag of fluids and tubing with new equipment. If fluids infusing at a to-keep-open rate and a bag has been up for 72 hours, ensure a fresh bag and tubing are hung and marked with new time and date.

CHECK BLOOD GLUCOSE LEVEL

If available, check blood glucose level (BGL) every 8 hours or more frequently as dictated by patient status. A low BGL (less than 80 mg/dL) must be treated immediately with oral sugar or juice or IV glucose. A high BGL (greater than 200 mg/dL) is less dangerous than low glucose, but may be treated if the capability is available.

CHANGE TAPE

1. Once a day, change tape on patient's skin (except for peripheral IV sites, which can be changed every 72 hours to avoid exposing puncture site to contaminants). Daily tape changes decrease the potential for skin breakdown. This intervention may be accomplished after patient's daily wash.
2. For ETT or cricothyroid tube, gently remove tape. If tape is strongly adhered, use an alcohol swab to moisten the top of the tape. As the tape is lifted back, use the alcohol swab and gently rub across the skin at the junction with tape to loosen, ensuring not to dislodge tube placement.
3. For ETT, after tape is removed, gently move the tube to the opposite side of the mouth, again ensuring not to dislodge it or rest on lip.
4. Apply new tape to a section of skin next to where tape was previously removed. To give skin a break, do not place over the same area.

LOWER EXTREMITY MASSAGE, DVT PREVENTION

If available, compression stockings, or elastic bandages (wrapped starting from the toes upward) should be placed on immobile or unconscious patients, ensuring toes remain exposed for capillary refill assessment. Patients who are conscious and able may perform the following exercises, completing 10 repetitions of each exercise every hour while awake. This may be done in burned extremities or in the presence of open wounds, but should be avoided when fractures or severe extremity injuries are present.

- **Foot pumps**. Have the patient stretch toes up and back, flexing feet, and hold for a few seconds. Then point toes and hold before repeating.
- **Ankle circles**. Have patient raise both feet and trace a circle or each letter of the alphabet with their toes
- **Leg raises**. With left leg straight, have the patient raise foot off the bed or floor, then lower. Repeat with right leg. Alternatively, slowly have patient lift left knee up to chest, then bring foot back to the bed or floor; repeat with right leg.
- **Thigh stretches**. While patient is lying on their back with straight legs, have them raise one leg to 90°. Instruct patient to pull the leg gently toward the head and hold for up to 30 seconds. Slowly bring leg back down to a flat position, and repeat with other leg.

- **Shoulder rolls**. Although developing a clot in the upper body is not likely, blood still needs to keep flowing. Have the patient raise shoulders and circle them back and down five times. Then reverse direction for five more repetitions.

Perform DVT prevention for unconscious patients at least every 2 hours.

- **Ankle plantarflexion-dorsiflexion**. Hold the ankle and heel of one foot and alternately bend the foot forward into plantarflexion and then push the foot upward into dorsiflexion. Hold each position for 5–10 seconds.
- **Lower extremity massage**. Using both hands and starting at the ankle, apply consistent pressure, massaging the leg in an upward motion through the thigh. (Items such as a plastic bottle may be used to roll the skin toward the head.) Ensure deep pressure is avoided when massaging behind the knee or over bony prominences. Alternate legs (to simulate walking) for five times on each leg.

RANGE OF MOTION EXERCISES

At least every 8 hours, perform range of motion exercises on all movable joints such as ankles, knees, hips, wrists, fingers, elbows, and shoulders, except where joint mobility is restricted by injury.

TURN, COUGH, DEEP BREATHE

1. For a conscious patient, encourage them to turn, cough, and take deep breaths to prevent atelectasis.
2. Instruct the patient to breathe in deeply and slowly through their nose, expanding lower rib cage, and letting abdomen move forward.
3. Hold for a count of 3 to 5.
4. Instruct patient to breathe out slowly and completely through pursed lips.
5. Have patient rest and repeat 10 times every hour.
6. Code Brown: Unconscious Patient Bowel Movement Recommend leaving unconscious patients unclothed from the waist down and covered with a sheet or blanket, with linen-saver pad or towel under the buttocks for easy bowel movement clean up. During assessment, check if the unconscious patient has had a bowel movement and clean if needed.
7. Gather a basin with warm, soapy water; rolled linen-saver pad or towel; gloves; and washcloths.
8. Have assistant log roll the patient toward them.
9. Start cleaning from top of patient toward soiled linen-saver pad or towel, obtain a new washcloth when current one is completely used.
10. When patient is cleaned as far as can be reached on that side, roll soiled pad or towel on itself to contain fecal matter and start to unroll new linen-saver pad, keeping clean one under dirty one.
11. Gently log roll patient to the other side and have assistant finish cleaning soiled area; dry completely.
12. Discard soiled pad or towel and finish unrolling clean pad, ensuring there are no folds under patient.
13. Gently roll patient to previous position of comfort and cover.

14. For nursing assessment and intervention packing list, see Appendix D.

15. Hospital clinical rotations are an excellent opportunity to learn and practice nursing assessments and interventions. The recommended nursing skills checklist for clinical rotations is included in Appendix E.

APPENDIX D: ASSESSMENT AND INTERVENTION PACKING LIST

The following list incorporates equipment categorized as "Best" although item substitutions categorized as "Minimum" may be described throughout performance steps.

- ☐ Portable Monitor
- ☐ Blood Pressure Cuff/Stethoscope/pulse oximeter
- ☐ Gloves
- ☐ Thermometer
- ☐ Urinary catheter
- ☐ Linen-saver pads
- ☐ Watch
- ☐ Oral Cleansing and Suctioning Kit/Toothbrush/Toothpaste/Mouthwash/Tongue depressor
- ☐ Lip balm
- ☐ Nasal mist
- ☐ Baby/mild wash
- ☐ Unscented lotion
- ☐ Compression stockings
- ☐ Pillows/Blankets/HPMK/Padding
- ☐ Basin/Bowl
- ☐ Suction device
- ☐ Tri-fold lawn chair
- ☐ Flashlight or headlamp
- ☐ Syringes (various sizes)
- ☐ Skin marker
- ☐ Gauze pads (2x2, 4x4)/Washcloths
- ☐ Glucometer
- ☐ Medical tape
- ☐ Urine test trips
- ☐ Saline flushes

APPENDIX E: RECOMMEND NURSING SKILLS CHECKLIST FOR CLINICAL ROTATION

- ☐ Perform and document physical exam
- ☐ Perform vital sign monitoring
- ☐ Radial, DP/PT pulse check: manually/Doppler probe
- ☐ Perform finger stick blood sugar
- ☐ Perform phlebotomy
- ☐ Manually titrate IV fluid drip rates
- ☐ Monitor hourly urine output
- ☐ Perform US dipstick
- ☐ Measure gastric residual
- ☐ Insert Foley; perform Foley care
- ☐ Flush PRN IV locks
- ☐ Start peripheral IV
- ☐ Administer IV/oral medications
- ☐ Monitor GCS/pain (1 – 10 or nonverbal pain scale)/sedation levels (RASS scale)
- ☐ Effectively titrate analgesics
- ☐ Effectively titrate sedatives/daily wake up for neuro evaluation
- ☐ Insert OG/NG tube
- ☐ Perform Cric (Trach) care
- ☐ Endotracheal suctioning
- ☐ Perform oral suctioning
- ☐ Perform nasal care
- ☐ Perform oral care
- ☐ Apply lip balm
- ☐ Apply eye ointment/drops
- ☐ Brush teeth
- ☐ Change all tape
- ☐ Adjust ventilator settings: understand FiO2, TV, PS, PEEP, etc.
- ☐ Auscultate lungs
- ☐ Measure compartment pressures (extremities, abdominal)
- ☐ Perform wound care (trauma, burn)
- ☐ Irrigate wounds
- ☐ Debride wounds
- ☐ Auscultate and palpate abdomen
- ☐ Provide appropriate nutrition
- ☐ Perform escharotomy (animal lab, simulation)
- ☐ Insert IO (simulation: sternum, humerus, tibia)
- ☐ Perform neuro exam
- ☐ Calculate total burn size (Rule of nines, Lund-Brower)
- ☐ Calculate burn resuscitation: starting volume (Rule of 10's), total volume (Ivy Index)
- ☐ Titrate burn resuscitation fluid to meet target urine output
- ☐ Perform ultrasound FAST exam
- ☐ Perform blood typing using Eldon Card
- ☐ Perform blood donor screening procedure
- ☐ Reduce/splint fractures (Simulation)
- ☐ Convert tourniquet (Simulation)

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Nutritional Support Using Enteral and Parenteral Methods (CPG ID: 33)

How to achieve optimal nutritional support for the critically injured or ill patient using enteral nutrition and parenteral nutrition methods.

PURPOSE

- To define an approach to optimal nutritional support in the critically ill or injured patient.
- To establish meaningful goals for implementing enteral nutrition.
- To provide an understanding of the various formulations for enteral nutrition and their use.
- To establish the indications for total parenteral nutrition.

DEFINITIONS

- **Enteral Nutrition (EN):** The use of the stomach, duodenum, or jejunum to provide the nutrition targets to optimize healing and normal physiologic function.
- **Total Parenteral Nutrition (TPN):** Formulated nutritional substrate provided intravenously to optimize healing and normal physiologic function.

GUIDELINES

1. Consult medical nutrition therapy on all ICU patients for nutritional assessment and cooperative guidance on nutritional support.
2. Consider tele-consultation to next level of care if Medical Nutrition Therapy services are not available locally.
3. Enteral nutrition should be the first choice over total parenteral nutrition for the patients unable to consume food on their own. Enteral nutrition maintains gut mucosal integrity and immunocompetence.
4. When compared to parenteral nutrition, EN in appropriately selected patients has been associated with a decrease in infectious complications, decreased hospital length of stay and a significant reduction in ICU length of stay
5. It is important to note that the maximal benefit of enteral nutrition is obtained when it is started early (within 48 hours of admission) and that the benefit does not appear to be dose-dependent, so even low-rate (trickle) feeding can improve outcomes.[1,2]

ENTERAL NUTRITION

INDICATIONS FOR ENTERAL NUTRITION

1. Any patient on the trauma service who is anticipated to remain unable to take full oral intake on their own for greater than 5-7 days.
2. Any patient who has oral intake with supplementation that is inadequate to meet current nutritional needs (i.e., < 50% of estimated required calories for >3 days.)
3. Any patient with pre-existing malnutrition (>15% involuntary weight loss or pre-injury albumin < 3 g/dl) or categorized as “high nutritional risk” based on a validated nutritional risk scoring system and unable to immediately resume full oral intake. It should be emphasized that for albumin to be useful as a nutrition maker, it should be obtained prior to injury. However, in the combat trauma setting, a pre-injury albumin level is unlikely to be available. Further, albumin measured during acute illness should not be used or followed as a marker of nutrition as it is an acute phase reactant and will markedly

decrease during the initial period of critical illness. An initial pre-albumin level is also less useful immediately after injury, but serial pre-albumin levels can be useful during the resolution and recovery phase. If utilized pre-albumin should not be checked more frequently than once weekly.[1-4]

ABSOLUTE CONTRAINDICATIONS FOR ENTERAL NUTRITION

1. High risk for non-occlusive bowel necrosis
   - Active shock or ongoing resuscitation
   - Persistent mean arterial pressure (MAP) < 60mmHg
   - Increasing requirement for vasoactive support to maintain MAP>60mmHg
2. Generalized peritonitis
3. Intestinal obstruction
4. Surgical discontinuity of bowel
5. Paralytic ileus
6. Intractable vomiting/diarrhea refractory to medical management
7. Known or suspected mesenteric ischemia
8. Major gastrointestinal bleed
9. High output uncontrolled fistula [1-3]

RELATIVE CONTRAINDICATIONS FOR ENTERAL NUTRITION

- Body temperature < 96 F
- Concern for abdominal compartment syndrome as evidenced by bladder pressure > 25mmHg [1-3]

PARENTERAL NUTRITION

INDICATIONS FOR PARENTERAL NUTRITION

1. Unable to meet > 50% caloric needs through an enteral route by post-injury day #7
2. Any of the contraindications for enteral nutrition listed in above that persist and patient is without nutritional support for 3 days or patient is not anticipated to start enteral nutrition for more than 3-5 days.
3. Massive small bowel resection refractory to enteral feeds.
4. High output fistula after failure of elemental diet.
5. Any patient with pre-existing malnutrition (>15% involuntary weight loss or pre-injury albumin < 3 g/dl) or categorized as “high nutritional risk” based on a validated nutritional risk scoring system (NUTRIC or other) and with contraindication or intolerance to enteral feeding. [1-4]

ENTERAL ACCESS

1. Enteral access will be established ideally within 24 hours of admission to the Role 3 or higher Medical Treatment Facility (MTF).[1-3,5,6]
2. If the patient will be taken to the operating room within 24-48 hours of arrival for laparotomy procedure, a naso-jejunal feeding tube (NJFT) should be placed while the patient is in the operating room (OR). While in the civilian setting in intubated patients there is no difference in outcomes when comparing EN via the naso-jejunal versus gastric route, however enteral access distal to the stomach is recommended, particularly in those patients at risk for aspiration. Due to the intermittent nature of gastric feedings and the need for frequent holdings for patient aeromedical evacuation and/or procedures in the combat environment, it is emphasized that this is NOT the preferred initial method of feeding these patients. However if this is not practical, in many patients it is acceptable to initiate gastric EN. [1,3]
3. If the patient is not a candidate for operative placement, use whatever means available to place a feeding tube. (e.g., endoscopic, fluoroscopic, etc.).
4. If unable to place a NJFT, consider the use of an Oro-Gastric (OG) or Naso-Gastric (NG) tube, with intent to discontinue enteral feeds 6 hours prior to transfer.
5. If prolonged enteral feeding (>4 weeks) is expected, then placement of a surgical feeding tube should be considered. A gastrostomy, jejunostomy, or combined gastro-jejunostomy should be considered prior to final closure of any open abdomen patient, and the risks versus benefits of each option along with the existing patient gastrointestinal anatomy will dictate the choice of surgical feeding access. [1-6]

NUTRITIONAL ENERGY/PROTEIN REQUIREMENTS

Nutritional energy/protein requirements are based on the patient's current nutritional status and severity/type of trauma suffered. The previous practices of over-feeding critically ill or injured patients by multiplying a calculated caloric goal by some "stress factor", or increasing caloric intake above the goals calculated per the below guidelines, should NOT be applied to the ICU patient. This is associated with no nutritional benefit but a significant increase in the risk of adverse events and complications associated with overfeeding. [1, 2] Table 1 lists some basic guidelines and Table 2 lists vitamin and mineral supplementation recommendations.[1-3]

Table 1. Enteral Feeding Calculations	
Body Mass Index (BMI)	(wt in kg) / (ht in m)^2
Ideal Body Weight (IBW)	Male: (50kg) + (2.3kg per inch over 5ft) Female: (45.5kg) + (2.3kg per inch over 5ft)
Kcal	High Stress Trauma/Burn: 25-35 kcal/kg/day dry wt
	Vent (>72 hours) or ARDS: 20-25 kcal/kg/day dry wt
	Obese (BMI>30): 22-25 kcal IBW or 11-14 kcal/day actual wt
Protein	Major Trauma/Burn/TBI: 1.5-2.0 g/kg/day *Large Burn may need up to 1.5-2.0 g/kg/day
	Obese (BMI>30): 2g/kg/day IBW
	Most patients: 1.2-1.5 g/kg/day
Fat	15-30% of kcal
	15-20% of kcal in major burns
Free Water	1ml/kcal

Table 2. Vitamin and Trace Mineral Supplementation	
Continue for 7 days and then re-assess patient's clinical and nutritional condition. [1,18-20]	
**Closely Evaluate Dosing in Renal and liver Failure patients.	
Vitamin C	500 mg IV daily if CrCl<30ml/hour Note: Higher doses of Vitamin C may increase or contribute to diarrhea
Zinc Sulfate	220 mg tab by mouth once a day for no more than two weeks
Vitamin E	1000-1200 IU PO/OG/NG/NJFT every eight hours
Selenium	200 mcg IV or PO/OG/NG every 24 hours
Multivitamin Tab, Elixir, or IV once a day	Prenatal vitamins are often an excellent choice for supplementation if iron is also needed. For those unable to swallow a large pill or for whom the iron causes GI upset, children's chewable vitamins are well tolerated.

SPECIAL CONSIDERATIONS

Use caution when evaluating the injured active duty population. Many are young, healthy, and very muscular. If they are muscular with a BMI > 30, you should use their estimated actual weight pre-injury. Those with a BMI > 30 due to obesity should use the IBW when indicated as stated above. Pick any of the above formulas you like as they are all 70–80% accurate compared to a metabolic cart study, which is not available until the patient reaches the U.S. and should be used as soon as possible to obtain the gold standard for caloric and macronutrient requirements.

ROLE OF HYPOCALORIC FEEDING

Although 25-35 kcal/kg/day has been widely utilized as a caloric target when feeding critically ill patients, there has been a growing body of literature that suggests that permissive underfeeding with lower caloric targets is as effective as higher calorie targets and may decrease morbidity from overfeeding or from other adverse effects of delivering a full nutritional load to a metabolically stressed patient. There have been several recently published randomized trials (EDEN and PERMIT)[8-10] in mixed critically ill patients and in surgical patients only 11 that have shown equivalent primary outcomes with hypocaloric (10 kcal/kg/day) feeding versus normocaloric (25-35 kcal/kg/day). However, a meta-analysis suggests improvement in some secondary outcome measures with the hypocaloric approach.[12] Currently, a hypocaloric approach is a reasonable alternative in patients with low or intermediate nutritional risk (based on NUTRIC or other scoring system) and no pre-existing malnutrition, and may decrease select complications such as feeding intolerance, diarrhea, and high gastric residual volumes. Further, hypocaloric feeding (10-20 kcal/kg) has also been found to have multiple benefits in patients with pre-existing obesity (BMI>30) by reducing excessive fat stores while simultaneously preserving lean body mass. However, it is critical when using a hypocaloric approach in ANY patient to understand than "hypocaloric" refers to non-protein calories, and that it must always be accompanied by full and adequate protein delivery (typically 1.5 to 2 grams/kg ideal body weight).[1,2]

FORMULA SELECTION

1. High protein, volume concentrated formula (e.g., IMPACT® or equivalent). A formula with fiber would be contraindicated in patients who are at risk for bowel ischemia or are hemodynamically unstable. [1-3]

Use for:

- Major trauma patients for the first 7 days of nutrition support.
- Moderately malnourished patients undergoing major elective procedures of the esophagus, stomach, pancreas, hepatobiliary tree or abdominal-perineal resection

- Severely malnourished patients (pre-albumin < 10gm/dl) undergoing large bowel resection.
- Prolonged starvation > 6 days.
- High output distal small bowel fistula (>500 mL output).
- Burn patients.

2. Semi-elemental/elemental enteral formulas (may contain some fiber, moderate protein, and may be supplemented with Omega-3 fatty acids and/or probiotics). Semi-elemental and elemental formulas allow for ease of digestion/absorption. (E.g., Vital®, Vital 1.2 AF®, Vital 1.5®, Peptamen®, Peptamen 1.5®, Peptamen AF® are semi-elemental; Vivonex®, Vital HN®). Use for:
   - Proven intolerance to the first formula used
   - Persistent, severe diarrhea > 48hrs
   - Pancreatic or duodenal injury
   - Moderate distention > 24hrs
   - Short bowel syndrome
   - At discretion of attending physician
3. Polymeric, fiber free formula (E.g., Osmolite®1.0, 1.2, 1.5; Nutren® 1.0, 1.5,)—isotonic enteral feed with long-chain proteins, carbohydrates and a normal fat content. Use for:
   - Patients with a moderate protein need, normal digestive and absorptive capacity of the GI tract.
4. Polymeric with mixed fiber formula (Jevity 1.0, 1.2, 1.5, Fibersource HN, Nutren 1.0 Fiber, Nutrisource Fiber) added fiber content to promote more formed stool. Use for:
   - Stable, long term patients and those requiring a bowel regimen (e.g., paraplegics)
5. Other formulas include:
   - Isosource 1.5—high protein, high calorie, fiber containing formula with 1.5 kcal/ml to limit volume.
   - Nepro— volume concentrated (1.8 kcal/mL), lower in K+, Mg, Phos therapeutic nutrition with mixed fiber for patients on dialysis
   - Promote, Replete: High protein, polymeric formula, 1.0 kcal/mL. Appropriate for use in patients who tolerate a standard formula but require additional protein and do not need a volume concentrated product.
6. Additional fiber source: Use if additional fiber is needed for stool management, use the soluble variety (e.g., Nutrisource Fiber ® or equivalent.)
7. Additional protein source: Use if additional protein is needed when calorie needs are already being met by the enteral formula (ex: Beneprotein®, ProMod®, ProStat®). Content of protein varies depending on protein source used.

ENTERAL NUTRITION INITIATION AND ADVANCEMENT

VOLUME-BASED AND TOP-DOWN FEEDING PROTOCOLS

Among the many challenges to the delivery of a “goal” dose of enteral calories is the cessation of tube-feeding for procedures, patient “intolerance,” tube dislodgment, diarrhea, transfers, imaging, or other common ICU events. Improved delivery of total caloric goals has consistently been demonstrated through the use of a protocolized approach that aims to minimize interruptions and to empower the bedside caregiver (ICU nurse) to

make adjustments to ensure that caloric goals are met. A "volume-based" protocol targets a daily volume of enteral feeding rather than an hourly rate, and allows adjustments in the infusion rate or additional boluses to make up for volume lost when enteral feeds are held or interrupted.[1] When initiating and advancing enteral nutrition the following is recommended:

1. Start enteral tube feed with full strength formula at 20 ml/hour.
2. Increase rate by 20 ml/hour every 6-8 hours to goal rate if low risk for intolerance
3. If high risk for enteral feed intolerance, open abdomen, or known severe ileus, maintain trophic rate (20-30 ml/hr) for first 24 hours, then advance if well tolerated.
4. For BURN and HEAD injured patients with no abdominal trauma or other contraindications, advance 20 ml every 4 hours to goal rate.

NOTE: *When a patient is transferred from one level of care to the next in a rapid fashion (e.g., Forward Operating Base (FOB) to Role 3 to Role 4 (e.g., Landstuhl Regional Medical Center (LRMC)), it is difficult to monitor feeding tolerance during AE or Critical Care Air Transport Team (CCATT) evacuation. It may be best to hold initiation of feeds until patient will be at one location for at least 24 hours. The risk of aspiration in an awake patient or intolerance in an intubated patient is real and necessitates appropriate repeated examinations until feeding tolerance is well established prior to any flights.*

GLUTAMINE

In general, glutamine supplementation should not be utilized in the critically ill, including the critically ill combat trauma patient. This represents a major change from the previous CPG.[3] Rationale in favor of glutamine supplementation includes that critically ill patients often have decreased glutamine levels upon ICU admission, low plasma glutamine is associated with increased mortality and there are data to suggest that glutamine supplementation may reduce infections complications.[1,2,13-15] However, recent evidence indicates that glutamine supplementation significantly increases mortality rates in the critically ill, and particularly those with significant organ dysfunction syndromes.[14-16] The role of glutamine supplementation in trauma and burn patients is less clear. Available evidence regarding the benefits of glutamine supplementation in trauma patients is conflicting and a recent meta-analysis regarding enteral glutamine supplementation in trauma patients found no mortality benefit, and a trend towards decreased infectious morbidity.[16] We recommend against enteral or parenteral glutamine supplementation in critically ill combat trauma patients. The only population in which glutamine supplementation should be considered is the patient with isolated burn injury and no evidence of sepsis or multiple organ dysfunction.[1,16,17] Results of a large multi-center randomized trial (RE-ENERGIZE) are pending and will further guide the use of glutamine supplementation in the burn population once they are available.

ENTERAL SUPPLEMENTATION FOR THOSE PATIENTS TOLERATING A DIET

Many traumatically injured patients can tolerate a regular diet. For various reasons, however, patients may be subjected to frequent holding of oral intake for procedures, recovery periods after procedures, decreased appetite due to medications, etc. Supplementation drinks when a patient is eating can help bridge some of the caloric deficits and provide nutritional therapeutic benefits missed during the time-limited periods of inadequate intake.

- Recommended high-protein drinks (e.g., Ensure Plus®, Boost Plus®, Impact© Advanced Recovery™, or equivalent) can be administrated at 0.5–1.0 L per day (2–4 drinks) in addition to meals.

- There is no evidence of benefit of routine enteral supplementation in nutritionally low risk patients with intermittent brief (<48 hours) periods of NPO status.
- For moderate and high nutritional risk patients or pre-existing malnutrition, supplemental oral nutritional intake between NPO periods should be maximized and TPN considered if oral intake is inadequate or evidence of worsening nutritional parameters (e.g., weight loss, decline in pre-albumin, muscle loss).

GENERAL CONSIDERATIONS (GASTRIC FEEDS)

General considerations for patients receiving gastric feeds[1]:

1. Gastric feeds may be necessary to initiate early enteral nutrition but are highly discouraged in the combat trauma patient population during the period of rapid transport to CONUS.
2. If the clinical scenario warrants consideration of gastric feeding, it must be discussed with the attending trauma surgeon and coordinated among the entire multidisciplinary team.
3. Use of pro-kinetic agents to maximize tolerance to enteral feeding should be attempted before cessation of enteral feeding.
4. Gastric residual volumes (GRV) may be utilized, but feeding should not be halted for GRV of less than 500 cc.

GENERAL CONSIDERATIONS (JEJUNAL FEED)

General considerations for patients receiving enteral nutrition into the jejunum:

1. Maintain head of bed > 30 degrees at all times or in reverse Trendelenburg position if spine not cleared.
2. Obtain portable abdominal X-ray within12 hours of any aeromedical movement or transfer to confirm feeding tube location is within jejunum.
3. Enteral nutrition administered into the jejunum (past the ligament of Treitz) does NOT need to be stopped prior to going to the operating room, diagnostic tests, CCATT/AE transport, lying flat for procedures, etc.
4. Keep OG tube on intermittent low wall suction while initiating and advancing tube feeds via NJFT.

NJFT MAINTENANCE

1. Due to the size (8-12F) of the NJFTs, meticulous care is needed to prevent clogging of tubes. This is easily managed by flushing the tubes every 2 hours, and BEFORE and AFTER all medications given.
2. Clogging is due to either lining of the NJFT with a build-up of tube feeds or inappropriate medications given down the tube.
3. The volume of the tube is so small that no amount of pancreatic enzymes, bicarbonate, cola, etc. is effective to maintain patency for any extended period of time. Prevention of the buildup is essential to ensure a functioning tube.
4. Recommend flush feeding tube with 20 ml water (may also use pre-filled NS syringes) every two hours. Flush an additional 20 ml BEFORE and AFTER all medications are given. The volume may be increased if patient's condition and fluid requirements dictate.

5. For patients who are estimated to require prolonged enteral feeding (>4 weeks) or who are unable to tolerate or maintain a nasoenteric tube, placement of a surgical feeding tube is strongly encouraged if no absolute contraindication is present. For patients requiring prolonged enteral feeding access a gastrostomy tube is preferred over a jejunostomy for ease of management, routine care, and conversion to a simplified bolus tube-feeding regimen.

GENERAL CONSIDERATIONS (PARENTERAL NUTRITION)

1. TPN is generally unavailable in a combat zone.
2. Only utilize TPN when enteral nutrition is not possible or is inadequate to meet the minimal estimated caloric requirements.[1]
3. General initial TPN orders: 20-25 kcals/kg. Initial Dextrose of 150 g if diabetic, 200 g if not diabetic. Increase by 50 g/day if good glycemic control. Glucose infusion rate of 2-3 mg/kg/min initially. IV-Lipids of no more than 1 g/kg/d. Hold IV lipids if TG > 400 mg/dL. Provide trace elements only 1-2x/wk if total bilirubin is > 4 mg/dL.
4. Ensure patient has a clean, dedicated central line or peripherally-inserted central catheter (PICC) for administration of TPN.
5. A 0.2 micron in-line filter should be used with non-lipid containing TPN, and a 1.2 micron filter used with any lipid-containing TPN.

MEDICATION CONSIDERATIONS

INOTROPIC AGENTS (E.G., DOBUTAMINE, MILRINONE)

No change to feeding plan recommended. Advance per feeding protocol.

PARALYTICS, VASOACTIVE AGENTS

(Includes but not limited to: e.g., vasopressin > 0.04 units/min, dopamine > 10 mcg/kg/min, norepinephrine > 5 mcg/min, phenylephrine > 50mcg/min, any epinephrine)

1. Elemental formula at 20 ml/hr – do not advance.
2. Consider TPN starting post injury day number 7 if enteral feeds are not tolerated or not tolerated at the goal rate.
3. Consider early initiation of TPN in high nutritional risk score or pre-existing malnutrition patients.
4. Hold enteral feeding if adding vasopressor, increasing dosages of vasopressors, or persistent MAP < 60 mmHg.

LABORATORY EVALUATION

1. Obtain a pre-albumin every Monday for those with ICU stays greater than 7 days.
2. Obtain liver function tests (LFTs) and lipid panels at baseline and every Monday for those on TPN.

ENTERAL NUTRITION INTOLERANCE MANAGEMENT

(See Appendix A)

VOMITING

1. If no OG/NG tube in position, place one and initiate low wall suction.
2. Check existing OG/NG tube function and placement location.
3. If OG/NG tube is in proper position and functional, decrease tube feed rate by 50% and notify physician for further evaluation and work up.
4. Ensure patient is having normal bowel elimination.
5. If the patient is receiving gastric enteral feeding, consider placing the feeding tube post-pyloric.

ABDOMINAL DISTENSION (MILD TO MODERATE)

1. Perform history and physical exam.
2. Maintain current tube feed rate and do not advance.
3. Obtain portable abdominal x-ray to assess for small bowel obstruction or ileus.
4. Ensure patient is on bowel regimen to avoid constipation.
5. If distention persists >24hrs with no contraindication for continued tube feeds, switch to elemental formula.
6. If feeding while the patient is on low-dose vasopressors, any increase in distention should prompt holding tube feeds and consideration of bowel ischemia.

SEVERE

1. Perform history and physical exam.
2. Stop tube feed infusion.
3. Monitor fluid status.
4. Consider workup—CBC, lactate, ABG, Chem7, KUB, CT scan abdomen.
5. Check bladder pressure.

DIARRHEA

1. If the patient develops Moderate (3–4 times/24 hrs or 400–600ml/24hrs) to severe diarrhea (>4 times/24hrs or > 600ml/24hrs) consider the following:
2. Review medication record for possible causes of new onset diarrhea.
3. Obtain abdominal x-ray to evaluate feeding tube location.
4. Consider working up patient for Clostridium difficile (C. diff.) infection. If evidence of C. diff. infection, treat with oral metronidazole or oral Vancomycin depending on severity. If utilized, antidiarrheal

medications should be administered with great caution in the patient with C. diff. and should only be considered in the patient with a controlled or improving C. diff. infection.

5. Monitor fluid and electrolyte status.
6. Consider starting a soluble fiber supplement (e.g., guar gum, provide 1 pkg BID, increase to 1 pkg QID if stool consistency does not improve in 2-3 days).
7. If there is no evidence of C. diff. infection, consider giving 2 mg loperamide after each loose stool. An alternative is codeine 15 mg.

HIGH OG/NG TUBE OUTPUT

(> 1200 ml/24 hrs) with OG/NG tube to continuous suction and feeding via NJFT.

1. Stop tube feeds.
2. Obtain abdominal x-ray to determine location of OG/NG tube and NJFT.
    a. Verify OG/NG tube is in the stomach. If tube is past pylorus, pull it back into stomach and resume tube feeds at previous rate.
    b. Verify NJFT is in correct position. If NJFT is in the stomach take appropriate action to move the tube to the appropriate position. If NJFT is in the correct position, decrease tube feeds by 50% and assess patient's overall condition.
3. Check NG/OG tube aspirate for glucose testing in lab.
    c. If glucose > 110, hold tube feeds for 12 hours and re-evaluate.
    d. If glucose negative, resume tube feeds at 50% previous rate.

INCREASED GASTRIC RESIDUAL VOLUMES (GRV)

(With gastric or post-pyloric feeding)

1. If feeding through OG/NG tube, or if additional OG/NG tube in place (NJFT or post-pyloric feeding tube) check gastric residuals every 4-8 hours.
2. Ensure no evidence of new ileus (i.e. lack of bowel regimen, electrolyte abnormalities, recent abdominal operation, abdominal compartment syndrome, C. diff infection etc.) or bowel obstruction.
3. Re-infuse the entire gastric aspirate or administer an equivalent volume of ½ normal saline.
4. If GRV > 300 ml on two consecutive checks, notify physician.
5. Start Erythromycin 250 mg IV or oral every 6 hours or metoclopramide 10 mg IV every 6 hours and continue every 4 hour residual checks.
6. Hold enteral feeds only when ordered by physician.

BOWEL REGIMEN

Those patients at high risk for acute constipation should be started on a bowel regimen. If a patient is receiving tube feeds and has less than one Bowel Movement (BM) every two days, they should be started on the bowel care protocol. A bowel care protocol also may be started empirically with initiation of enteral nutrition in patients know to be at risk for constipation.

ACUTE CONSTIPATION

Inclusion criteria for patients at high risk for acute constipation:

- Opioids
- Immobility
- Altered diet and fluid intake
- Stress
- History of constipation

RELATIVE CONTRAINDICATIONS

- Rectal surgery
- Abdominal pain
- Allergy to bowel regimen medications
- Neutropenia (ANC < 1000/mm^3)
- Thrombocytopenia (platelets < 30,000)

ABSOLUTE CONTRAINDICATIONS

Suspected or confirmed bowel obstruction

NOTE: *If patient has had one BM every two days, patient is at Stage One or under observation only.*

STAGE ONE

(If no bowel movement for 48 hours)

Patient assessment and rectal exam

1. Impacted: Manually dis-impact; give soap suds enema once OR Bisacodyl 10 mg suppository once daily
2. Not impacted: Docusate 100 mg PO or NJFT q 8 hours and Senna 1 tab PO or 5ml via NJFT every am
3. If no BM or very small amounts in 24 hours following initiation of Stage One, proceed to Stage Two.

STAGE TWO

1. Add Bisacodyl 10 mg supp once daily, hold if stooling and continue with Stage One regimen.
2. If no BM or very small amounts within 24 hours, proceed to Stage Three.
3. If patient develops loose stools or diarrhea, return to Stage One.

STAGE THREE

1. Add Milk of Magnesia 30 ml PO every 6 hours or Miralax 17 grams PO/NJFT twice daily until BM, then stop (avoid Milk of Magnesia if renal insufficiency is present). Return to Stage Two.
2. If no BM in 24 hours or very small amounts, proceed to Stage Four.
3. If patient develops loose stools or diarrhea, return to Stage One.

STAGE FOUR

1. Call and notify MD.
2. Obtain an abdominal x-ray.
3. Clarify continued therapy for bowel care.

FECAL MANAGEMENT SYSTEM

For patients requiring the use of Fecal Management System (FMS) for wound care and/or stool management, please refer to manufacturer's instructions for use. FMS should only be used with the approval of the patient's attending surgeon.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All ICU patients

INTENT (EXPECTED OUTCOMES)

Enteral feeding access is established or oral diet initiated within 24 hours of admission to the Role 3 or higher Medical Treatment Facility (or contraindication documented).

PERFORMANCE/ADHERENCE METRICS

Number and percentage of patients in the population of interest who have enteral access established or oral diet initiated within 24 hours of admission to the Role 3 or higher Medical Treatment Facility.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.
The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: ADULT PARENTERAL NUTRITION ORDER FORM

DIRECTIONS: The provider will DATE, TIME, and SIGN each order or set of orders recorded. Only one order is allowed per line. Nursing will list the time the new order(s) are noted and initial in the column provided. Orders completed during the shift in which they were written do not require recopying. They may be signed off, as completed, in the far right column.

ORDER NUMBER	PROVIDER: DATE, TIME, & SIGN EACH PAGE OF ORDERS
	ADULT PARENTERAL NUTRITION ORDER FORM

Date:	Time:	Service:	Allergies:

Check and complete appropriate orders, where indicated. All order amounts are PER 24 HOURS

1. Access Route: ☐ Central ☐ Peripheral (must be less than 900 mOsm/liter; intended for short term use only)

2. Rate of Infusion: ☐ Infuse over 24 hours (rate determined by pharmacy, based on final volume
☐ Cyclic Infuse from _____ to _____

3. Base Formula:

Nutrients	Total Volume	Amino Acids	Dextrose (Carbohydrate, CHO)
☐ Premix Central Formula withOUT electrolytes	1000 mL	8.5% 500 mL (42.5 grams protein)	50% 500 mL (250 grams dextrose)
☐ Custom Parenteral Formulation	_____mL (not include lipids)	Please use 500 mL increments, where clinically appropriate ☐ 8.5% _____mL (42.5 grams protein/ 500 mL) ☐ 10% _____mL (50 grams protein/ 500 mL) ☐ 15% _____mL (75 grams protein/ 500 mL)	☐ 25% _____mL (125 grams dextrose/ 500 mL) ☐ 50% _____mL (125 grams dextrose/ 500 mL) ☐ 70% _____mL (125 grams dextrose/ 500 mL)

4. Lipids: 20% fat emulsion (2 kcal/mL) ☐ 500 mL ☐ 250 mL Infuse IV over 12 hours ☐ every day ☐ every __days

5. Electrolytes and Additives (per 24 hr bag)

Standard Electrolyte Package		Customized Electrolytes	Additives (per 24 hr bag)
Sodium 35mEq Potassium 20 mEq, Chloride 35mEq Acetate 29.5meq Magnesium 5 mEq Calcium 4.5mEq (Hospira TPN Lytes 20 mL) *Does not contain phosphate*	_____ packages (usual 1-2/day)	Sodium chloride _____mEq Sodium acetate _____mEq Potassium chloride _____mEq Potassium acetate _____mEq Sodium phosphate _____mMol Potassium phosphate _____mMol Magnesium sulfate _____mEq Calcium Gluconate _____mEq	☐ Trace Elements 1 mL ☐ Multi-Vitamins 10 mL ☐ Ascorbic acid _____ mg ☐ Ranitidine _____mg ☐ Insulin _____units ☐ On an insulin infusion ☐ Phytonadione 10mg every Monday ☐ Other: _____

NOTE: *Maximum calcium:phosphate ratio = 50 (see reverse for calculation)*

6. Additional Orders

a. Labs
- ☐ Baseline: basic metabolic panel (BMP), albumin, liver function panel (if not done in last 24 hours)
- ☐ Daily: BMP; Every other day: Calcium, magnesium, phosphate
- ☐ Weekly: albumin, triglycerides
- ☐ Blood glucose (BG) every 6 hours; discontinue if BG < 150 x 4; call MD for >150 for two sequential checks if not ordered for insulin

b. For initial order (first bag): Please notify dietician and pharmacist, to complete patient assessment.

c. Strict I/O's, daily weight

d. Infuse total parenteral nutrition (TPN) thru a dedicated line.

e. Use an in-line filter (0.2 micron filter for non lipid containing and 1.2 micron filter for lipid containing TPN)

f. For discontinuation of the TPN, cut the rate by 50% for 60 minutes, then stop (to prevent hypoglycemia)

PATIENT IDENTIFICATION	Signature Date/Time (Printed Name)

LRMC ADULT PARENTERAL NUTRITION ORDER FORM	Nursing Unit	Room No.	Bed No.	Page No. 1

MEDCOM FORM 688-R (MCHO) PREVIOUS EDITIONS ARE OBSOLETE MCEUL OP-347(rev) 2 Mar 99 MRRC apprvl, 4 Feb 99

GUIDELINES FOR ORDERING ADULT PARENTERAL NUTRITION

SUBSTRATES	KCAL SUPPLIED	COMMENTS
DEXTROSE (Carbohydrate/CHO)	3.4 kcal/one gram dextrose	CHO tolerance ranges from 2-5 mg/kg/minute. Maximum CHO utilization/tolerance average is 4 mg/kg/minute: 4 x (weight in kg) x 1.44 = grams CHO/day
AMINO ACIDS (Protein/AA)	4.0 kcal/one gram protein	6.25 gm protein per 1 gm Nitrogen. Dosage depends on degree of stress/injury, renal/liver function
LIPID (Fat)	9.0 kcal/ one gram fat (20% = 2.0 kcal/mL) (Propofol = 1.1 kcal/mL)	Not to exceed 30% of total kcals or 0.8 grams fat/kg

ADDITIVES

Electrolytes	Normal Range of Daily Requirements	Recommended Maximum per Liter
Calcium*	10-15 mEq/day (5 mEq/liter)	(up to) 10 mEq (when combined with P)
Magnesium	8-24 mEq/day (5 mEq/liter)	(up to) 15 mEq
Potassium	90-240 mEq/day (20-50 mEq/liter)	(up to) 80 mEq
Sodium	60-150 mEq/day (20-50 mEq/liter)	Wide Range
Acetate	80-120 mEq/day (30-50 mEq/liter)	Wide Range
Chloride	60-150 mEq/day (20-50 mEq/liter)	Wide Range
Phosphorus**	30-50 mMol/day (10-15 mMol/liter)	(up to) 30 mMol (when combined with Ca)

*Calcium gluconate provides approximately 5 mEq Ca/gram

**Potassium phosphate provides 0.68 mMol phosphate/1 mEq K; sodium phosphate provides 0.75 mMol phosphate/1 mEq Na

Vitamins:	One Multi-Vitamin package (10 mL) provides the following:		
	Retinol (A) 3300 units (1 mg) Ergocalciferol (D) 200 units(5 mcg) Tocopherol (E) 10 units (10 mcg) Phytonadione (K) 150 mcg	Ascorbic Acid 200 mg Riboflavin (B2) 3.6 mg Thiamine (B1) 6 mg Pyridoxine (B6) 6 mg Pantothenic acid 15mg Biotin 60 mcg	Folic acid 600 mcg Cyanocobalamin (B12) 5 mcg Niacinamide 40 mg
Trace Elements:	One dose of 1 mL should be administered daily except with renal failure and/or liver dysfunction.		
	One trace minerals package provides the following:		
	Zinc 5 mg ** Copper 1 mg Manganese 0.5 mg Chromium 10 mcg		
	Additional supplementation of trace elements may be required based upon degree of stress, injury or disease state		
	*Additional 2.0 mg Zinc/day in acute catabolism; 12.2 mg/L small bowel fluid losses; 17 mg/kg stool or ileostomy output		
	Selenium should be supplemented with long-term parenteral nutrition (60 micrograms/day).		
Regular Insulin:	It is reccommended that insulin be provided on a sliding scale requirement or by an insulin drip. If added to parentral nutrition orders, it should be in amounts no less than 10 units per liter and only to the nearest 5 or 10 units per liter.		
Calcium:	**Phosphate calculation** Ca^{+2} in each liter (mEq) + [2 x PO_4 in each liter (mMol)] must be less than or equal to 50, to prevent precipitation of $CaPO_4$		

GENERAL REQUIREMENTS

Kcals:	25-35 kcal/kg dry weight 25-30 kcal/kg dry weight for ventilated pts	
Protein:	1.0-1.5 grams protein/kg 1.5-2.0 grams protein/kg in trauma/head injury In obese pts: use IBW to calculate protein needs	
Fluid:	30-35 mL/kg	

OSMOLARITY (mOsm) for PPN

CHO	mOsm/L	Protein	mOsm/L	Fat	mOsm/L
$D_{10}W$	505	AA 8.5%	890	20% lipids	260
$D_{20}W$	1010	AA 10%	1000		
$D_{30}W$	1515	AA 15%	1500		
Maximum recommended mOsm for PPN = 900mOsm/liter (maximum example: D20W 500 mL and AA 8.5% 500 mL)					

APPENDIX B: ENTERAL NUTRITION POCKET REFERENCE GUIDE

FORMULA SELECTION

Critical Care enteral formulas
(High protein/volume concentrated, may contain immunonutrients)

1. Patients sustaining major trauma receive immune-enhancing diet for 10 days (except BURN patients):
2. Non-trauma patients who the attending surgeon believes to be at risk for major septic morbidity, such as:
   - Moderately malnourished patients) undergoing major elective procedures of the esophagus, stomach, pancreas (with or without duodenum), hepatobiliary tree or abdominal-perineal resection.
   - Severely malnourished patients, or undergoing colonic resection
3. Prolonged starvation > 5 days
4. High output distal colonic fistula

Elemental Formulas
Patients who have:

1. Proven intolerance to the first formula used
2. Persistent, severe diarrhea > 48hrs
3. Pancreatic or duodenal injury
4. Moderate distention > 24hrs
5. Short bowel syndrome
6. At the discretion of the attending physician.

Polymeric Formula
Patients who do not meet the criteria for immune-enhancing diets but have normal digestive and absorptive capacity of the GI tract

TOTAL PARENTERAL NUTRITION
Indications include:

- Massive small bowel resection refractory to enteral feeds
- High output fistula after failure of elemental diet
- Unable to meet >60% needs enterally by day ICU day #5

FEEDING PROTOCOL

After resuscitation complete, start full strength formula at 20 ml/hr advance as follows:

- Increase by 20 ml/hr every 8 hours until the targeted goal is reached.
- In burn/head trauma patients with no abdominal injury, increase every 4 hours until the targeted goal is reached.
- Do not stop enteral feedings for procedures to include trips to OR, CT scanner or AE (for tubes inserted beyond the ligament of Treitz).

ENERGY/PROTEIN REQUIREMENTS

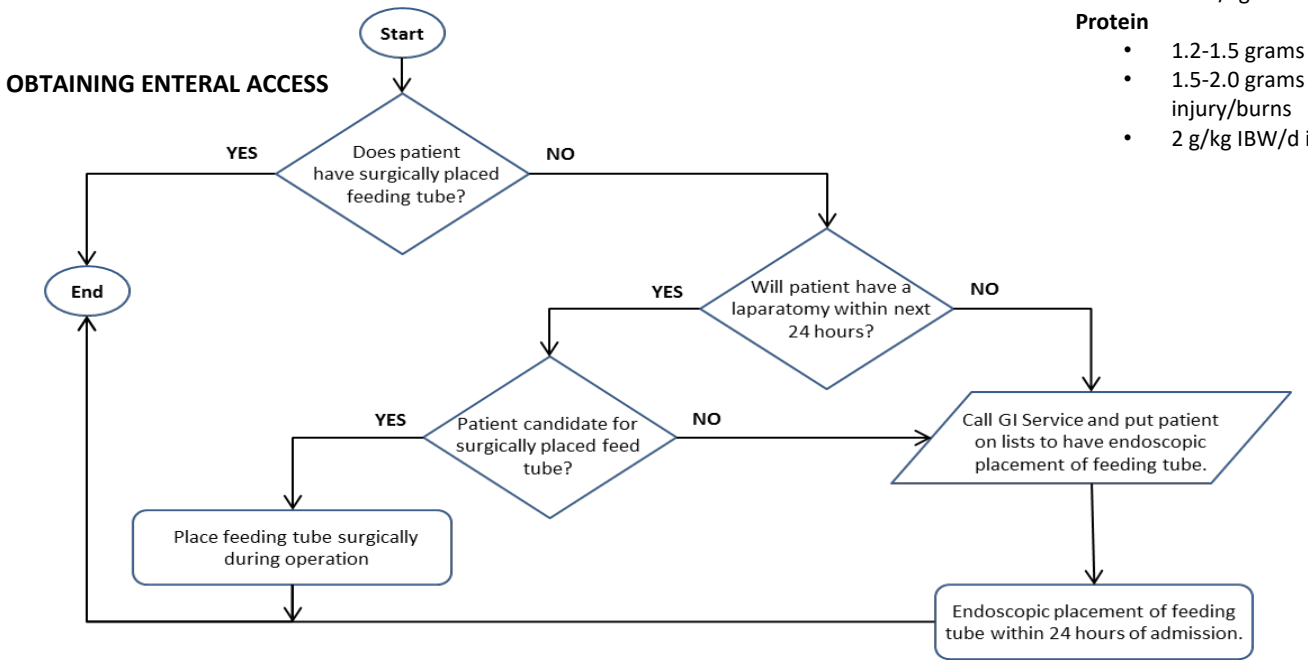
Kcals (total)

- 25-35 kcal/kg dry weight for stress/trauma/burns
- 20-25 kcal/kg dry weight for ventilated pts
- 11-14 kcals/kg actual body wt or 22-25 kcals/kg IBW if obese (BMI > 30)

Protein

- 1.2-1.5 grams protein/kg
- 1.5-2.0 grams protein/kg in trauma/head injury/burns
- 2 g/kg IBW/d in obese patients

OBTAINING ENTERAL ACCESS



Start
Does patient have surgically placed feeding tube?
YES
NO
End
Will patient have a laparatomy within next 24 hours?
YES
NO
Patient candidate for surgically placed feed tube?
YES
NO
Call GI Service and put patient on lists to have endoscopic placement of feeding tube.
Place feeding tube surgically during operation
Endoscopic placement of feeding tube within 24 hours of admission.

APPENDIX C: MANAGING ENTERAL FEEDING INTOLERANCE

MANAGING INTOLERANCE			
Indicator	**Severity**	**Definition**	**Treatment**
Vomiting	(Occurrence)	Any	• If no OG then place OG and start intermittent low wall suction • Check existing OG function/placement • IF OG placement correct, decrease TF infusion rate by 50% and call MD
Abdominal distention and/or cramping or tenderness (if detectable)	Mild	History and/or Physical exam	• Maintain TF infusion rate
	Moderate	History and/or Physical exam	• Maintain TF infusion. Do not advance • Order AP supine KUB x-ray • assess for small bowel obstruction If moderate distension for > 24 hrs, switch to elemental formula
	Severe	History and/or Physical exam	• Stop TF infusion • Monitor fluid status • Consider CBC, lactate, ABG, Chem7, CT scan abdomen • Check bladder pressure
Diarrhea	Mild	1-2 x /24 hr or 200-400 ml/24 hr	• Increase TF infusion rate per protocol
	Moderate	3-4 x / 24 hr or 400-600 ml/24 hr	• Maintain TF infusion rate. Do not advance • Evaluate patient for Clostridium Difficile per local hospital protocol • Consider soluble fiber (Nutrisource Fiber ®, 1 pkg BID, increase to 1 pkg QID). • Consider probiotics if not contraindicated.
	Severe	>4 x / 24 hr or >600 ml / 24 hr	• Decrease TF infusion rate by 50% • Review MAR: note antibiotic, bowel regimen, prokinetics, elixirs • Evaluate patient for Clostridium Difficile per local hospital protocol • If c. diff positive then treat appropriately and hold antidiarrheals for 48 hrs. • If c.diff negative give 2 mg loperamide after each loose stool • Order AP supine KUB x-ray to evaluate location of feeding tube • Consider switching to elemental formula • Monitor fluid and electrolyte status
High NG output	measured	>1200 ml / 12 hr	• Stop TF • Order AP supine KUB to evaluate location of OG and feeding tube ○ If OG past pylorus, pull back into stomach and resume tube feeds @ previous rate ○ If NJ in the stomach, consult GI to replace ○ If both tubes in correct position, decrease tube feed rate by 50% assess patient entirely • Check OG aspirate for glucose by lab ○ if glucose >110, hold TF, reassess in 12 hours ○ If OG aspirate glucose negative, resume TF at 50% previous rate
Medication Considerations	Inotropic agents e.g.,Dobutamine, Milrinone		• Advance feeding per protocol
	Paralytics and vasoactive agents: any paralytic continuous infusion, vasopressin >0.04units/min Dopamine > 10mcg/kg/min, Norepinephrine > 5mcg/min Phenylephrine > 50mcg/min, any epinephrine		• Elemental formula at 20mL/hr. Do not advance • Hold modular protein (Beneprotein/Prostat). • Consider concurrent TPN starting ICU day #7

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Ocular Evaluation and Disposition after Suspected Laser Exposure (CPG ID:79)

This CPG provides information and instructions for medical providers responsible for service members following a suspected directed energy exposure involving the visual system

INTRODUCTION

This Clinical Practice Guideline provides information and instructions for medical providers responsible for Service members following a suspected directed energy (DE) exposure involving the visual system. (Consider: There is little experience in the general medical community with DE and having a high index of suspicious for this type of injury is important. If a DE exposure is suspected – early consultation with ocular care providers is important as is having a full understanding of the physiologic and anatomic effects of this type of injury. Ocular DE injury can result in mission compromise and pose safety hazards to the individual and the unit.) These suspected exposures, presumed caused by a laser or other intense bright light source, can compromise the ability to execute mission essential functions. For the purposes of this guideline, the term laser will also include any light source, visible or invisible, capable of resulting in potential injury. The intent of this guideline is to provide a better understanding of this type of injury and its effects and to establish a care algorithm for first-line providers and follow-on care by eye care providers. This CPG is based on expert consensus because there is little available data on this type of injury. Specifically, it includes the key elements of a Service member's history, examination, disposition, and medical record coding following potential exposures. Service and unit-specific reporting procedures for exposures and possible injuries are also included. Early recognition and treatment of potential injuries is essential to maintain optimal visual performance. In addition, timely reporting is essential to assess the operational impact of these exposures/injuries.

CLINICAL SCENARIOS

1. An aircrew making a final approach is exposed to a laser source, leading to temporary flash blindness. Spatial awareness and situational awareness is effected, compromising actions during critical operations. The symptoms resolve without functional or anatomic evidence of damage.

2. A mounted service member employs an escalation of force visible laser during operations. The beam is reflected of the turret mirror resulting in close proximity exposure. Central vision is immediately compromised. Evaluation shows decreased vision and retinal edema. This results in a central retinal scar and loss of vision.

BACKGROUND

Lasers emit nonionizing radiation in the ultraviolet, visible, and infrared portions of the electromagnetic spectrum. When the eye is exposed to this energy, temporary disruption of visual function or permanent injury may occur.[1] Lasers available for wide scale commercial purchase that emit at visible wavelengths (including red, green, and blue) have been increasingly reported in laser strikes on commercial aircraft. These laser strikes on commercial aircraft have been reported most frequently during takeoff and landing.[2] A review of these civilian aircraft incidents found that while these laser strikes have not resulted in any documented permanent changes in visual functional or structural damage to the eyes, they have been documented to cause immediate visual effects, including flash blindness, glare, and startle that can interfere with critical functions on board the aircraft. Based on reports by civilian pilots that have been directly exposed, recovery of optimal visual function can take from seconds to minutes. However, alterations in visual function can last from several minutes to several hours.[3]

Potential exposures of the visual system to laser threats that are present across the spectrum of military operations are more varied. Laser technology is incorporated into multiple weapons systems from both friendly and hostile forces and presents a threat of temporary visual effects or permanent injury to the eye. Most laser systems designed for military use emit at infrared wavelengths that cannot be seen by the human eye. Visible laser systems also pose a threat to military operations. A review of data from the Defense and Veterans Eye Injury and Vision Registry (DVEIVR) from 2006-2018, found 132 service members with documentation of exposure in the medical record. Of these cases reviewed, five service members found to have permanent damage compromising visual function as a result of exposure.

KEY POINTS

- Ocular exposure to directed energy in the form of lasers can acutely disrupt operational functioning.
- Permanent injury to the eyes and visual system is rare after these exposures.
- Awareness of this type of exposure is critical for all deployed providers.
- Early engagement of eye care specialist is essential to maximize recovery.
- Service members with persistent symptoms or worsening vision complaints require priority evacuation.
- Exposed Service members require comprehensive evaluation by an eye care provider as soon as possible after exposure events.
- Consistent documentation of exposures and injuries will improve treatment recommendations

EFFECTS OF EXPOSURE

Exposure of the eyes to laser energy generally leads to two categories of effects.

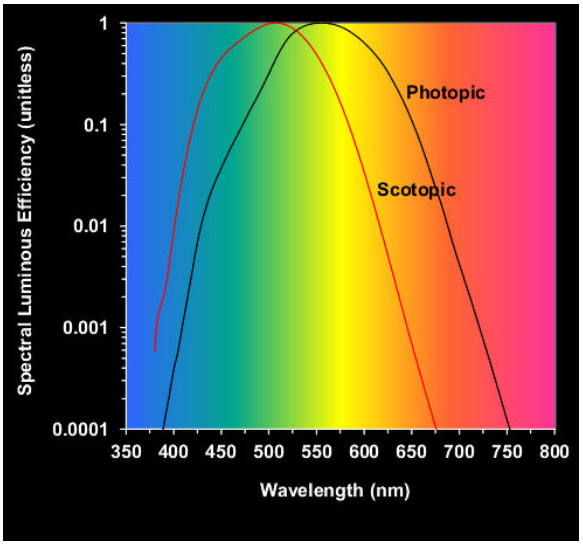
1. Visual interference effects
2. Ocular injury (persistent anatomic or visual function abnormalities)

INCIDENT WITH TEMPORARY VISUAL INTERFERENCE EFFECTS

These effects are the result of wavelengths in the visible spectrum (400-700 nm). The wavelength or color of the source is associated with the degree of immediate visual function disruption following an exposure. This is because the human eyes spectral response to color varies across the visible spectrum. We see the color green much better than blue or red. Our response to color even varies with lighting conditions. The vision we use under well-lit, daytime conditions is called photopic vision and under low-light levels, nighttime conditions is called scotopic vision. For example, green light is capable of producing visual function disruption with less relative power than red light at similar distances. Effects include temporary flashblindness, afterimages, and glare. They also include startle, distraction, and disruption, effects that may not directly degrade vision but may have an effect on human performance. These effects are more pronounced when a person is exposed at night or in a dark environment.

Figure 1. Spectral Response of the Eye

The standard photopic and scotopic sensitivities of the eye as defined by the Commission internationale de l'éclairage (CIE) or International Commission on Illumination are shown and demonstrate the peak sensitivity to green wavelengths. Note the logarithmic scale of the y-axis.



Visual interference effects include:

1. **Flash blindness** - A visual interference effect that persists as an afterimage after the source of illumination has ceased.
2. **Glare** – An obscuration of an object in a person's field of vision due to a bright light source located near the same line of sight.
3. **Afterimage** - A transient image that persists in one's visual field after a bright source of illumination has been removed.
4. **Startle** – The involuntary reaction to an unexpected event that alters mental, physical, and visual activities and diverts selected attention away from the normal primary tasks of an individual. The startle response can be broken into four specific categories: Distraction, Disruption, Disorientation, and Operational Incapacitation.
    - **Distraction** – Momentary attention shift from primary tasks due to sudden exposure to a bright light source. This effect may not be readily identified by the Service member and should be asked specifically.
    - **Disruption** – Interference or interruption of critical tasks or task sequences that extend the shift of attention from primary tasks requiring selective attention.
    - **Disorientation** – Losing perspective in the relationship between the direction of travel and surroundings. Can include loss of both spatial orientation and situational awareness. Disorientation can occur simultaneously with distraction, disruption, and startle.
    - **Operational Incapacitation** – An individual's loss of spatial orientation and loss of situational awareness in reference to the outside world. In the case of aviation, a pilot that becomes

operationally incapacitated should immediately transfer control of their aircraft because they can no longer reliably discern or control the aircraft.

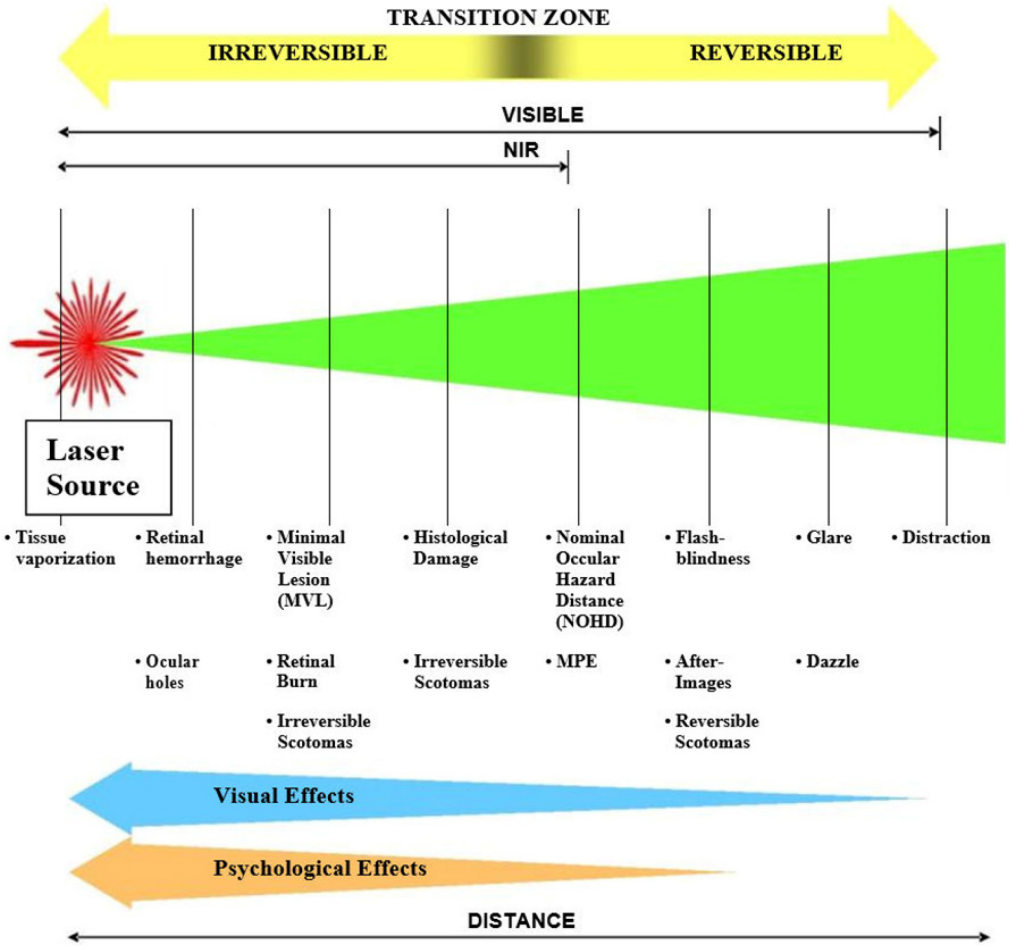
The natural aversion response to bright light sources limits exposure to visible wavelength lasers to about 0.25 seconds. Although exposure may be limited to a fraction of a second by your ability to blink or turn away from the offending light source it does not provide absolute protection from injury.

INCIDENT WITH SUSPECTED OCULAR INJURY

An ocular injury can result from any laser wavelength if sufficient power is delivered to the eye. The affected structure within the eye varies with wavelength. Lasers emitting in the far ultraviolet, UV-B and UV-C (180-315 nm), and far infrared, IR-B and IR-C (1400 nm – 1 mm), are absorbed by the cornea. Near ultraviolet, UV-A (315-400) wavelengths are absorbed by the lens of the eye. Visible (400-700 nm) and near infrared, IR-A (700-1400 nm) wavelengths are absorbed by the retina. The spectral region 400-1400 nm is commonly referred to as the retinal hazard region. Laser output power, or energy, is an important determinant for injury potential, as is the duration of the exposure and the exposed person's location relative to the laser source exit aperture.

Figure 2. Effects of laser and other intense/bright light exposures based on distance.

Source: AF Laser Injury Guide Book.



OPTICAL DEVICES

Vision enhancement devices, such as Night Vision Devices, provide an additional barrier between the laser and the eyes which can provide a degree of protection. However, they can be more sensitive to interference from intense light sources, both visible and non-visible wavelengths, especially compared to the unaided eye. This can cause difficulty with the device's operation and significantly affect safety.

Optical scopes, or other devices with magnifying optics, may amplify or further focus the light source, leading to more energy delivered to the eye and increased risk of injury.

EVALUATION OF SUSPECTED INJURY

All service members with a laser exposure require evaluation. The form below includes key points for documentation as well as recommended testing and intervals. Generally, service members should be evaluated at least daily until symptoms resolve or evacuation to an eye care provider is available. After evacuation out of theater frequency of follow-up is based on clinical situation, but should occur at a minimum of 1, 3, and 6 months following exposure/injury. Detailed sheets to guide the evaluation for all providers are available in Appendix A. These include sheets to guide initial providers through key history and examination elements, as well as more specialized recommendations for eye care providers. Medical documentation does not replace operational reporting as detailed below. These recommendations may be modified as new information is available through ongoing analysis of exposures and outcomes.

Use of the Laser Incident Questionnaire (Appendix B) enables both medical and operational aspects of the incident to be documented. Exposed/injured service members can expect to undergo more extensive interviews with additional medical, operational, and military intelligence personnel after treatment has been initiated.

TREATMENT & DISPOSITION

TREATMENT

Initial treatment guidance for suspected ocular injury from laser exposure is limited. Readily identifiable injuries such as corneal abrasions, hyphema or vitreous hemorrhage should be treated using current standards in coordination with an eye care provider. These guidelines can be found in the Eye Trauma: Initial Care, 28 Aug 2019 and Ocular Injuries and Vision-threatening Conditions in Prolonged Field, 01 Dec 2017. In the context of visual dysfunction, available literature suggests early treatment with non-steroidal anti-inflammatory drugs (NSAIDS) and/or systemic corticosteroid therapy.[4,5,6] Treatment of SMs with suspected ocular injury should be considered as follows (if not otherwise contraindicated):

1. **Vision 20/40 or better** but not at baseline, visual interference effects lasting more than 2-4 hours: start NSAID (indomethacin by mouth 25mg three times/day can be used if available, or ibuprofen 800mg by mouth three times/day

2. **Vision worse than 20/40**, any Amsler grid abnormalities: Consider addition of oral prednisone (0.5 to 1 mg/kg); teleconsultation with eye care provider recommended.

Evaluation by an eye care provider in theater should be obtained if operationally feasible. This decision is best made after discussion with the eye care provider. Teleconsultation for specific treatment decisions when no eye care providers is available.

Teleconsultation Services

- ADVISOR 833-238-7756; DSN 312-429-9089 (select emergency department and callers will be connected to ophthalmology) ADVISOR covers all Combatant Commands
- U.S. Air Force School of Aerospace Medicine Ophthalmology: 937-938-2675
- Naval Aerospace Medical Institute Ophthalmology: 850-452-2933; usn.pensacola.navmedotcnamefl.list.nami-ophthal@mail.mil

Asynchronous Consultation Services:

- INDOPACOM: Pacific Asychronous TeleHealth (PATH): https://path.tamc.amedd.army.mil/
- EUCOM, CENTCOM, AFRICOM, SOUTHCOM: Health Experts onLine Portal (HELP): https://help.nmcp.med.navy.mil/

***NOTE**: PATH and HELP links require establishment of an account*

Service members (SM) reporting worsening visual acuity or visual symptoms, or a change in exam findings should be considered for priority evacuation to allow for evaluation and care by an eye care provider. SMs with any visual symptoms that persist beyond 24 hours despite initial treatment should be considered for priority evacuation.

All SMs with symptomatic exposures, even those that return to baseline function, should have comprehensive evaluation by an eye care provider in theater or upon redeployment if resources are not available in theater. This post-exposure evaluation should be documented in the electronic medical record.

SMs with repeated exposures (multiple exposures over several days), should be evaluated for symptoms after each incident, and each evaluation documented and treated as an additional exposure.

DISPOSITION

Flight Surgeons

Follow Service-specific guidelines for aviation personnel; full references at end of CPG.

- United States Air Force School of Aerospace Medicine Laser Injury Guidebook
- OPNAV Instruction 5100.27B Marine Corps Order 5104.1C, Navy Laser Hazards Control Program[7]
- Army personnel should follow above guidance

***NOTE**: Aviation personnel are only to be returned to duty in accordance with Service-specific aviation guidelines from the above references and local SOPs.*

Other Forward Providers

SMs with exposures that return baseline visual function (with no new or persistent defects on Amsler grid testing, see Appendix C) within 2-4 hours may be returned to full duty without restrictions as long as the SM meets current service-specific standards. Full documentation and incident reporting is required for incidents with transient visual interference effects as well as suspected ocular injuries. Non-aviation personnel may return to duty when visual function returns to baseline and allows for effective execution of MOS-specific duties and operational requirements.

Eye care providers

1. Whenever feasible and operationally viable, obtain ultrastructural image of the retina as near to point of exposure as possible in SMs with persistent visual complaints. This will serve to further define the severity of injuries, serve as a baseline for visual recovery, and inform ongoing understanding of the spectrum of directed energy injuries as an evolving operational concern.
2. Service Members with suspected ocular injuries from laser exposure are eligible for enrollment in the DVEIVR https://vce.health.mil/Vision-Registry/Need-Access. The registry is populated using medical encounter documentation. Only unclassified details of the event should be entered into the medical record. Coding recommendations to facilitate tracking and analysis are listed below.
3. Service Members with documented retinal involvement should be referred to a vitreoretinal specialist for further evaluation.

MEDICAL CODING

The following ICD-10 coding guidance is recommended for laser exposures. Proper documentation and coding of these events allows for optimal tracking and analysis inform and evaluate treatment recommendations. Uniform and consistent medical documentation and coding is essential to proper surveillance and research efforts. This guidance is designed to standardize coding across the MHS.

Table 1. ICD-10 coding guidance for laser exposures

Diagnostic Position	Code	Comments
Principal/First listed Diagnosis	Initial symptoms (headache, blurred vision, etc.)	Allows for tracking duration/resolution of symptoms longitudinally
Second Diagnosis	Anatomic findings (burn, scar, etc.)	Allows for documentation and tracking of injuries longitudinally
Third Diagnosis	W90.2* Exposure to laser radiation	ICD-10 codes in the range V00-Y99 describe the cause of the morbidity, not the condition itself; this code allows for accurate tracking of laser exposures.
	W90.2XXA Exposure to laser radiation initial encounter	
	W90.2XXD Exposure to laser radiation subsequent encounter	
	W90.2XXS Exposure to laser radiation sequela	

INCIDENT REPORTING

1. Notify Chain of Command at the earliest level possible.
2. Notify the DoD Laser Hotline as soon as time and circumstances permit:
   - DoD Laser Hotline Toll-free: 800-473-3549 (not currently manned 24/7)
   - https://hpws.afrl.af.mil/dhp/OE/ESOHSC/laserinjury/
   - US Army Institute of Surgical Research (MCMR-SRR-O), Ocular Trauma and Vision Restoration,
   - https://usaisr.health.mil/, Trauma Clinic & Civilian Care Coordination Office (CCCO) phone 210-916-2796.
3. Notifications as outlined in the Air Force Occupational Safety and Health Standard, AFI48-139 should be made as soon as possible. Field level notification should be made to the Deployed Medical Commander and the Air Expeditionary Wing Commander. Notify the Tri Service Laser Injury Hotline (1-800-473-3549) as soon as time and circumstances permit.
4. Medical personnel can coordinate medical guidance for laser injuries from the DoD Laser/EMF Injury Hotline through the ESOH Service Center, (800) 473–3549, DSN 798–3764, commercial (937) 938–3764, or email esoh.service.center@wpafb.af.mil. Upon examination, if the medical facility suspects or confirms the over exposure, they contact the injured person's commander or supervisor.
5. For Army Aviation, Commander, U.S. Army Combat Readiness Center (CSSC–Z), Fort Rucker, AL, at DSN 558–2660/3410, commercial (334) 255–2660/3410 (24-hour phone line), FAX DSN 558–3749, commercial (334) 255–3749 or email helpdesk@crc. army.mil.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with laser eye exposure/injury.

INTENT

1. Patients in the population of interest are identified as having exposure at first role of surgical care.
2. Patients in the population of interest undergo comprehensive evaluation by an eye care provider as soon as possible after exposure events
3. Patients in the population of interest have complete documentation of type of laser injury, severity, treatment, and outcomes.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with documented comprehensive eye exam.
2. Number and percentage of patients in the population of interest with complete documentation of type of laser injury, severity, treatment, and outcomes.

DATA SOURCES

- Individual Medical Record
- DVEIVR
- DoD Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief, JTS Program Manager, and the JTS Performance Improvement Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

ACKNOWLEDGMENTS

The JTS extends a special thanks to the voting members of the JTS Committee on Surgical Combat Casualty Care for their contribution to the development and publication of this clinical practice guideline.

APPENDIX A: EVALUATION & DOCUMENTATION SHEETS FOR PROVIDERS

Laser Exposure Medical Documentation: Initial Provider Evaluation		
Patient		
Identifier		
Date of Injury		
Date of Evaluation		
History		
Element	**Description**	**Result**
Exposure description	Color, brightness and duration of light/exposure	
	Other characteristics of light (pulse/flicker)	
	Eye(s) exposed	
	Direct or reflected exposure	
	Activity/tasks at time of exposure and ability to perform tasks.	
	Optical devices in use at the time of suspected exposure (night vision devices, magnifying devices, specific laser protection devices)?	
Presenting Symptoms	Reported symptoms may include: blurred vision, headache, blind spots, shadows, eye pain, eye irritation/burning, etc.	
Time since exposure	How long ago was the exposure?	
Duration of symptoms	Seconds, minutes, hours, ongoing	
Medical/Ocular History	Previous visual function (baseline vision as available (i.e. glasses use)	
	Previous ocular history	
	History of refractive surgery	
	Current medications	
Social History	Tobacco use	
Examination		
Element	**Description**	**Result**
Laterality (OD/OS/OU)	Accomplished at every visit. Document affected eye(s)	
Visual Acuity	Accomplished at every visit. Note whether acuity was taken at near or distance, and whether acuity was accomplished with or without correction; annotate whether spectacles or contacts were used.	

Laser Exposure Medical Documentation: Initial Provider Evaluation		
Amsler grid* testing (*Appendix B*)	Accomplished at the initial visit, and at follow-up for previously documented abnormality or where new symptoms are disclosed ; document abnormalities or "normal" in each eye	
Color Vision testing	Accomplished at the Initial visit, and at follow-up for previously documented abnormality or where new symptoms are disclosed performed at follow-up if new abnormality; document abnormalities or "normal" in each eye computerized color vision testing, monocular, with red, green, blue cone testing individually preferred if available (pseudoisochromatic plates are not considered adequate for this testing, but may be used for initial screening)	
Pupils	Document size, shape, and reactivity	
External eye	Evaluate for irritation, burns, corneal opacities; Document abnormalities or "normal" in each eye	
Retinal evaluation	Accomplished at the Initial visit, and at follow-up for previously documented abnormality or where new symptoms are disclosed performed at follow-up if new abnormality; document abnormalities or "normal" in each eye	
Additional evaluation	Flight Surgeons complete additional evaluation and testing required for aviation personnel based on training and Service-specific guidelines.	

*The Amsler grid is a printed grid pattern with a central dot. It is designed to demonstrate alterations in vision near fixation (the area of highest acuity). See Appendix C for details of use.

APPENDIX B: LASER INCIDENT QUESTIONNAIRE

The following questions taken from the AFRL-SA-WP-SR-2012-0005, are designed to gather information to assist medical, operational, and intelligence personnel in analysis of laser beam exposure incidents. It should be anticipated that further questions and information will be sought as time allows. Finally, remember to call the Tri-Service Hotline at 1-800-473-3549 or DSN798-3764 as soon as possible.

1. Describe the light you saw

- What color(s) was the light(s)?
- How bright was it?
- How long was it on?
- Was it uniform in appearance?
- Did the intensity of the light change?
- Was it constant or did it pulse or flicker? If so, how fast did it pulse or flicker?
- How wide (perhaps using finger widths at arm's length) was the beam at origin?
- How wide on exposure was the light? Did the light fill your cockpit or compartment?
- Was the light emanating directly from a source or was it reflected off a surface?
- Were there any other unusual light sources?
- Have you seen this light(s) before?

2. Date, location, and circumstances

a. Date and time (local & Zulu using a 24-hour clock) that the exposure occurred.

local: DDMMYYYY hh:mm

Zulu: DDMMYYYY hh:mm

b. Location of exposure (if nonclassified). Describe location preferably using degree decimal (DD), degrees-minutes-seconds (DMS), Universal Transverse Mercator (UTM), or Military Grid Reference System (MGRS).

c. How far and in what direction was the light source? Was it airborne or surface based?

d. What was between the light source and your eyes?

e. What were the atmospheric conditions: clear, overcast, rainy, foggy, hazy, and sunny?

f. Was any equipment such as windscreens, visors, NVGs, goggles or sensors affected by the light?

g. What evasive maneuvers did you attempt and did the beam follow you as you tried to move away?

3. Effects

a. How long did you look into the light beam?

b. Did you look straight into the light beam or off to the side?

c. What tasks were you doing when the exposure occurred? Did the light(s) hamper you from doing those tasks?

d. Were both eyes exposed? If not, describe the difference between the light exposure (for example, one eye was shielded or closed, or on the side away from the light beam).

e. Describe any difference in the effect on either eye.

f. Was the light so bright that you had to blink or squint, close your eyes, or look away?

g. Was the light painful? Describe the pain. For how long did the pain persist after the light exposure?

h. Was vision affected while the light was on? How much of your visual field was affected? What types of things could you see or not see? Did you notice the color of instruments or targets change? Did the changes to your vision remain constant or vary during the exposure? If the light source was mounted on a platform (e.g., aircraft, ground vehicle, or building), how much of the platform was obscured?

i. Did your vision remain affected after the light was extinguished? If so, for how long and how did you estimate the time? What types of things could you see or not see? Did you notice afterimages (“spots before your eyes”)? If so, describe them.

j. Were there any lingering (i.e. hours or days) visual effects? If so, were the effects continuous or intermittent? Did you have problems reading or seeing in low-light conditions? How long until you were able to see normally again?

k. Did you notice any reddening, warming, or burns to your skin?

l. Describe the condition of your vision before the incident. Do you wear glasses?

m. Are you taking any medications?

APPENDIX C: AMSLER GRID/FOVEAL GRID TESTING INSTRUCTIONS

An accurate and validated grid for testing with instructions (Aidman Vision Screener) is available through the U.S. Army Public Health Center, Health Information Products e-Catalog: https://usaphcapps.amedd.army.mil/HIOShoppingCart/viewItem.aspx?id=452.

If pre-printed copies are not available, the vision screener may be printed full size for expedient screening.

GENERAL INSTRUCTIONS:

1. Have Service Member wear current glasses or correction if normally used for near vision.
2. Evaluate each eye separately under good lighting conditions, begin with the right eye (cover left eye).
3. Hold the sheet 40 cm/16 inches from the eye.
4. Ask Service Member to:
    a. Describe the center of the grid (may be unable to see center)
    b. Determine if all four corners of the diagram are visible.
    c. Identify any dark, hazy, or missing areas on the grid while SM focuses on central dot. Have SM draw these areas on the chart.
    d. Identify any distorted or wavy lines on the grid while focusing on the central dot. Have SM draw these areas on the chart.
5. Repeat test for left eye (cover right eye).
6. Document Amsler grid testing in medical record.

Ocular Coherence Tomography (OCT	Flight Surgeons complete additional evaluation and testing required for aviation personnel based on training and Service-specific guidelines.	
Automated Visual Field (VF)	Accomplished at the earliest role of care with available technology. Repeat testing should be done to monitor for progression based on the clinical situation.	

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

INTRODUCTION

Evaluation and treatment of ocular injuries and vision threatening conditions in a prolonged field care (PFC) situation can be extremely challenging. These events can lead to irreversible loss of vision with lasting effects on military service and overall quality of life. The goal of this clinical practice guideline (CPG) is to provide medical professionals with essential information on the recognition and treatment of ocular conditions when evacuation to an eye specialist is delayed. The guidelines are based on standard ophthalmic practice adapted to address the austere or remote environment, when the "Shield and Ship" guidelines are interrupted by delayed evacuation.

As with all medical concerns, recognition of the problem is the first step. This is a particular challenge for ocular conditions. Comprehensive ocular evaluation is not usually possible in austere locations and training in rapid recognition of ocular conditions may be limited. The ocular conditions covered in this guideline are the most common traumatic injuries and vision-threatening conditions that require rapid identification and treatment to prevent loss of vision. A more comprehensive review can be found in the Joint Trauma System CPG[1] or Wilderness Medicine textbook.[2]

Telemedicine: Management of eye injuries is complex. Detailed physical examination information can only be communicated via pictures or video. Establish telemedicine consultation as soon as possible.

GOALS OF CARE

1. MAINTAIN HIGH SUSPICION FOR OCULAR INJURIES

The mechanism of injury will often suggest an ocular injury. Direct trauma with ocular laceration may be fairly obvious, but blunt trauma leading to an occult rupture on the posterior aspect of the globe or injury to the retina can be easily overlooked in a multitrauma patient. Small metallic fragments can penetrate the eye and leave it appearing deceptively intact. An awake and alert patient can report change in vision or eye pain; an unconscious patient cannot. Thermal burns to the face frequently cause eyelid burns and contraction, which increase the risk for exposure keratopathy. Critical details in the evaluation of ocular trauma include mechanism of injury and presence of properly worn ballistic eyewear at the time of injury.

2. ASSESS AND DOCUMENT VISUAL FUNCTION

Visual acuity is the vital sign of the eye. Whenever possible, visual acuity should be assessed and documented. Visual function immediately after trauma is an important prognostic indicator for visual outcome. Visual acuity can be effectively estimated with several field-expedient methods, starting with ability to read any printed letters such as labels on medical supplies. If the patient is unable to read letters, assess their ability to count fingers. If they cannot count fingers, evaluate for the ability to detect hand motions. If they cannot detect hand motion, evaluate light perception using a bright light. Document visual acuity along with other vital signs.

Assessing for a relative afferent pupillary defect (RAPD, also called the swinging flashlight test or Marcus Gunn Pupil; Appendix A) gives an indication of retina and optic nerve function. Shine a light in either eye; normally, both pupils should constrict equally. This reaction to light is equal unless there is damage to the optic nerve or the retina, in which case the pupil of the injured eye will dilate when the light is shone in the injured eye. Evaluating for an RAPD is essential in conditions such as retrobulbar hemorrhage (orbital compartment syndrome) or suspected retinal detachment. Notation of an RAPD is also an important prognostic factor for ophthalmic providers at later level of care.

3. EXAMINE FOR CRITICAL PHYSICAL FINDINGS

An obvious globe laceration or rupture with prolapsed intraocular contents can be a striking picture but may not be present in every severe eye injury. At times, the only findings of a significant eye injury may be penetrating periocular trauma or lid lacerations, a peaked or teardrop pupil, or abnormal anterior chamber depth.

Estimation of intraocular pressure (IOP) is essential in injuries such as retrobulbar hemorrhage, but is contraindicated in injuries with obvious or suspected open globe injury (OGI). If no OGI is suspected, IOP can be estimated using a two finger method. Using the index finger of each hand, gently apply alternating pressure on the globe through closed lids. There should be mild indentation of the eye with normal IOP (normal range, 10–21mmHg). With increased IOP, the globe will be much firmer when compared to the opposite eye, or the examiner's own eye. The orbit around the eye may also feel tense in a retrobulbar hemorrhage.

A more detailed examination of the eye can be facilitated by the use of a direct ophthalmoscope for magnification. The examiner can use the plus lens dial (green or black numbers) to provide additional magnification. Details are found in Appendix B Use of the Direct Ophthalmoscope. Although deployed locations may have specific guidance against contact lens use, this may still be encountered. If a contact lens is clearly visible and accessible, it can be gently removed with forceps. Fluorescein will stain a contact lens, allowing for easy visualization.

4. MAINTAIN PATIENT COMFORT. PREVENT FURTHER DAMAGE.

Pain control is an important component of care in ocular injuries. Standard Tactical Combat Casualty Care (TCCC) pain control guidance applies to ocular injuries, including analgesic doses of ketamine if needed in systemic polytrauma. Additional guidance for pain control in PFC may be found in the CPG *Analgesia and Sedation Management during Prolonged Field Care*.[3]

Pain is not always present with serious eye injuries, and lack of pain should not be interpreted as lack of injury. Ocular injuries can cause a great deal of anxiety for patients, and this may affect care. A benzodiazepine may be added to the treatment plan for anxiety control and facilitation of care (diazepam 10 mg by mouth [PO] every 6 hours as needed).

A traumatized eye is highly susceptible to further damage; antiemetic medications are essential to prevent retching and increased pressure that can have significant effects on visual outcome.

Patching both eyes to decrease sympathetic eye movements has not been shown to improve visual outcome. Occluding both eyes will render the patient unable to move independently, may increase anxiety, and may put the patient and provider at increased risk in any PFC environment. The use of standard eye protection during patient transport can reduce the risk of further ocular injury or injury to the fellow eye. Eye protection can be used over a rigid shield to provide increased protection.

5. ESTABLISH CONTACT WITH EYE CARE SPECIALIST. PRIORITIZE EVACUATION.

Determining the full extent of ophthalmic injuries and the resultant threat of permanent loss of vision is challenging without full ophthalmic training and equipment. All potential vision-threatening injuries should be evacuated with a goal of care by an eye surgeon within 24 hours. In some cases, with prompt teleconsultation or video consultation, it may be safe to delay evacuation to reduce the effect on the operational situation while providing necessary ophthalmic care. Evacuation within 24 hours is not possible in all situations; therefore, the goal of teleconsultation and forward care is to reduce morbidity and achieve the best possible outcome. In some operational environments, optometrists may be available to provide additional care or consultation closer to the point of injury.

Ocular examinations have many specialized components that a specialist may request. An example template with explanation can be found in Appendix C Basic Ocular Examination.

SPECIFIC CONDITIONS

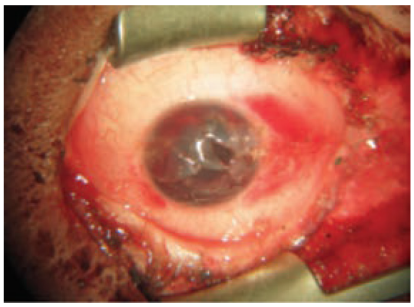
1. OPEN GLOBE INJURY

OGIs can result from penetrating/perforating trauma or from rupture of the globe due to massive compressive forces (Figures 1–5). Prompt surgical exploration and repair are crucial to restore or salvage vision and to prevent a devastating outcome. Safe and effective closure of an OGI is not yet feasible in a prehospital setting.

Figure 1. Open globe injury with corneal laceration, abnormal pupil shape, and blood in anterior chamber.

Figure 2. Central corneal laceration and lid laceration (due to large intraocular foreign body).

Figure 3. Multiple, deep corneal lacerations, found to be closed globe injury on surgical exploration.



Photographs by COL Mark Reynolds.

Goals

Prevent further damage to the eye, prevent infection in the eye (endophthalmitis), and evacuate to an eye surgeon as soon as possible.

Minimum

- Maintain high suspicion for OGI; treat any suspected open globe as an open globe until surgical exploration is available.
- Obtain and record visual acuity from the injured and noninjured eye.
- Apply a rigid eye shield without any type of gauze or bandaging under the shield to prevent further damage, per TCCC guidelines.4
- Initiate endophthalmitis prophylaxis with moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily; if intravenous (IV) administration is necessary, ertapenem 1g IV or intraosseously (IO) daily.5 Initiate pain control as needed.
- Initiate antiemetic (ondansetron 4mg oral dissolving tablet [ODT] IV/IO or intramuscularly [IM] every 8 hours as needed).
- Raise head 30°–45°.
- Activate evacuation with the goal of surgery within 24 hours.
- Initiate teleconsultation with photographs.

Better

- Minimize patient movements; maintain supine position with head at 30°–45°.
- Maintain endophthalmitis prophylaxis with an additional dose of moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily; if IV administration is necessary, ertapenem 1g IV/IO daily and the addition of clindamycin 300mg PO or IV every 8 hours if available; this is to cover Bacillus cereus, a particular concern in contaminated OGI.6
- Maintain antiemetic and pain control.

Best

- Perform a detailed ocular evaluation to include visual acuity and RAPD, and note any suspicious findings.
- Evaluation should be repeated with any reported change in vision or pain level by the patient. If symptoms are stable, perform ocular evaluation every 4 hours and before transfer.

Initiate real-time video telemedicine consultation.

- Coordinate surgical care within 8 hours of injury.
- No altitude restrictions are required for OGIs.

NOTES:

- Ultrasound is contraindicated for suspected OGI because it places pressure on the eye.
- Rigid eye shields are available in several different designs. Fit should be checked to ensure protection without any pressure on the eye. Standard eye protection may also be used to shield the injured eye.

Figure 4. Open globe with posterior rupture and collapsed anterior chamber.

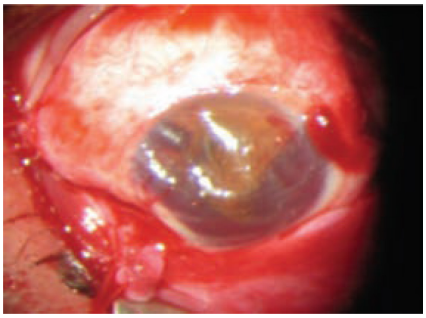


Figure 5. Post-traumatic endophthalmitis with inflamed conjunctiva, and inflammatory cells layered in anterior chamber.

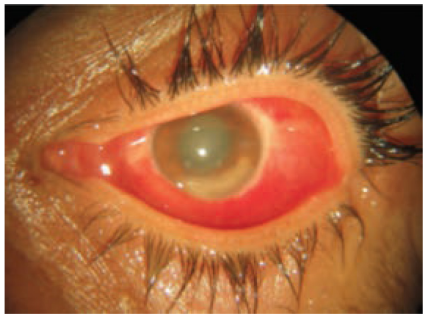


Photographs by COL Mark Reynolds.

2. RETROBULBAR HEMORRHAGE / ORBITAL COMPARTMENT SYNDROME

Retrobulbar hemorrhage (RBH) is the most common cause of orbital compartment syndrome (OCS). It is a result of bleeding into the confined orbital space behind the eye, usually associated with blunt trauma (Figures 6 and 7). It is a vision-threatening condition causing increased pressure in the eye, leading to irreversible vision loss. Vision loss typically will occur after approximately 90 minutes of increased pressure.

Figure 6. Retrobulbar hemorrhage (pupil dilated for examination).

Figure 7. Retrobulbar hemorrhage, evaluation for proptosis.

Photographs by COL Mark Reynolds.

Other causes of OCS include orbital congestion secondary to burn resuscitation and significant orbital emphysema after orbital fracture (pneumo-orbita). OCS from any cause may have a delayed onset. Patients with trauma to the orbit must be closely monitored for development of OCS.

Goal

Lower the orbital compartment pressure as soon as possible to prevent tissue damage.

Minimum

- Prompt recognition of injury and identification of the need for intervention
- History of trauma with any of the following findings:
  - Proptosis: bulging of the affected eye compared with the other eye; proptosis in RBH is often tense and painful
  - Increased orbital pressure around the eye or IOP by palpation (increased firmness and resistance compared with opposite eye)
  - Decrease in or loss of visual acuity
  - Presence of an RAPD (Appendix A)
- Raise head 30°–45°.
- Initiate pain control as needed.
- Initiate antiemetic (ondansetron 4mg ODT/IV/IO/IM every 8 hours as needed).
- Perform lateral canthotomy/cantholysis (LCC) as soon as possible, within 90 minutes of injury if evacuation to a surgical capability is anticipated to take more than 60 minutes.
- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Initiate teleconsultation with photographs.

Better

- Minimize patient movements; maintain supine position with head at 30°–45°.
- Ice packs and avoidance of compressive dressings[7]
- Monitor for return of elevated orbital pressure.

Best

- Initiate a detailed ocular evaluation and continue monitoring IOP, vision, and RAPD.
- Continue to check for recurrence of elevated IOP even after LCC. If the vision deteriorates and the eye again becomes firm after LCC, this may signify rebleeding in the orbit. Evacuation of orbital hemorrhage is not feasible in a PFC environment and rebleeding will require medical treatment.[8]
  - Acetazolamide: 500mg PO initial dose, followed by 250mg PO 4 times per day (Note: contraindicated in patients with sickle cell trait)
  - If acetazolamide is not available or if the patient cannot take PO, either 3% hypertonic saline 250mL IV or mannitol: 1g/kg IV over 30–60 minutes can be used to decrease IOP.[9]
  - Corticosteroid: 1g methylprednisolone IV once [10]
  - Initiate real-time video telemedicine consultation.
  - No altitude restrictions are required for evacuation.

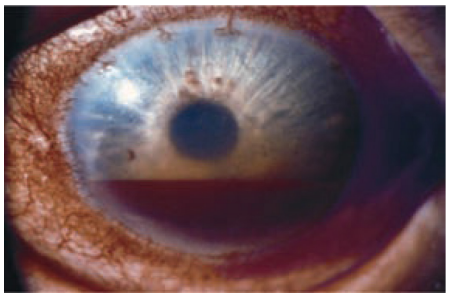
NOTES:

- LCC is a vision-saving procedure with minimal risk of causing additional ocular injury. When in doubt, perform the LCC immediately.
- In thermal burns, consider early LCC (before full OCS develops). Fluid resuscitation requirements will take precedence over the use of medical treatments to reduce IOP.

3. BLUNT / CLOSED GLOBE INJURY

This category includes anterior segment injuries such as hyphema (bleeding into the anterior chamber) and posterior segment injuries such as vitreous hemorrhage and retinal detachment. Blunt trauma can result in severe loss of vision.

Figure 8. Layered hyphema in anterior chamber.



©2017 American Academy of Ophthalmology, reprinted with permission.

Hyphema can lead to increased IOP and corneal blood staining. This is graded on the amount of blood in the anterior chamber. The risk of IOP elevation increases with the grade of the hyphema (Figure 8).[11]

- Grade 0: no visible blood layering
- Grade 1: blood fills less than one-third of anterior chamber
- Grade 2: blood fills one-third to one-half of anterior chamber

- Grade 3: blood fills one-half to less than total anterior chamber
- Grade 4: blood fills entire anterior chamber

Goal

Identify significant ocular injuries; protect the eye from further injury.

Minimum

- Obtain and record visual acuity and critical injury details (e.g., mechanism of injury, presence of eye protection).
- Protect the injured globe and prevent further damage with a rigid shield.
- Raise the head 30°–45°; this allows any free-floating blood in the anterior chamber to settle away from the pupil and prevent pupillary block (which can lead to angle closure and elevated IOP).[11]
- Initiate pain control as needed; avoid nonsteroidal anti-inflammatory drugs, because of risk of worsening intraocular bleeding.
- Prevent further injury with antiemetics (ondansetron 4mg ODT/IV/IO/IM every 8 hours as needed).
- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Initiate teleconsultation with photographs.

Best

- Initiate a detailed ocular evaluation to direct treatment.
- Hyphema (anterior chamber injury)[11]
- Topical corticosteroid drop (prednisolone acetate 1%) 4 times per day
- Cycloplegic eye drop (cyclopentolate 1%), 1 drop every 8 hours
- Monitor for rebleeding when the clot in anterior chamber retracts, usually at 3–5 days after injury.
- This may result in vision change and increased size of hyphema.[12]
- If there is evidence of further bleeding or increasing IOP, initiate medications to decrease IOP:
  - Timolol 0.5%, 1 drop twice a day in affected eye
  - Acetazolamide 500mg PO initial dose, followed by 250mg PO 4 times per day (Note: contraindicated in patients with sickle cell trait) or 3% hypertonic saline 250mL IV or mannitol: 1g/kg IV over 30–60 minutes.

NOTE: Tranexamic acid for prevention of rebleeding in hyphema has not shown any benefit [13] but may be used in multitrauma patients if otherwise indicated.

Posterior chamber injury: Injuries to the retina and optic nerve as a result of blunt injury will result in vision loss. Findings may include decreased visual acuity, vision loss, loss of red reflex through the pupil, positive RAPD, or evidence of vitreous hemorrhage or retinal detachment on ultrasound evaluation.

- Initiate supplemental oxygen as available if suspicious for retinal detachment (e.g., cut in visual field, decreased vision, positive RAPD); this may improve visual outcome.[14]
- If no evidence of OGI, perform careful ultrasound to evaluate vitreous and retina, if available/trained. Transmit ultrasound images with telemedicine consultation to an eye specialist.

Initiate real-time video telemedicine consultation.

- No altitude restrictions are required for blunt/closed globe injury.

4. EYELID LACERATION

Lid lacerations can result from either sharp or blunt trauma (Figures 9–11). As with other injuries, the primary concern with lid injuries is the possibility of underlying globe injury. Lid lacerations have a low incidence of infection (unless the causative factor is an animal or human bite). Any avulsed tissue should be preserved in saline and chilled, whenever possible, and sent with the patient—not discarded or debrided. Meticulous closure of eyelid structures with proper magnification is usually required to maintain lid function. If fat is visible in an eyelid laceration, this indicates violation of the orbital septum, a key anatomic barrier to infection. If prolapsed orbital fat is identified, appropriate antibiotic coverage is needed as well as expedited evacuation for surgical exploration and repair. Do not attempt to excise or suture exposed orbital tissue; this can lead to uncontrolled bleeding in the orbit.

Figure 9. Eyelid margin laceration

Figure 10. Complex lid laceration with medial canthus avulsion

Figure 11. Eyelid laceration with tissue loss due to camel bite.

Photographs by LTC Marcus Colyer (9) and COL Mark Reynolds (10, 11).

Goals

Prevent infection; protect the eye from further injury.

Minimum

- Maintain high suspicion for OGI; treat any suspected open globe as such until surgical capability is available.
- Obtain and document visual acuity from the injured and noninjured eyes.
- If there is any concern for OGI, protect the injured globe and prevent further damage with a rigid eye shield. Polyethylene film (food grade) may be used to cover the eyelid wound under the rigid shield to prevent drying of the injured tissue.
- Initiate pain control as needed.
- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Initiate teleconsultation with photographs.

Better

For foreign body penetration, animal bite, or laceration with visible orbital fat, start antibiotics: moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily or amoxicillin/clavulanic acid 875mg/125mg PO every 12 hours or ertapenem 1g IV/IO daily.

Best

- Initiate a detailed ocular evaluation to include visual acuity, RAPD, and note any suspicious findings.
- Irrigate wound very gently with clean water (or sterile saline, if available).[15]
- Do not debride any tissue.
- Temporary closure with steristrips
- Tetanus prophylaxis
- Consider the need for rabies vaccination.[15]

Initiate real-time video telemedicine consultation.

- No altitude restrictions are required for evacuation.

5. ORBITAL FRACTURE

Fracture of the orbital bones occurs when an object that is larger than the width of the orbit (e.g., fist or softball) strikes the orbit. The acute expansion of orbital contents and mechanical buckling forces can result in fractures of the medial wall or orbital floor. This can cause herniation of orbital contents into the surrounding sinuses and entrapment of the extraocular muscles in the fracture site. Physical examination findings consistent with orbital fracture include a palpable and painful step-off along the orbital rim, enophthalmos (globe is further back in the orbit compared with the other eye), restricted eye movement, and numbness below the eye (caused by damage to the infraorbital nerve).[16] Trismus and malocclusion may indicate a larger zygomaticomaxillary complex fracture. Orbital fractures are not ophthalmic emergencies but may require surgical treatment to prevent the complication of double vision from ocular misalignment.

Goals

Evaluate for concurrent open or closed globe injury and prevent long-term complications.

Minimum

- Maintain a high suspicion for associated OGI; treat as a suspected open globe until eye surgical evaluation is available.
- Obtain and record visual acuity from the injured and noninjured eyes.
- Instruct the patient not to blow nose. This may force air into the orbit through fracture site, leading to OCS from pneumo-obita, which would require LCC.
- Initiate pain control as needed.
- Raise head 30°–45°.

Initiate teleconsultation with photographs.

- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Better

- Initiate antibiotics if an orbital fracture suspected; this is to prevent sinus pathogens from spreading to the orbital tissues: moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily or amoxicillin/clavulanic acid 875mg/125mg PO every 12 hours or ertapenem 1g IV/IO daily.
- Nasal decongestants such as oxymetazoline (e.g., Afrin; Bayer, http://www.bayer.us/) nasal spray twice a day for 3 days (limit use to 3 days to prevent rebound effect). Oral decongestants, such as pseudoephedrine 30mg every 6 hours, can be used if nasal spray is not available.
- Prevent further injury with antiemetics (ondansetron 4mg ODT/IV/IO/IM every 8 hours as needed).

Best

- Initiate a detailed ocular evaluation to include visual acuity, RAPD, and note any suspicious findings.
- Ice packs for 20 minutes every 1–2 hours for the first 48 hours to reduce swelling.
- Monitor for delayed development of OCS and perform LCC as needed.

Initiate real-time video telemedicine consultation.

NOTES:

- No altitude restrictions are required with orbital fractures, but patient should be monitored for increasing pain and/or decreasing vision from pneumo-orbita OCS requiring LCC.
- An important consideration in orbital floor fractures is the inferior rectus muscle becoming entrapped in the fracture (so-called trapdoor fracture). The resultant traction on the rectus muscle can trigger the oculocardiac reflex and result in intractable nausea and vomiting, symptomatic bradycardia, and possibly heart block. Although this is more common in pediatric patients (termed "white-eye" blow-out fractures), it is not exclusive to the pediatric population and has been reported in young healthy adults. Urgent surgical repair (within 72 hours) is recommended for an entrapped fracture with these symptoms.

6. CHEMICAL INJURIES

Acid (e.g., sulfuric, hydrochloric) and alkali (e.g., bleach, lime, ammonia) burns can cause significant injuries leading to permanent loss of vision and are considered ophthalmic emergencies. Alkali burns are more common and have more potential for damage than acid burns.16 Ongoing ocular care beyond the initial thorough irrigation will be required if evacuation is delayed. Chemical injuries are graded on a scale of I to IV.[17] The modified Hughes classification (Table 1) can be used to grade the degree of limbal ischemia that correlates with prognosis. Regardless of the chemical causing the injury, immediate irrigation is the essential first step. Additional treatment will be based on grade of injury. Injuries are graded on the basis of the following examination findings (Figures 12–14):

Table 1. Modified Hughes Classification

Grade	Cornea Epithelium	Corneal Clarity	Limbal Ischemia
I	Less than one-third loss	Iris details clearly visible	No ischemia
II	More than one-third epithelial loss	Iris details blurred but visible	Less than 25% ischemia
III	Complete epithelial loss	Pupil can be seen	25%–50% ischemia
IV	Complete epithelial loss	Opaque cornea	More than 50%

- Corneal epithelial damage: How much epithelium has been lost?
- Clarity of cornea: Can the normal structures (iris, pupil) be seen through the cornea?
- Limbal ischemia: Does the conjunctiva at the edge of the cornea appear normal or are there areas that are blanched white?

  Grade I injuries may have corneal epithelial damage but a clear cornea, no corneal opacity, and no limbal ischemia.

  These injuries generally carry a good prognosis for recovery. Irrigation and topical care are frequently the only required interventions.

  Grade II through IV injuries will have corneal haze or opacity and limbal ischemia.

  These injuries will have a guarded prognosis and will require more intensive treatment. Grading is determined by the most severe finding. For example, an eye with a clear cornea but showing limbal ischemia would be classified as grade II or higher.

Goals

Initiate eye irrigation as quickly as possible to reduce damage to the eye, treat the injury to prevent or reduce scarring and visual loss.

Minimum

- Immediate thorough irrigation to remove the chemical agent is the essential first step (IV fluid, sterile water, or clean water).
- Continue irrigation, using at least 2L of fluid.
- Use tetracaine eye drops as needed to facilitate irrigation (unpreserved lidocaine 2% can be substituted as eye drops if tetracaine is not available).
- Irrigation may not flush all chemical agents from the eye; examine for particulate matter and remove using a cotton tip applicator (CTA).
- Initiate pain control as needed. DO NOT use topical anesthetics for pain control; they significantly impair corneal healing.
- Initiate teleconsultation with photographs (include full facial views).

Figure 12. Grade II chemical injury with ischemia and epithelial defect.

Figure 13. Grade III chemical injury.

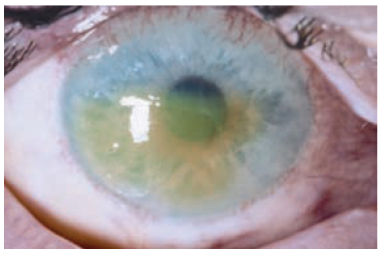


Figure 14. Grade IV chemical Injury.

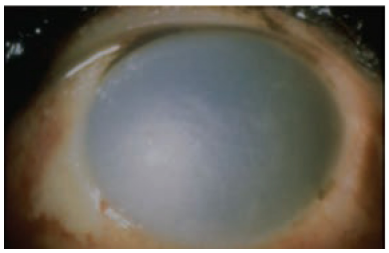


Photographs by The University of Iowa and EyeRounds.org (12) and ©2017 American Academy of Ophthalmology, reprinted with permission. (13, 14).

Better

- Evaluate ocular pH using a urine test strip and CTA.
- Do not place the test strip directly on the eye. Roll a
- CTA across the conjunctival surface and then onto the test strip. If pH ≠ 7, continue irrigation and recheck until pH = 7.

Best:

- Initiate real-time video telemedicine consultation; treatment duration for more significant chemical burns will vary depending on the injury and are best determined by an eye-care specialist
- Further treatments and need for evacuation will be directed by the grade of injury. Evaluation will require fluorescein strips to evaluate the corneal epithelium and a light source, preferably with a red-free option (i.e. green lens), for evaluation of limbal ischemia.

Grade I:

- Topical antibiotic ointment (e.g., erythromycin ophthalmic ointment) 3 times per day Cycloplegic eye drop (cyclopentolate 1%), 1 drop every 8 hours, if available, for photophobia
- Preservative-free artificial tears 3 times per day, alternating between ointment treatments

Grades II–IV:

- Moxifloxacin 0.5% eye drops, 1 drop every 8 hours
- Topical corticosteroid (e.g., tobramycin/dexamethasone or prednisolone acetate 1%) 1 drop every hour while awake
- Cycloplegic drop (cyclopentolate 1%), 1 drop every 8 hours, if available
- Doxycycline 100mg PO every 12 hours; this has anti-inflammatory and anticollagenase benefits for the ocular surface.
- The following have been shown to improve corneal healing with severe chemical burns; add to the treatment if available:
  - Vitamin C 2g 4 times per day.[17]
  - Supplemental oxygen (administer 100% for 1 hour twice daily).[19] No data are available for the effectiveness of lower doses of oxygen.
- Reassess frequently until evacuation.
- No altitude restrictions for flight

7. PRESEPTAL AND ORBITAL CELLULITIS

Infection anterior to the orbital septum (usually involving the eyelid) is termed preseptal cellulitis. Preseptal cellulitis will present with tenderness, swelling, and erythema of the eyelids, with no orbital findings (e.g., no sign of proptosis, eye movement restriction, or change in vision). Preseptal cellulitis can generally be managed with oral antibiotics, but the possibility of methicillin resistant Staphylococcus aureus (MRSA) must be considered.

Infection in the orbit (posterior to the orbital septum) can occur as a result of adjacent sinusitis, skin infection, puncture wounds, or orbital foreign bodies. Multiple organisms, including staphylococcal, streptococcal, and gram-negative bacteria, are usually responsible. Orbital cellulitis has the potential to progress rapidly and may lead to irreversible loss of vision or intracranial extension. Orbital cellulitis presents with pain, proptosis, conjunctival injection, decreased vision, and loss of ocular mobility (which may cause double vision).

Goal

Recognize infection early and start oral antibiotics for preseptal cellulitis and IV antibiotics for orbital cellulitis. Evacuate to an eye surgeon as rapidly as possible if orbital cellulitis is suspected.

Preseptal cellulitis (Figure 15)

- Minimum
- Moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily.
- Does not cover MRSA; follow closely for worsening condition.
- Initiate pain control as needed.
- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.
- Initiate teleconsultation with photographs.

Best

Trimethoprim sulfamethoxazole DS 1 tablet PO every 8 hours combined with amoxicillin/clavulanic acid 875mg every 12 hours.

Orbital cellulitis (Figure 16)

Minimum

- Prompt recognition of the condition and the need for rapid intervention
- Initiate pain control as needed.
- Initiate IV access with broad-spectrum IV antibiotics: ertapenem 1g IV/IO daily or levofloxacin 500mg IV once a day.
- Initiate pain control as needed.
- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Initiate teleconsultation with photographs (include full facial views).

Figure 15. Preseptal cellulitis

Reprinted with permission of the University of Iowa and EyeRounds.org.

Figure 16. Orbital cellulitis

Reprinted with permission of the American Academy of Ophthalmology.

Better

Nasal decongestants such as oxymetazoline (e.g., Afrin) nasal spray twice a day for 3 days (limit use to 3 days to prevent rebound effect); this will aid in draining of contributing sinusitis. Oral decongestants, such as pseudoephedrine 30mg every 6 hours, can be used if nasal spray is not available.

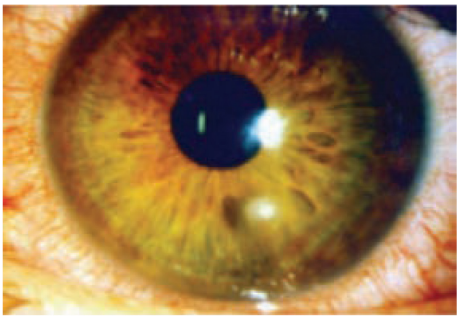
Best

- Initiate a detailed ocular examination.
- Monitor vision every 4 hours until evacuation (may take 24–36 hours to show improvement).
- Initiate real-time video telemedicine consultation.
- No altitude restrictions for flight

8. INFECTIOUS KERATITIS (CORNEAL ULCER)

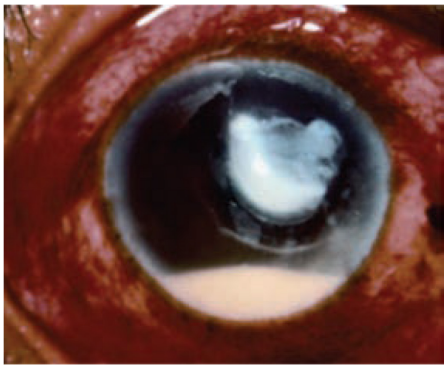
Infections in the cornea can lead to corneal scarring and permanent effects on vision (Figures 17 and 18). The most common risk factor for corneal ulcer is contact lens use.

Figure 17. Early corneal ulcer



Photograph courtesy of John D. Sheppard, MD, and Clelia Sheppard.)

Figure 18. Advanced corneal ulcer



Reprinted with permission of the American Academy of Ophthalmology.

Goal

Early recognition and treatment to prevent long-term scarring of the cornea.

Minimum

- Moxifloxacin eye drops 1 drop every 15 minutes for the first 2 hours after diagnosis, then 1 drop every hour while awake
- Initiate pain control as needed. DO NOT use topical anesthetics for pain control; they significantly impair corneal healing.
- Initiate teleconsultation with photographs.
- Activate evacuation (goal is ophthalmic care within 24 hours if lesion is large, central, or affects vision).

Better

- Obtain a culture before beginning treatment for sight-threatening or severe keratitis with suspected infection, such as large central corneal infiltrate that extends to the middle to deep stroma.[20]

- Provide intense loading dose of moxifloxacin 0.5% eye drops 1 drop every 5–15 minutes for the first 30–60 minutes (patient can self-administer loading dose if reliable) after culture obtained.
- Treatment dose: 1 drop every 30–60 minutes around the clock until epithelial defect is closed.[20]
- Cycloplegic eye drop (cyclopentolate 1%), 1 drop every 8 hours for photophobia.

Best

- Real-time video telemedicine consultation
- Collagen corneal shield (national stock no. [NSN] 6515-01-482-9391) soaked in moxifloxacin drops for transport (generally 5–10 drops) and placed over the corneal infiltrate. This enables release of the medication to the ocular surface during transport, rather than administering repeated dosing.[21]
- No altitude restrictions for flight

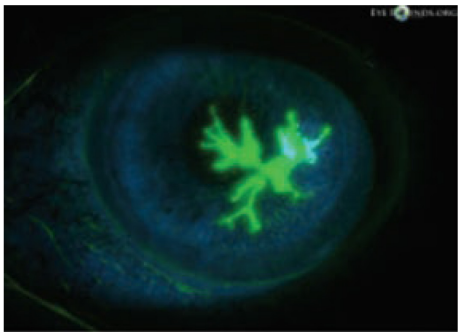
NOTE: Topical steroid drops may be useful to reduce inflammation after the infection is controlled with topical antibiotics. Initiation of topical steroid drops should only be done under the direction of an eye care specialist after teleconsultation.

Herpes simplex virus (HSV) keratitis is an additional form of keratitis that usually occurs in patients with a history of previous episodes. HSV keratitis may demonstrate a specific dendritic staining pattern with fluorescein (Figure 19). After recognition, treatment can be initiated with oral acyclovir (400mg PO 5 times per day).

9. ANGLE -CLOSURE GLAUCOMA

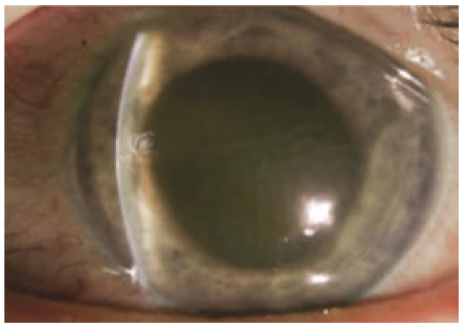
Blockage of the normal flow of aqueous fluid in the anterior chamber of the eye will lead to increased IOP. If left untreated, blood flow to the posterior segment of the eye will be affected, leading to irreversible vision loss. The aqueous drain system can become blocked owing to anatomic variations, changes in lens size, inflammation, and trauma (Figure 20).

Figure 19. Dendrite staining with fluorescein in herpes simplex keratitis.



Reprinted with permission of the University of Iowa and EyeRounds.org.

Figure 20. Angle-closure glaucoma



Reprinted with permission of the American Academy of Ophthalmology.

Goals

- Prompt diagnosis and identification, lowering of IOP.
- Minimum
- Diagnosis
- Pain (often described as a deep pain, similar to tooth pain)
- Decrease in or loss of visual acuity

- Photophobia
- Dull or cloudy appearance of the cornea due to corneal edema
- Fixed, mid-dilated pupil (usually occurs after IOP reaches 30–40mmHg)
- Increased IOP by palpation
- Acetazolamide 500mg PO initial dose, then 250mg PO every 4 hours to decrease IOP. (***Note***: contraindicated in patients with sickle cell trait.)

Initiate teleconsultation with photographs.

- Activate evacuation with goal of evaluation by an eye surgeon within 24 hours.

Better

- Oral acetazolamide plus topical IOP-lowering eye drops (timolol 0.5%, 1 drop twice a day in the affected eye).
- Administer antiemetics as required by patient symptoms (ondansetron 4mg ODT/IV/IO/IM every 8 hours as needed).

Best

- Topical corticosteroids (prednisolone acetate 1%) 1 drop every hour after consultation with ophthalmology or optometry.
- 3% hypertonic saline 250mL IV or mannitol 1g/kg over 30–60 minutes can be used to decease IOP if the aforementioned interventions are not effective.[9]

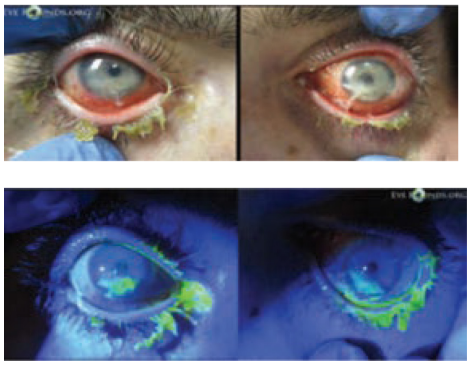
10. EYE CARE IN THE MULTITRAUMA / THERMAL BURN PATIENT

Patients with multisystem trauma who are intubated and sedated are at risk of developing corneal complications due to metabolic derangements and impaired ocular protective mechanisms.[22] The presence of thermal facial burns puts the patient at high risk for exposure keratopathy. Loss of the normal blink reflex, impaired tear production, abnormal tear film dynamics, and incomplete eyelid closure, combined with the inability to relay ocular complaints all contribute to the development of exposure keratopathy and increase the risk for infectious keratitis.[23] If there is no concern for OGI, ultrasound examination may be performed if personnel are equipped and trained. Patients with head and facial burns with eyelid involvement are especially prone to entropion (with burned eyelash stubs abrading the cornea) as well as exposure keratopathy from scar-related lid retraction and proptosis from orbital congestion (Figures 21 and 22).

Figure 21. Extensive facial burns with lid contraction and orbital congestion.

Photograph by COL Mark Reynalds

Figure 22. (A) Exposure keratopathy; (B) with fluorescein staining.



Reprinted with permission of the University of Iowa and EyeRounds.org

Goal

Prevent ocular exposure and corneal injury in high risk patients.

Minimum

Initiate ocular surface protection with sterile petrolatum or methylcellulose drops to keep the ocular surface from drying out. (Do not substitute a nonophthalmic lubricant).

For thermal facial burns, instill erythromycin ophthalmic ointment or sterile petrolatum every 2 to 4 hours.

Better

Gentle horizontal taping of lids with hypoallergenic tape in conjunction with ocular surface protection to protect the eyes.[24]

Evaluate the eyes and instill a surface protectant at least every 8 hours. Ensure the surface of the eye is not dry, there is no pressure on the eye, pupil reactivity has not changed, and the eyelids are completely closed to protect the eye.

Best

- Detailed ocular evaluation
- Cover eyes with polyethylene film to prevent drying.
- Food-grade film is safe for use around the eyes.
- Apply from the eyebrow to the maxilla to ensure proper coverage
- No altitude restrictions for flight

NOTE: Surgilube should never be instilled into the eye as a lubricant, because if can cause corneal toxicity.[18] When used for ultrasound examination, place a thin film (e.g., food-grade polyethylene or Tegaderm [3M, http://www.3m. com]) over the closed eyelid.

APPENDIX A: RELATIVE AFFERENT PUPILLARY DEFECT

Afferent Pupillary Defect

Injury to or disease of the optic nerve or retina will affect pupillary function. Under normal conditions, the pupils will react equally to light through the consensual pupillary reflex.

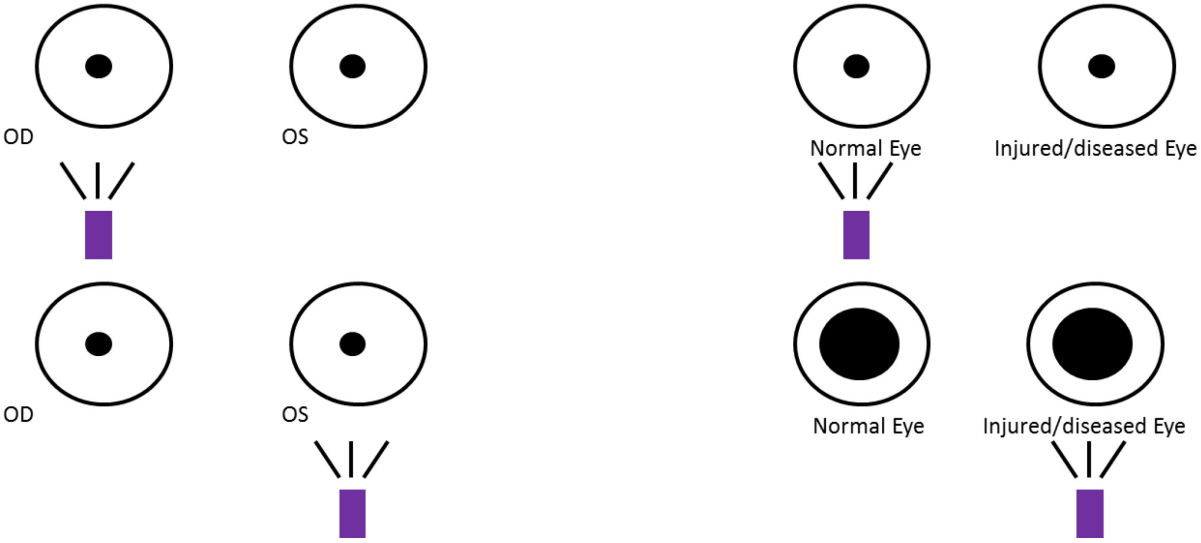
Equipment: Bright light source

Technique: Shine light into one eye and note pupillary response; swing light to opposite eye and observe response (expect equal constriction)

Abnormal Result: When swinging light source to injured/diseased eye, there will be a dilation of the pupils; this is due to the injured/diseased eye perceiving less light than the unaffected eye.

Significance: Allows for evaluation of visual pathways, even in unconscious patient

Common Causes: Retrobulbar hemorrhage, retinal detachment, traumatic optic neuropathy, advanced glaucoma



APPENDIX B: USE OF THE DIRECT OPTHALMOSCOPE

The direct ophthalmoscope is designed to use the patient's own optical system to magnify the optic disc and retina for diagnostic purposes, but it has multiple additional uses, such as obtaining a magnified view of the anterior segment, evaluating for visually significant cataract, and evaluating pupil responses in uncooperative or pediatric patients.

Equipment: Direct Ophthalmoscope

Techniques:

- To obtain a magnified view of the anterior segment of the eye. Viewing from 2-3 inches from the eye using the plus lenses (black or green numbers, ~5) will provide an enlarged view when evaluating for foreign bodies or corneal abrasions. Using the cobalt blue filter with fluorescein dye will enhance the view of corneal epithelial defects.
- To evaluate for cataracts, stand approximately 1 meter from the patient and evaluate the red reflex from the retina with no lens dialed in (no red or green numbers). Blockage of the red reflex will highlight any visually significant cataracts.
- To check for pupil reactivity in uncooperative patients or children, view the red reflex from 2-3 feet (again with no lenses dialed in); movie the light from one eye to the other and observe the change in the size of the red reflex.
- Assessment of retinal spontaneous venous pulsations may be possible in the setting of traumatic brain injury.[25]

APPENDIX C: BASIC OCULAR EXAMINATION

Basic Ocular Examination

Visual acuity → **Right** / **Left**

Measure with glasses in place (if available); record from chart or use card at 16 inches

- For vision less than 20/400, assess Finger Counting (FC) at 5 ft and 2 ft
- For vision less than finger counting, assess Hand Motion (HM) at 1 ft
- For vision less than Hand Motion, assess for Light Perception or No Light Perception
- Record with right eye (OD) on top, left eye (OS) on bottom

IOP:

Intraocular Pressure (T_{palp}): measure by palpation

- Normal range 10-21 mmHg
- Use 2 fingers to palpate eye through CLOSED lids
- Should feel similar to tennis ball (use other eye for comparison)
- Elevated intraocluar pressure (such as in Acute Angle Closure Glaucoma or Retrobulbar hemorrhage) will feel much firmer (like palpating over eyebrow)

Lids: Lesions, lacerations, edema, erythema, drooping (ptosis)

Conjunctiva/Sclera: Hyperemia(injection), discharge, injuries, masses, abnormal pigmentation

Cornea: Opacities, ulcerations, abrasions, foreign bodies, lacerations

Anterior Chamber: Approximate depth (shallow or deep), visible foreign bodies

Iris/Pupil: Reaction to light (direct and consensual) abnormal shape of pupil, iris abnormalities

Lens: Lens opacity (cataract)

Fundus: Abnormalities such as blood, scarring, papilledema, abnormal cupping of disc

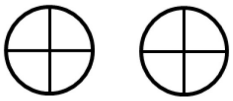
Assessment: Diagnosis, treatment and follow-up plan

EOM:

Extraocular Muscle Evaluation (EOM): assess eye movements in all fields of gaze

- Ask patient to follow your finger (without moving the head)
- Record any restrictions to movement

Vf_c:



Right **Left**

Visual Fields by Confrontation (Vf_c): evaluate limitations in the field of vision

- Sit/stand facing the patient , if testing the patient's right eye, close your left eye
- Present fingers to both sides of visual field simultaneously (generally 1 finger with one hand, 2 fingers with the other)
- Ask patient how many fingers they can see
- Record areas of visual field loss as seen from patient's perspective.

APPENDIX D: PACKING AND PLANNING CONSIDERATIONS

Level	Equipment	Medications
Minimum	Rigid Eye shield	Moxifloxacin 400 mg oral tablets or Levofloxacin 750 mg oral tablets
	Lateral canthotomy/cantholysis instrument set	Clindamycin 300 mg oral tablets
	Bright light source	Ketamine IV
	Visual acuity estimate reference	Odansetron oral dissolving tablets or IV
	Teleconsultation capability	Tetracaine eye drops or 2% lidocaine without epinephrine (unpreserved)
		Fluid for ocular irrigation
		Fluorescein ophthalmic stain
Better	Ice packs	IV ertapenem 1 gm
	Direct ophthalmoscope	Oxymetazoline HCL nasal spray
	Hypoallergenic tape	Erythromycin ophthalmic ointment
		Cyclopentolate hydrochloride 1% eye drops
		Moxifloxacin 0.5% ophthalmic drops
Best	Collgen eye shields (NSN 6515-01-482-9391)	Mannitol IV
	Steristrips	Acetazolamide 250mg oral tablets
	Polyethylene film (food grade)	Corticosteroids IV
	Oxygen source	Timolol 0.5% eye drops
	Urine test strips	Prednisolone acetate 1% eye drops
	Portable ultrasound with linear probe	Preservative-free artificial tears
		Tobramycin/dexamethasone combination eye drops (tobradex)
		Acyclovir 400 mg oral tablets
		Vitamin C
		Tetanus vaccine
		Human rabies immune globulin and rabies vaccine

APPENDIX E: OCULAR INJURIES & VISION THREATENING CONDITIONS SUMMARY TABLE

Eye Care Goals	
• Maintain high suspicion for ocular injuries. • Assess and document visual function. • Examine for critical physical findings. • Maintain patient comfort and prevent further injury (e.g., pain medication, anti-emetic, eye shield, elevate head 30º-45º). • Establish telemedicine contact with eye care specialist; provide photographs or real-time video. • For eyesight-threating conditions, prioritize evacuation with goal to arrive at an eye surgeon or eye specialist within 24 hours. • Provide optimal Role 1 care when evacuation goal cannot be met	
Open globe injury/suspected open globe	
Goal	Prevent further damage to the eye, prevent infection in the eye (endophthalmitis), and evacuate to an eye surgeon as soon as possible.
Minimum	Rigid shield, pain control, antiemetic, raise head 30º-45 º. Antibiotic prophylaxis: moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily or ertapenem 1g IV/IO daily.
Better	Add clindamycin 300 mg PO or IV/IO every 8 hours to endophthalmitis prophylaxis.
Best	Detailed ocular exam every 4 hours. Coordinate surgical care within 8 hours of injury.
Ultrasound is contraindicated for suspected OGI because it places pressure on the eye.	
Retrobulbar hemorrhage/orbital compartment syndrome (OCS)	
Goal	Lower the orbital compartment pressure as soon as possible to prevent tissue damage.
Minimum	Prompt recognition (i.e., bulging of eye, increased pressure by palpation, decreased vision, +RAPD). Lateral canthotomy/cantholysis (LCC) within 90 minutes of injury (if evacuation to surgical capability will take more than 60 minutes). Pain control, antiemetic, raise head 30º-45 º.
Better	Minimize patient movement, ice packs, monitor for return of increased intraorbital pressure (IOP).
Best	If rebleeding after initial response to lateral canthotomy/cantholysis, acetazolamide 500mg PO once then 250mg PO 4 times per day. If unable to take PO, 3% hypertonic saline 250ml IV or mannitol 1 g/kg IV over 30-60 minutes. Corticosteroid (e.g. 1g methylprednisolone IV once).
Relative afferent pupilary defect (RAPD), abnormal dilation of pupil when light is shined into injured eye. LCC is a vision-saving procedure with minimal risk of causing additional ocular injury. When in doubt, perform LCC.	
Closed globe injury (caused by blunt trauma)	
Goal	Identify significant ocular injuries; protect the eye from further injury.
Minimum	Document vision, pain control. Prevent further damage with rigid shield, anti-emetic, raise head 30º-45º.
Best	**Hyphema (anterior chamber injury):** Topical steroid eye drop (prednisolone acetate 1% 4 times per day) and cycloplegic drop (cyclopentolate 1% 1 drop every 8 hours). Monitor vision and IOP. Treat elevated IOP with timolol eye drops 0.5%, 1 drop twice a day or acetazolamide 500mg PO once then 250mg po 4 times per day. (Note: contraindicated in patients with sickle cell trait). If unable to take PO, 3% hypertonic saline 250ml IV or mannitol 1 g/kg IV over 30-60 minutes.
	Retina/optic nerve (posterior chamber injury): Supplemental oxygen. Perform careful ultrasound and transmit images with telemedicine consult.

Eyelid laceration	
Goal	Prevent infection, protect the eye from further injury.
Minimum	Maintain high suspicion for open globe injury (treat as such if suspected). Keep injured eyelid tissue moist by covering with polyethylene film (food grade).
Better	For foreign body penetration, animal bite, or laceration with visible orbital fat, start antibiotic: moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily or amoxicillin/clavulanic acid 875mg/125mg PO every twelve hours or ertapenam 1 gm IV/IO daily.
Best	Detailed ocular exam. Irrigate and perform temporary closure of wounds. Tetanus and rabies prophylaxis if indicated.
Orbital fracture	
Goal	Evaluate for concurrent open or closed globe injury and prevent long-term complications.
Minimum	Maintain high suspicion for open globe injury. No nose blowing. Pain control, antiemetic, raise head 30º-45º.
Better	Antibiotic moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily or amoxicillin/clavulanic acid 875mg/125mg PO every twelve hours or ertapenam 1 gm IV/IO daily. Initiate nasal decongestant (e.g., Afrin nasal spray twice a day for 3 days) or oral decongestant (e.g., pseudoephedrine 30mg every 6 hours).
Best	Detailed ocular exam. Ice pack for 20 min every 1-2 hours for first 48 hours. Monitor for delayed onset of OCS requiring LCC.
Chemical injuries	
Goal	Initiate eye irrigation as quickly as possible to reduce damage to the eye, treat the injury to minimize scarring and loss of vision.
Minimum	Immediate irrigation with IV fluid, sterile water, or clean water with at least 2L of fluid. Remove any particulate matter using a cotton tip applicator.
Better	Continue irrigation until pH=7, verified using urine test strip.
Best	Grade I - erythromycin ophthalmic ointment, cyloplegic drops (cyclopentolate 1%), lubrication with artificial tears.
	Grade II-IV - topical antibiotic drops (moxifloxacin 0.5% eye drops, 1 drop every 8 hours), topical corticosteroid (tobradex or prednisolone acetate 1%, 1 drop every hour while awake), doxycycline 100 mg po every 12 hours, Vitamin C 2g 4 times per day, 100% O_2 for 1hr twice daily.
Preseptal and orbital cellulitis	
Goal	Recognize infection early and start appropriate antibiotics; evacuate suspected cases of orbital cellulitis to an eye surgeon as rapidly as possible
Minimum	**Preseptal**: Moxifloxacin 400mg PO daily or levofloxacin 750mg PO daily. Does not cover methicillin-resistant *Staphylococcus aureus* (MRSA); follow closely for worsening condition. **Orbital**: IV antibiotics: ertapenem, 1 g IV/IO daily or levofloxacin 500mg IV once a day.
Better	**Orbital**: Add nasal decongestant (e.g. Afrin nasal spray twice a day for 3 days) or oral decongestant (e.g., pseudoephedrine 30mg every 6 hours).
Best	**Preseptal**: Trimethoprim sulfamethoxazole DS 1 tablet PO every 8 hours combined with amoxicillin/clavulanic acid 875mg every 12 hours. **Orbital**: Continue IV antibiotics. Monitor vision every 4 hours until evacuation.
Infectious keratitis	
Goal	Prompt recognition and treatment to minimize scarring and loss of vision.
Minimum	Moxifloxacin eye drops 1 drop every 15 minutes for first 2 hours, then 1 drop every hour while awake.
Better	Obtain a culture prior to beginning treatment for sight-threatening keratitis; intense loading dose of moxifloxacin 0.5% eye drops 1 drop every 5-15 min for the first 30-60 minutes (patient can self-administer loading dose if reliable) after culture obtained; then 1 drop every 30-60 minutes around the clock until epithelial defect is closed; cycloplegic eye drop (cyclopentolate 1%), 1 drop every 8 hours for photophobia.
Best	Collagen corneal shield soaked in moxifloxacin drops for transport (5-10 drops) placed over the corneal infiltrate.

Angle-closure glaucoma	
Goal	Prompt recognition and treatment to decrease intraocular pressure.
Minimum	Diagnose based on signs and symptoms: pain, decreased vision, photophobia, dull or cloudy cornea, fixed mid-dilated pupil, increased IOP by palpation. Acetazolamide 500 mg PO initial dose, then 250mg PO every 4 hours to decrease IOP.
Better	Oral acetazolamide plus topical IOP-lowering eye drops (timolol 0.5%, 1 drop twice a day in the affected eye), antiemetic as needed.
Best	Topical corticosteroid (prednisolone acetate 1%) 1 drop every hour after consultation with eye specialist. IV medication for refractory cases (3% hypertonic saline 250ml IV or mannitol 1 g/kg over 30-60 min).
Multi-trauma/thermal burn	
Goal	Prevent ocular exposure and corneal injury in high-risk patients.
Minimum	Keep the ocular surface from drying out using lubricants: sterile petrolatum or methylcellulose drops (do not substitute a non-ophthalmic lubricant). For burns, erythromycin ophthalmic ointment or sterile petrolatum every 2-4 hours.
Better	Horizontal taping of eyelids to protect eyes. Evaluate the eyes and instill a lubricant every 8 hours.
Best	Conduct a detailed ocular exam and cover eyes with food grade polyethylene film to protect eyes.
Surgilube should never be instilled into the eye as a lubricant due to corneal toxicity. When used for ultrasound examination, place a thin film over the closed eyelid.	

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Orthopaedic Trauma: Extremity Fractures (CPG ID:56)

This guide describes the initial non-surgical and surgical management of extremity fractures and to define care guidelines for fractures of upper and lower extremities.

GOALS

The purpose of this CPG is to describe the initial non-surgical and surgical management of extremity fractures; to demonstrate appropriate application of an external fixator with limited resources in order to stabilize for transport; and to define care guidelines for fractures of upper and lower extremities in the context of the host nation's environment and the options available to different patient groups.

BACKGROUND

The majority of combat casualties sustain musculoskeletal injuries[1,2] and the treatment of fractures and associated soft tissue wounds comprise the majority of Role 2 and 3 orthopaedic procedures.[3] The prevalence of musculoskeletal injury requires that surgeons caring for victims of war must manage extremity fractures in the austere environment. Prior to the development of long bone stabilization, mortality from isolated femur fractures was 87% in WWI and reduced to <8% with appropriate splinting. During the recent conflicts, especially as surgical teams have gotten smaller and more dispersed, long bone extremity fracture stabilization will occasionally take second precedent to other injuries. The cumulative burden of femur fractures can make polytrauma patients sicker; so while resources such as imaging may be limited, early femur stabilization is critical for the overall outcomes. Appropriate wound management and fracture stabilization are the mainstays of treatment and are a critical aspect of the multidisciplinary treatment of combat casualties. While a patient's overall physiology and associated wounds must be considered, the effective stabilization of long bone fractures and appropriate debridement of soft tissue injury contribute to effective resuscitation.

EVALUATION AND TREATMENT

EARLY AND THOROUGH WOUND DEBRIDEMENT

- Prehospital care of extremity wounds is covered in the Tactical Combat Casualty Care guidelines and in the Acute Traumatic Wound Management in Prolonged Field Care CPG, 24 Jul 2017. In general, suspected fractures should be splinted whenever possible once life-threatening injuries have been addressed. Open wounds should be treated as soon as possible with antibiotics; either oral or IV antibiotics are acceptable depending on the situation and the patient's ability to swallow the medication. Traction splints may be utilized for femur fractures, however, are not required and other splinting methods may be more expedient. A pelvic binder is indicated in cases of severe lower extremity injury and may be utilized in conjunction with a traction splint.
- Far-forward medical facilities may not have the capability to perform surgical debridement, but early irrigation with removal of gross contaminants may be possible at any level of care and should be performed as soon as possible after injury.
- During the initial examination, the neurologic and vascular exam of the affected extremities should be carefully documented and the affected extremity evaluated for signs of acute compartment syndrome (ACS). Accurate documentation for the next role of care is necessary to determine any evolution of ACS or neurovascular injury.
- A thorough irrigation and surgical debridement should be performed as early as possible.[4]
  - Remove debris and devitalized tissue.

- Bone fragments without soft tissue attachment (i.e. muscle, periosteum) or that are easily removed, should be excised with the exception of large articular fragments.
- All viable tissue should be preserved in order to afford receiving physicians the greatest number of reconstructive options.
- Tag transected nerves and tendons to facilitate identification of structures during reconstruction.
- Treat open fractures with prophylactic antibiotics, primarily 1st generation cephalosporin and tetanus toxoid as soon as possible.[5-9] While there currently is no evidence to support broader spectrum antibiotics, Gram negative organisms are commonly cultured initially and during the treatment of subsequent infection.[10] The use of topical antibiotics is becoming more prevalent and has been shown effective in preventing subsequent infection.[11]

FRACTURE STABILIZATION

1. Fracture instability, especially long bone, can compromise effective patient resuscitation due to ongoing hemorrhage, continued soft tissue damage and respiratory splinting from increased pain. This leads to increased cytokine release, inflammatory response, and shock.[12-15] Early stabilization of femoral shaft fractures is associated with decreased pulmonary complications (including acute respiratory distress syndrome), ICU time, hospital days and mortality and others.[16-19] Long bone stabilization is an important part of early damage control surgery by stabilizing both anatomy and physiology, and is required in the setting of a temporary shunting or definitive vascular repair. Splinting may be the only far-forward option for fracture stabilization and affords the receiving surgeon the greatest number of surgical options. Splinting also may be the most appropriate intervention for low energy fractures and those in the upper extremity and distal lower extremity such as wrist, hand, humerus, elbow, ankle, and foot fractures. An appropriate splint can be effective in temporizing any suspected or known fracture or soft tissue injury until more appropriate stabilization or imaging is available.

2. Open wounds should be addressed first and the status of the underlying wound as well as the date and time of the most recent debridement and irrigation should be documented on the splint itself. If the patient is to be transported, splints must be suitable for the mode of transportation and acceptable within limits of passenger space. Caution should be utilized so splints are not constrictive/circumferential or predispose to compartment syndrome, especially prior to long evacuations. Splints should immobilize the joint above and below the fracture and should have adequate padding at pressure points to prevent soft tissue injury. Splints are intended to limit further injury and are not meant to be definitive treatment. Anatomic reduction may not be possible or necessary for initial splinting of fractures, but a restoration of overall length and alignment of the limb should be sought. A neurovascular exam, including assessing for compartment syndrome, should be documented pre- and post-splinting with or without reduction attempts, to confirm that perfusion and function remain intact after fracture manipulation.

3. Finger and hand injuries may be immobilized with standard splinting methods. Forearm and elbow injuries are best splinted with a long arm posterior splint or a sugar-tong splint. Humerus and shoulder fractures are best immobilized using a sling and swathe or coaptation splint, ensuring there is enough padding at the axilla. Long leg splints for tibia fractures and below the knee splints for

ankle and foot fractures provide adequate stability for transport. Ensure the splint padding allows access for limb compartment.

EXTERNAL FIXATION

1. Due to logistical constraints and concern for infection, internal fixation is not recommended in most austere settings where evacuation to higher levels of care is possible. Surgeons should be well versed on external fixator placement for long bone and periarticular fractures.

   In the setting of concomitant vascular injuries requiring repair or shunting, the orthopaedic surgeon and general surgeon should discuss the sequence of external fixation application (before or after the vascular procedure) considering the following:

   - Ischemia time
   - Degree of deformity in the fractured extremity, specifically the amount of shortening, angulation, mal-rotation, and instability across the fracture site
   - Surgeon comfort level and experience affecting speed of external fixation application
   - Indications to proceed directly to arterial repair versus need for initial shunting

   Benefits of early vascular shunting or repair include reduced ischemia time and possibly reduced need for distal limb fasciotomies, while early fracture stabilization helps re-establish limb and vascular length across the site of injury as well as restore tissue planes for dissection and exposure. The treating surgeons should be mindful of the effects of restoring limb length and alignment on the vascular shunt/repair and plan their interventions to avoid disruption of restored blood flow while effectively stabilizing the limb.

2. External fixation affords adequate fracture stabilization to minimize additional soft tissue trauma and can provide easier access for wound care and re-evaluation for neurovascular injury and ACS. Early fracture stabilization may blunt inflammatory mediators associated with fractures in poly-trauma[12,18] and can be rapidly applied in the multiple injured patient or in a mass casualty situation. Stability afforded by external fixation is also beneficial for pain control and ease of transport, and minimizes the need to manipulate the injured limb during transport and at each higher role of care.

3. External fixation in the austere environment is performed within the constraints of limited equipment and the lack of available fluoroscopy. Surgeons should be familiar with extremity bone and neurovascular anatomy in order to safely apply an external fixator for initial stabilization without the aid of fluoroscopy. Otherwise, splinting should be used for temporary stabilization. Specific portable external fixation kits designed for military use include self-drilling and self-tapping pins that use hand-powered drills for advancement into the bone. External fixation has been shown to be safe in the austere environment when performed at Role 2 and Role 3 facilities.[20] However, caution is advised in attempting external fixation when no basic radiographic imaging is available to identify the fracture pattern, particularly for closed fractures where the facture pattern cannot be visualized or palpated through an open wound. In this case the limb should be splinted without traction and the patient moved to a level of care that has X-Ray capability.

4. External fixator stability is improved by increasing bony apposition at the fracture site, placing the connecting bars as close to the skin as is deemed safe, increasing the distance between pins in each fracture fragment, and using the largest diameter pin possible (typically, 5.0 mm pins in long bones).

Two appropriately placed pins; above and below fracture fragment should provide sufficient stability and will allow receiving surgeons the most options for definitive fixation. Consider the skin incisions for future internal fixation plans when choosing pin sites.

5. The following guidelines allow the safe and effective placement of fixation pins in the austere environment, without the assistance of fluoroscopy but with some basic imaging of the fracture pattern available prior to pin placement.[21] Pins should be placed both "near and far" from the fracture in both major bone fragments. The fracture ends in a closed fracture can be estimated by palpation/manipulation of the bone. One pin in each main fracture fragment should be placed typically 2-3 cm away from the fracture end to improve stability. Pins placed too near the fracture can decrease the external fixator's ability to maintain stability if the pin only captures one bone cortex or is placed in fracture lines that are not grossly apparent. To place each pin, make a longitudinal incision approximately 1 cm in length at the planned pin site and bluntly dissect down to bone. The incision should be generous enough to accommodate the entire width of the pin, as trapped or tented skin contributes to skin irritation and pin tract infection, ultimately leading to pin loosening. Load the pin in either a powered drill or manual driver and place the pin into the incision until the pin meets bone. The pin tip can be used to palpate the edges or curve of the bone so that the central portion may be identified. After broaching the near cortex, hand advancement of the pin should be used to allow the surgeon to feel the far cortex, which is identified by encountering increased resistance while turning the pin. Engaging pin threads across the far cortex provides ideal stability. If intraoperative imaging is available, pins should be advanced until the drill tip is fully past the far cortex. If fluoroscopy is not available, manual advancement 6-8 full turns after reaching the inner surface the far cortex should provide sufficient engagement of the pin. Surgeons must always be aware of limb anatomy as excessive pin advancement can put neurovascular structures at risk.

6. The "far" pins should be placed as far from the fracture site as deemed safe. Intercalary fragments of segmental long bone fractures typically do not require pin fixation, and single pin fixation in these smaller fragments likely does not add to construct stability. Clamps designed to connect the pins and bars are available in the equipment sets, and the pin clamp may be used as a drill guide for appropriate placement of incisions between pin sites. However, using these clamps limits the potential distance between pins in a fracture segment and off-axis pins may not engage in the clamp sufficiently to the detriment of construct stability. External fixators may be placed to span joints if the fractures is near a joint or extends into the articular surface (knee, elbow). (Figures 1, 5, 6)

7. After placing pins, the pins in each fragment can be secured to each other with a pin clamp and tightened. Modified bars are then secured into each pin clamp, and long bars connect to the modified bars of each pin clamp/fracture fragment by using "bar-to-bar" connectors. One bar spanning each fracture fragment is often sufficient for fracture stability. If bar length is too short to span the fracture site, then 2 bars can be connected by a "bar-to-bar" clamp to gain the necessary length. The overall goal of any construct is to restore length and overall alignment of the limb by establishing a provisional reduction of the fracture (thus improving stability), reduce intracompartmental volume to allow tamponade of bleeding, and to restore vascular flow by "unkinking" vessels. Without fluoroscopy, simple longitudinal traction while grossly restoring coronal and sagittal alignment is sufficient for initial stabilization. When spanning the knee, the fixator should be tightened with slight knee flexion. (See Figure 1 below.)

8. Pins can be dressed with Xeroform or similar material and gauze, with Kerlex wrapping of the pins to provide stability to the skin. No formal pin care is recommended, especially in this acute phase, as

formal cleaning protocols have failed to demonstrate improvement in pain, stability, or complications.[22]

Figure 1. Spanning external fixation across the knee joint

LOWER EXTREMITY

Femur: Given the medial and posterior location of neurovascular structures in the thigh, an anterolateral or lateral approach can be used with little risk to neurovascular structures. At the distal third of the femur, however, care should to be taken to avoid over-penetration of the posterior cortex, as this risks injury to the popliteal artery. Anterior pins placed in the distal femur should begin 7.5 cm above the superior pole of the patella to avoid inadvertent intraarticular placement.[23]

Figure 2a. Femur pin

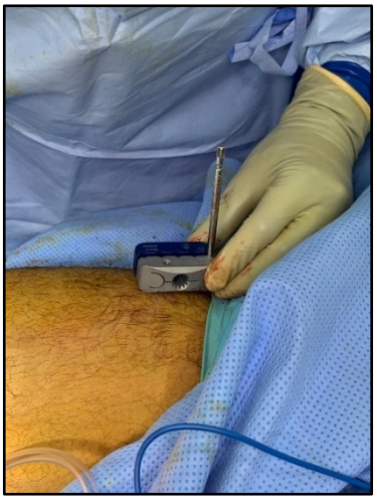

Figure 2b. Knee spanning fixator of right knee.

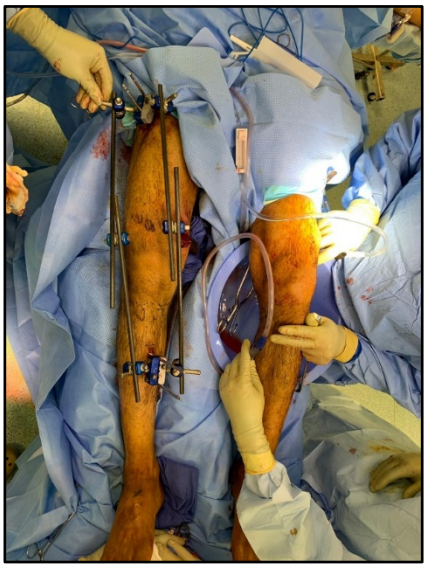


Knee: For distal femur and/or proximal tibia fractures including those involving the articular surfaces, a knee spanning fixator is most appropriate. Two pins each in the intact femur and tibia can be connected by bars. To maximize stability of this longer construct, good pin spread and/or multiple bars should be considered. As with other long bone fractures, longitudinal traction is used to correct coronal and

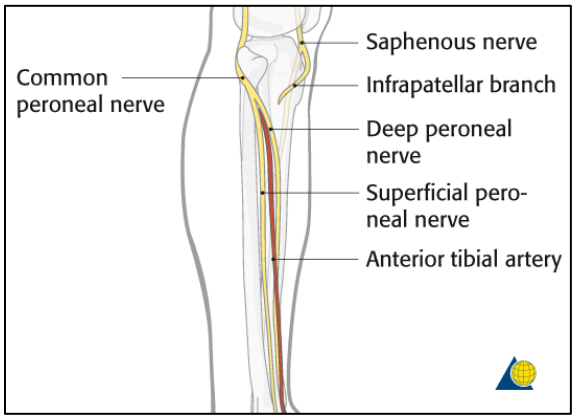
sagittal alignment. The fixator should be locked with the knee in flexion. A posterior slab, short leg splint can be helpful to control ankle plantarflexion and provide additional soft tissue rest and pain control as the gastrocnemius muscle crosses the knee joint.

Tibia: The neurovascular bundle runs along the bone's posterolateral surface. This leaves the anteromedial surface free for safe pin placement. The thin layer of subcutaneous tissue overlying the bone makes this surface easily palpable along its entire length. The direct anterior tibial crest should be avoided as it is significantly thicker than the rest of the bone, and pin placement is difficult even with a power drill. Pins should be placed about 1 cm medial to the anterior crest to avoid the crest as excessive drilling can result in thermal necrosis, pin loosening and eventual infection.

Figure 3. Tibial pin placement

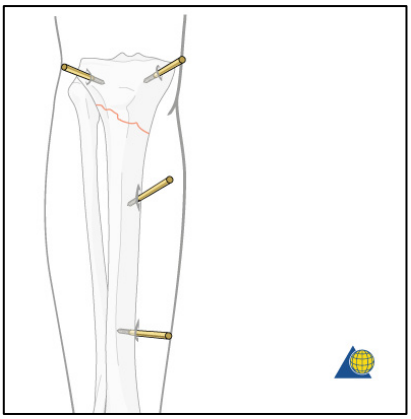
Figure 3a. External view of tibia pin placement

Figure 3d. Lateral view of tibia



Lateral view of tibia showing location of neurovascular structures to avoid during tibial pin placement. Structures are posterolateral and are easily avoided with placement of pins on anteromedial face of tibia.

Figure 3e. Anterior view of tibia with pins



Anterior view of tibia showing potential pin placement for a proximal tibia fracture. A knee-spanning fixator is also an appropriate option in this case.

Source: Courtesy of Marcel Erismann, Senior Medical Illustrator, AO Foundation

Fibula: External fixation of the fibula is not indicated despite any amount of associated tibia or soft tissue injury.

Ankle: To stabilize the ankle (typically in the setting of an unstable distal tibia fracture), two pins should be placed in the tibia proximal to the fracture site and be connected to a centrally-threaded

transfixation pin (or pins) placed through the calcaneus using a medial-to-lateral approach to avoid injury to the neurovascular bundle located just posterior to the medial malleolus. (Figure 4a below) While a 4 mm pin can be placed in the first metatarsal to control ankle dorsiflexion, stable placement can be difficult and the tibialis anterior tendon at the base of the bone can be at risk. A calcaneal pin is more easily placed, and sufficient ankle dorsiflexion can be maintained with the addition of a posterior slab splint as necessary. Talar neck pins, with appropriate anatomic knowledge, can be useful to stabilize the distal tibia, particularly if a calcaneal fracture is present that precludes transfixation pin placement.

Figure 4a: Pin placement for ankle stabilization

Source: Courtesy of Marcel Erismann, Senior Medical Illustrator, AO Foundation

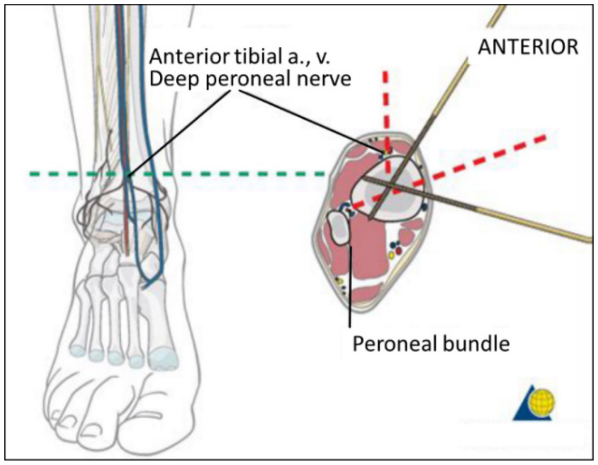


Figure 4b. Delta frame

Example of an ankle-spanning "delta frame" with 2 transfixation calcaneal pins necessary to connect bars to the pin clamps when no pin-to-bar connectors available. Two pins may lessen the need for a posterior splint but a splint can be useful for additional soft tissue protection and to prevent forefoot plantarflexion. Note the addition of the two short "kickstand" bars posteriorly that decreases direct pressure on the heel.

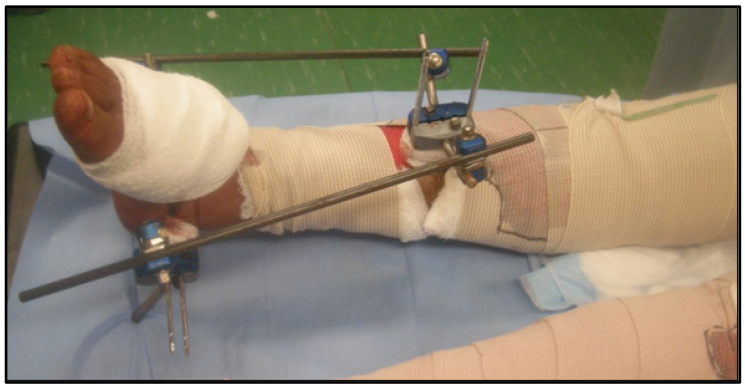

Figure 5. Use of spanning external fixation to stabilize blast injury to lower extremity

Basic radiographic imaging obtained prior to procedure demonstrated comminuted distal 1/3 femoral and mid-shaft tibial fractures. A spanning external fixator was placed across the knee joint, and an expanded "delta frame" external fixator uses the proximal tibial pin clamp site to stabilize the segmental tibial fracture.

Figure 5a: Comminuted distal femoral fracture

Figure 5b: Mid-shaft tibial fractures

Figure 5c: External fixator

Figure 5d: Delta frame external fixator

UPPER EXTREMITY

Splinting of the upper extremity may be preferable over external fixation especially for isolated injuries. Upper extremity external fixators can be complicated by the proximity of neurovascular structures. Familiarity with upper extremity anatomy and careful dissection before pin placement can lessen the chance of injury.

Humerus: External fixation of the humerus can be particularly risky due to the intimate relationship with the neurovascular structures. External fixation should be reserved for instances of severe soft-tissue destruction or when associated vascular injury requires shunting or repair. In general, the lateral and anterior surfaces are safer for half pin insertion. Over-penetration of the medial cortex places the neurovascular bundle at risk for injury. For fixation around the elbow, half pins are placed proximal to the lateral epicondyle through an open approach. The incision should be of sufficient length to positively identify the radial nerve as it traverses anteriorly between the biceps and brachioradialis about 10-14 cm proximal to the lateral epicondyle. After pin placement, the incision is closed around the pins.

Ulna: The dorsal surface of the ulna is easily palpable along its entire length. The ulnar nerve is located radial and volar to the bone making the palpable surface an ideal site for pin placement. 5mm pin diameters can be too large based on the diameter of the bone, and 3-4mm pins should be used instead.

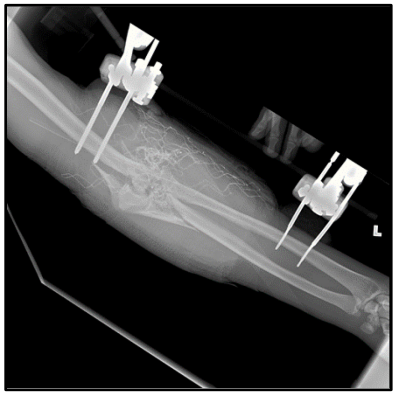
Radius: At the proximal third of the radius, the dorsal surface is obscured by the variable course of the posterior interosseous nerve. Accordingly, pin placement should be limited to the radial surface of the more palpable middle and distal third of the radius to avoid injuring the radial nerve motor branches. An incision allowing sufficient dissection to expose and retract the branches of the superficial branch of the radial nerve and underlying tendons is necessary to avoid entrapment or damage of these structures. As with the ulna, 3-4mm diameter pins are often more appropriate due to the size of the radius at the location the pins are being placed.

Figure 6. Pin placement in the forearm.

Upper extremity external fixator applied for open comminuted intra-articular distal humerus fracture with associated brachial artery injury from a high velocity gunshot wound. An expeditious spanning external fixator was used with smaller pins placed in the distal radial third of the radius followed by arterial shunting of the brachial artery, followed by debridement, and irrigation of the wounds. Note: The distal radial pin was adjusted after postoperative radiograph for over penetration.

Figure 6a: Distal Humerus Fx Brachial Artery

Figure 6b: X-ray of distal radial pin



HOST NATION CASUALTIES

One particular challenge for medical providers in an under-resourced host nation is the likelihood of treating individuals with unknown follow-up care. Low-energy, closed fractures may be treated definitively with a splint or cast. Plaster often is preferred to fiberglass for casting, as cast saws may not be locally available. Certain low-energy fractures may warrant open reduction and internal fixation or closed reduction and percutaneous pinning. External fixation is also an option for initial stabilization if transfer to a host nation facility is possible, or tempo of casualties allows for delayed internal stabilization. External fixation can be used successfully to definitively treat fractures but requires careful pin placement, long term construct stability and close follow up that may not be possible. In the setting of high-energy wounds with extensive soft tissue loss, a staged amputation that may be definitively closed in a short period of time must be considered. Unavailability of prolonged and advanced surgical care make limb salvage challenging.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Patients with long-bone fractures of the extremities (femur, tibia, humerus, radius, ulna).

INTENT (EXPECTED OUTCOMES)

1. All patients in the population of interest have a neurovascular exam documented at every role of care.

2. All patients in the population of interest have fractures stabilized (splinted or external fixator placement) prior to transport from the first surgical capability.

PERFORMANCE/ADHERENCE METRICS

- All long-bone extremity fractures are stabilized by splinting or external fixation prior to movement from a surgical capability.
- Neurovascular examination is documented for all extremity fractures.
- Casualties with fractures and vascular injury in the same extremity (i.e. vascular injury associated with fracture) who underwent vascular shunt or vascular repair also received external fixation.
- Number and percentage of patients in the population of interest who have a neurovascular exam documented at every role of care.
- Number and percentage of patients in the population of interest who have fractures stabilized (splinted or ex-fixed) prior to transport from first surgical capability.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed every five years; additional PI monitoring and system reporting maybe performed as needed.

The system review and data analysis will be performed by the JTS Chief and the PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

ACKNOWLEDGMENTS

The JTS extends a special thanks to the voting members of the JTS Committee on Surgical Combat Casualty Care for their contribution to the development and publication of this clinical practice guideline.

APPENDIX A: GUSTILO CLASSIFICATION OF OPEN FRACTURES

Gustilo Classification of Open Fractures

I	Low-energy clean wound <1 cm with minimal soft tissue injury and comminution
II	Wound >1 cm with moderate soft tissue damage and comminution. Soft tissue component often defined as disruption <10 cm without periosteal stripping. High-energy wound with skin wound <10 cm involving extensive software tissue destruction, segmental fracture with displacement or bone loss, high degree of contamination, and vascular injury.
IIIa	Fracture wound >10 cm with crushed tissue and contamination but usually with adequate soft tissue coverage or any size open wound associated with a segmental fracture (2 or more major fracture lines with intercalary fragment(s)).
IIIb	Fracture wound >10 cm with crushed tissue and contamination having inadequate soft tissue cover associated with periosteal stripping and often requiring transfer of rotational or vascularized tissue for soft tissue coverage.
IIIc	Open fracture associated with a major vascular injury that requires repair for limb salvage.

APPENDIX B: EX-FIX GUIDE FOR THE NON-ORTHOPAEDIC SURGEON

The purpose of an external fixator ("ex-fix") is to provide a temporizing measure to hold broken bones (usually the femur or tibia) in a reasonable position until further surgery can be performed. The ex-fix provides stability to bones that is particularly important in transfer situations in a combat zone, takes pressure off the surrounding soft tissue and joints, and provides pain relief to the patient.

There are two main types of external fixator constructs:

1. Both sets of pins go in the same bone segment.
2. Joint-spanning external fixator: one set of pins goes in one bone, and the other set goes into the adjacent bone (e.g. knee-spanning external fixator consists of pins in the femur and the tibia). These are typically performed when the fracture occurs near a joint.

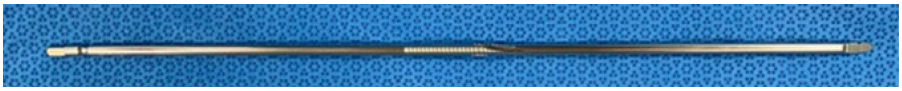
The basic construct consists of the following components:

1. **Pins:** stainless steel pins that are drilled into bone, either on power or by hand. The tips of the pins are threaded to prevent them from backing out of bone.
   a. 5mm pins are typically used for the femur and tibia.
   b. The drill tip (circled) of the pin should be advanced through the bone to allow full engagement of the threads.

   Figure 1

   c. 4mm pins are typically used for the upper extremity and foot. A centrally-threaded (transfixation) pin may be placed through the calcaneus.

   Figure 2

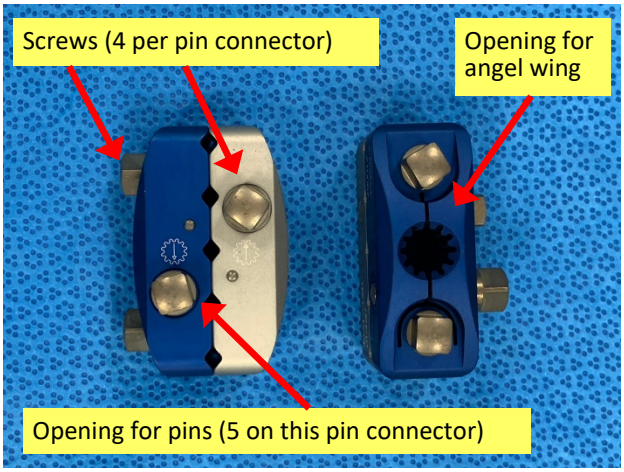


2. **Bars:** rods that connect to pins, or to other bars, via clamps. Modern bars are typically made of carbon fiber and are 11mm in diameter.

   Figure 3

3. **Pin connectors (AKA pin clamps):** blocks that allow two pins to be coupled together and provide an anchor point for attachment of angel wings. These contain screws that are tightened down to allow pins and angel wings to be locked into place.

Figure 4

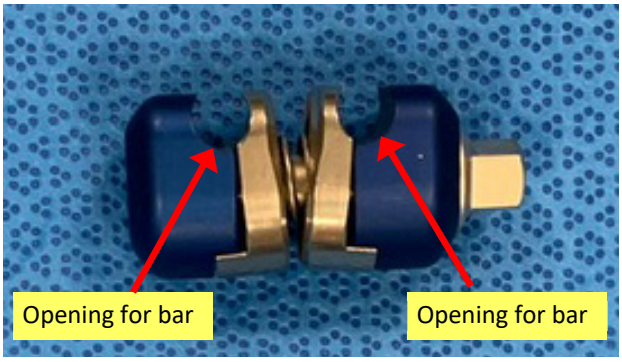


4. **Angel wings (AKA posts):** tiny bars that attach directly to pin connectors and allow for placement of bars via bar-to-bar clamps. These are optional but preferred by the authors for ease of use.

Figure 5

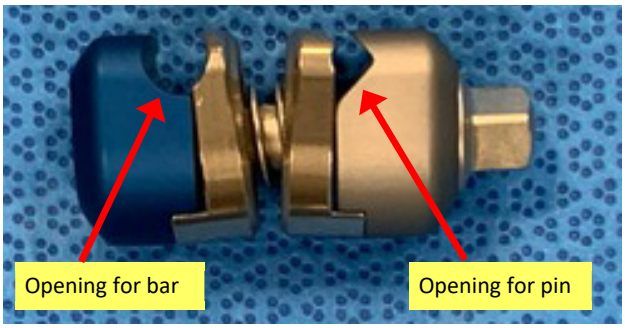
5. **Bar-to-bar clamps:** clamps consisting of two openings, one for each bar. These either attach the angel wings to a bar or, if more length is needed on the external fixator, attach two bars to each other.

Figure 6



6. **Pin-to-bar clamps:** clamps consisting of two openings, one for a bar and one for a pin. These are used in lieu of angel wings and allow the pin to be coupled directly to the bar.

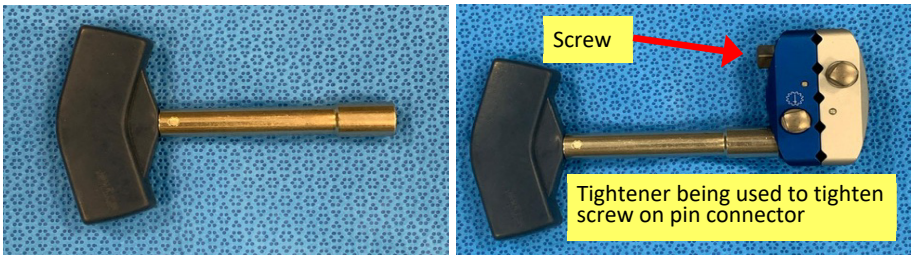
Figure 7



Instruments needed to place external fixator:

1. **Scalpel:** To make stab incision for each pin, no greater than 1cm.
2. **Drill:** Can be either hand drill or on power.
3. **Pin chuck:** May need to be tightened by hand with chuck key depending on system.
4. **Tightener:** Tightens screws on pin connectors and clamps to secure position of pins and bars.

Figure 8



Sterile Field Kit Components

Commercially available sterile field kits allow for placement of an external fixator by hand and typically consist of the following components:

1. **Scalpel**
2. **Mosquito clamp**
3. **Pins**
4. **Bars**
5. **Manual drill-brace**: Serves dual function as hand drill as well as tightener for clamps; each end is labeled for reference (“pin end” and “clamp).
6. **Bar-to-bar and/or Pin-to-bar clamps**
7. **Pin connectors:** Not available in every kit. May come pre-assembled with angel wing.

Basic principles:

1. Two pins (at least) are required on each end of the fractured bone.
2. Pins should avoid immediate proximity to the fracture site (at least 2-3 fingerbreadths away).

3. The external fixator is a tool to reduce fractured bone. Try to restore length and gross alignment.

Minimum Supplies: 4 threaded pins, 2 pin connectors, 2 bars, 2 angel wings (4 suggested), 4 bar-to-bar clamps. *Note: Fluoroscopy is beneficial but not essential.*

Step-By-Step Instructions

(Associated photos for a knee spanning external fixator)

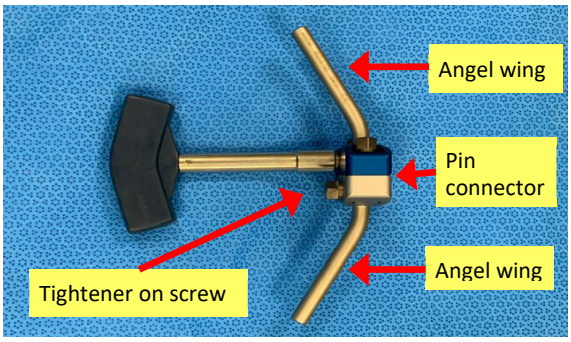
Pin Placement

1. Identify external fixator pin sites as described above, taking care to remain in safe zones.
   - **Femur:** Anterior or anterolateral
   - **Tibia**: Just medial to anterior tibial crest (ridge)
   - **Calcaneus (heel):** 1-2 fingerbreadths in front of (anterior) and above (proximal) to the posterior corner of the heel. Drill centrally-threaded pin from medial to lateral to avoid posterior tibial artery.
2. Start either proximal or distal to fracture.
3. Identify 1st pin site, use scalpel to make stab incision (7-10mm).
4. Use a blunt hemostat to dissect down to bone (keep tips of hemostat closed).
5. Insert pin perpendicular to bone (Figure 1).
   - **Pearl**: To drill the tibial pins, it can be helpful to start drilling perpendicular to the bone and create a divot without going all the way through the cortex, then redirect your hand so it is pointing toward the floor. This may help avoid slippage of the drill.
6. Place pin bicortically—when using a power drill to insert pins be wary of excessive depth of the pin that can damage deep structures. If inserting by hand and/or without power, once the far cortex is engaged (when increased resistance is felt as the pin is turned), advance the pin an additional 6-8 full turns to reach a safe depth. When fluoroscopic imaging is available, placing pins with power is safe and effective. Hand-inserted pins can be adjusted at follow on facilities when needed.
7. If the pin clamps are going to be used, slide pin connector over 1st pin to template location of 2nd pin and mark skin with pin or knife (Figure 2). If clamps are not available or desired, placing the pins in any safe location is possible followed by connection to bars with pin-bar or combination clamps.
8. Repeat steps 3-6 for 2nd pin. Placing the pin parallel to the first can reduce the complexity of the fixator, but off-plane pins can increase stability. Pin placement should be decided based on the associated anatomy, fracture and soft tissue injury patterns and fixator stability (Figure 3).
9. Move to proximal (or distal) pin site and repeat steps 1-8 (Figure 4).
10. Tighten down the screws securing the pins of the proximal and distal pin connectors, ensuring there are 2-3 finger-breaths between the pin connectors and the skin. This is important because swelling will often occur and may lead to skin compromise if the skin is too close to the pin connector. Putting the pin connector too far from the skin, however, will decrease the stability of the construct (Figure 5).
11. If fluoroscopy is available, confirm safe, bicortical position of all pins. The drill tip of the pin should be advanced to a depth allowing full engagement of the cortex with the threaded portion of the pin. A few of the threads of the pin should be penetrating through the second cortex.

External fixator Assembly

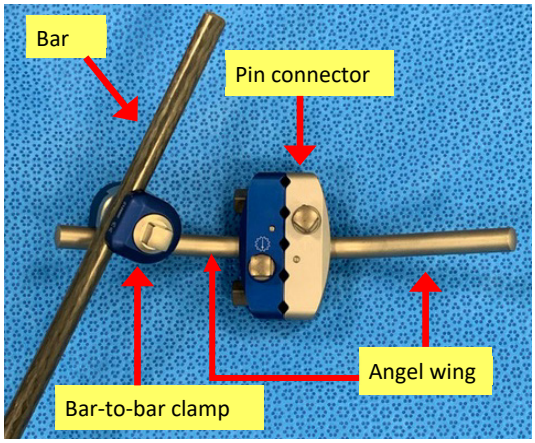
1. Place angel wings onto pin connectors and tighten all components into place with the hand tightener; this includes tightening all screws of the pin connector so that both the pins and the angel wings are secured. (Figure 5)

Figure 9



2. Loosely connect one bar on each angel wing both distally and proximally (If there is only one angel wing proximally and distally, two bars can be placed on the same angel wing to maximize stability).

Figure 10



Additional bar(s) may need to be placed on each side and connected to the other bars via bar-to-bar clamps for joint-spanning external fixatores in particular (Figures 6-9).

3. Apply longitudinal traction to restore length and correct the coronal and sagittal alignment of the limb ("make the leg look like a leg"). If fluoroscopy is available, the reduction can be optimized, but an anatomic reduction is not required. Bony apposition improves stability, but can be difficult to maintain with damage control fixators and quickly restoring overall alignment without delaying additional treatment or transfer in the acute phase is preferable.
4. Tighten all components (Figure 6 and Figure 7).
5. Confirm clinical alignment, as well as radiographic alignment if fluoroscopy is available.
6. Dress pins with petroleum gauze (if desired) and Kerlix wrapping between skin and pin connector. (Figure 8 and 9).

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Pain, Anxiety and Delirium (CPG ID: 29)

This CPG will delineate specific treatment guidelines for pain, anxiety and delirium (PAD) between Role 1, Role 2, Role 3 and higher echelons of care, with an emphasis on Role 3.

SUMMARY OF CARE

1. Pain is universally present in combat casualties and an obligatory part of trauma care.
2. Adequate pain control is an essential part of care from point of injury to continental United States (CONUS) care; it has been shown to reduce the development of chronic pain syndromes and reduce the incidence of post-traumatic stress disorder.
3. Prior to escalating any treatment for pain, consider other potential physiologic etiologies.
4. Orders for the treatment of pain and anxiety should include set goals and the minimum amount of medication necessary to achieve the goals should be used.
5. The Acute Pain Service (APS) should be established and be an integral part of casualty care starting at the theater hospital (Role 3 care).
6. The primary mission of the APS is the provision of effective pain control as well as the treatment and prevention of anxiety and delirium in any injured patient. Standardized and validated scoring systems should be used (see appendices) for assessment and to guide therapies.
7. An APS should include a tracking system that lists all patients on the acute pain service, their injuries and therapeutic interventions along with treatment plan comments.
8. Refer to Table 1 in Appendix A for overall pharmacologic treatment guidelines for PAD.
9. See Appendix H for a sample order set including medication options and dosing.
10. Intermittent dosing of analgesics and anxiolytics should be instituted prior to continuous dosing and continuous drips should be stopped daily to obtain a reliable physical examination and to perform a spontaneous breathing trial in ventilated patients who are potential candidates for extubation.
11. In casualties with injuries that predispose them to compartment syndrome, the decision to use regional anesthesia must be carefully considered if the patients have not previously undergone fasciotomies. Regional anesthesia must be closely monitored in order to not mask a compartment syndrome.

GOALS

This CPG provides an evidenced based framework for the management of pain, agitation/anxiety and delirium (PAD) in injured combat casualties. It is a moral, medical, and operational imperative to provide state of the art pain services to combat casualties, in so forth reducing the incidence of chronic pain syndromes, PTSD, and long-term narcotic dependency. This process begins at the point of injury and Role 1 facility. As the casualty moves along the care continuum, pain and anxiety must continue to be addressed with the increasing capabilities inherent to the military Medical Treatment Facility (MTF). In this CPG, emphasis is placed on Role 3 care, as this is the first MTF that typically is equipped with robust treatment options. Optimal analgesia is a team effort and should be coordinated by the trauma surgeon, the Acute Pain Service (APS) consultant, and the critical care consultant in conjunction with the bedside nurse who ultimately delivers therapy and monitors the adequacy of it. This CPG will address the need for an APS at Role 3 care.[1-3] The APS will be introduced as a necessary adjunct to the Trauma Team. This multidisciplinary collaboration will assess analgesia needs throughout Role 3 care based on injury complexity, trauma burden, risks for coagulopathy / thromboembolic events, anticipated number of surgical procedures, evacuation plan, logistical constraints, and practitioner expertise. It is also important to recognize that pain control should be optimized as a priority over sedation and that the principle of "analgosedation" (i.e. analgesia based sedation) is a viable solution for critically injured casualties.[4]

This CPG will also delineate specific treatment guidelines between Role 1, Role 2, Role 3 and higher echelons of care. Role 1 care guidelines are incorporated from the Department of Defense Committee on Tactical Combat Casualty Care recommendations.

BACKGROUND

Pain is universally present in combat casualties. Ensuring that critically injured patients are treated for PAD is not only essential in the acute setting but also for preventing potential long-term consequences when they are not addressed appropriately. Beginning with point of injury (Tactical Combat Casualty Care) and continuing through the increasing echelons of care, active management of PAD, encompassing prevention, assessment, and treatment are medically and morally imperative. Given the magnitude of injury burden in our combat casualty population, surgical and life-sustaining treatment priorities may conflict, take precedent or overshadow the assessment and active management of PAD. Guidelines should be established understanding that sound clinical judgment, logistic and personnel constraints, and the operational context may dictate the use of other methods. Adequate early pain control to reduce posttraumatic stress disorder and ongoing pain control is an obligatory part of trauma care. The stress response involves a well-established sequence of physiologic and molecular events that include fever, tachycardia, tachypnea, hypertension, gastrointestinal ileus, hypercoagulability, protein catabolism, immunosuppression, among other undesirable consequences that delay or prevent a wounded warrior's full rehabilitation and recovery.[5,6] Effective pain management requires coordination of all medical providers from the point of injury throughout the echelons of care and the medical evacuation system.

Pain is frequently accompanied by anxiety and delirium in critically injured patients and the medications utilized to treat these conditions may paradoxically prolong or even exacerbate them. A multimodal approach to pain control can reduce the total dosage and duration of narcotics required, minimize or even eliminate complications associated with narcotics and reduce narcotic dependence.[7] Adjuncts such as acetaminophen, ketamine, non-steroidal anti-inflammatory drugs (NSAIDs), continuous peripheral nerve infusions, and continuous epidural infusions greatly increase patient safety and the effectiveness of narcotics while reducing the side effects.

TEAM-BASED MULTIMODAL APPROACH

1. The adoption of a team-based multimodal approach to the management of pain, anxiety and delirium most feasibly commences at the level of Role 3 care and should be continued throughout Role IV and subsequent CONUS care. This multimodal management includes the establishment of an acute pain service (APS) starting at the Role 3 and continuing for the duration of the casualty's care. The physician on the team who has the most, and preferentially extensive, experience in pain management should direct the APS. At the Role 3, the APS is staffed from existing Combat Support Hospital (CSH) assets and should include a physician (usually anesthesiologist) pain consultant, chief pain nurse, and ward pain nurse champions.[1,8,9]

2. The APS personnel should interact directly and frequently with the primary treating service, typically led by a trauma surgeon and/or intensivist. This is best accomplished by including the APS in daily rounds led by the primary trauma team and by incorporating the assessment and plan for pain management as a mandatory component of patient rounds. If is it not feasible to incorporate the APS into trauma rounds, then the APS is responsible for daily pain rounds, pain management consults, and reports to the trauma team leader

3. The APS should be available to all patients that are admitted to the Role 3 theater hospital. The primary mission of the APS is the provision of effective pain control as well as the treatment and prevention of

anxiety and delirium in any injured patient. There are standardized and validated scoring systems for the assessment of PAD; including the:

- DoD/VA Pain Rating Scale (Appendix B and Appendix C)
- Richmond Agitation Sedation Scale (RASS) (Appendix D)
- Confusion Assessment Method (CAM) (Appendix E)

4. The Defense and Veterans Pain Rating Scale (DVPRS) and supplemental questions have undergone, and continue to undergo, validation studies.[10] The DVPRS should be used to assess pain, the RASS score should be used to assess anxiety, and the CAM should be used to assess the presence of delirium. Consider potential surgical and medical causes of increased pain and anxiety prior to treating.

5. The APS should consist of an interdisciplinary team of physicians, nurses and pharmacists and should be available 24/7. In addition to participating in daily trauma rounds, they should be responsible for coordinating pain management plans with the validating flight surgeon, medical evacuation team and the receiving MTF. Additionally it should include a tracking and performance improvement (PI) system that follows all patients on the service listing their injuries, therapeutic interventions and care plan; this should be electronically maintained along the continuum of care.

6. To facilitate implementation and utilization of the APS a 'pain cart' with all of the needed supplies for regional anesthesia should be stocked in the anesthesia area. The regional anesthesia area should have immediate access to Advanced Cardiovascular Life Support (ACLS) medications and intralipid. An ultrasound machine should be available for the APS and anesthesia use to facilitate regional blocks. APS order sets can be utilized and should include pain management goals using the minimum amount of medication in order to achieve patient comfort. The goal for patients with delirium is to achieve a delirium free state as measured by the CAM.

   - See Appendix H for a sample order set including medication options and dosing.
   - See Table 1 in Appendix A for a summary list of recommendations.

PREVENTION

PAIN

Pain, as a product of trauma, cannot be prevented, per se, but there are many mechanisms for minimizing and managing pain. This begins with interrupting the mechanism and treating the injury, which are beyond the scope of this CPG; however, an essential part of long-term pain control is early and adequate intervention at the point of injury.[1,11-13] Pain recognition and assessment should be a routine part of combat casualty management followed by prompt intervention. Early interventions are essential to prevent the psychological and biochemical consequences of pain and pain related phenomenon, and to reduce the risk of chronic pain syndrome.[4] Orders for the treatment of pain and anxiety should include set goals and the minimum amount of medication necessary to achieve the goals should be used. These goals are determined by the need to achieve patient comfort and safety.

ANXIETY AND DELIRIUM

Similarly, the prevention of anxiety, agitation and delirium begin with recognition. All combat casualties are at risk for anxiety, which they may attempt to conceal or not disclose. As with pain prevention, management of the underlying etiology, including pain, hypoxia, metabolic abnormalities, and medications effects are essential principals. Disorientation to place and time as a result of unconsciousness, sedation, and loss of awareness

resulting from hospitalization contribute to PAD. This can be prevented with frequent and systemic efforts at reorientation and maintenance of normal sleep patterns.[4]

Interventions to promote healthy, REM sleep include exposure to bright light or sunlight during normal daytime hours and enforced darkness during normal night time hours. Orders should be written for scheduled periods of minimal or no disruption during normal sleep hours and allowing patients to use earplugs during sleep to minimize noise disruption. Conversely, patients should be provided with hearing aids or eye glasses, as needed, to combat sensory deprivation. Victims of close proximity blast exposure should be presumed to have some degree of hearing loss and undergo an audiology evaluation. Intermittent dosing of analgesics and anxiolytics should be instituted prior to continuous dosing. Patients who require dosing more frequently than every 2 hours should be placed on continuous dosing titrated to their goal.

Efforts to prevent delirium in critically injured patients include Awakening and Breathing Coordination (ABC), non-pharmacologic Delirium (D) interventions, and early Exercise (E) and mobility. The ABCDE's should be incorporated into treatment care plans for all ICU patients starting no later than the Role 3.[4,14] Propofol is an option for short term sedation in acutely agitated patients. It has rapid onset and it is also cleared rapidly. Propofol has been associated with hypotension which may be related to intravascular depletion. It is dissolved in a 10% lipid solution which should be accounted for when calculating calorie requirements. Propofol is an excellent drug for ICU patients scheduled to undergo Critical Care Air Transport Team (CCATT) missions. When used for transport, Propofol should only be administered to intubated patients.

Spontaneous Breathing Trials (SBT) should be performed daily. Physical and occupational therapy (PT/OT) should be initiated as soon as possible or at minimum 72 hours after intubation.[14,15]

There is insufficient evidence that prophylactic administration of antipsychotics to the general intensive care unit, (ICU) population prevents delirium and, therefore, we make no recommendation for it.[16] Benzodiazepines, although potentially useful for control of agitation, may increase delirium and should be avoided or minimized in patients experiencing or at increased risk for delirium.

EVALUATION OF PAIN

Some level of pain is present in all combat casualties. While the pain may be initially masked by the intensity of the situation, the combat medic or when the patient reaches the first level of care should assess the level of pain. Seriously injured patients who are not intubated should be assessed every 1-4 hours for the presence of pain. All patients who are intubated need to be continuously monitored for adequate analgesia. Signs of inadequate pain control in the intubated patient include tachycardia, hypertension and agitation. However – it is imperative that other causes be excluded such as early compartment syndrome, missed injuries, or impending physiologic decline. If the patient is appropriately communicative, then using the DoD/VA Pain Rating Scale (DVPRS) and Supplemental Questions as quantifiers can facilitate evaluation and trends.[3,10] All combat casualties will have a pain score recorded on admission to a Echelon III facility and as part of routine care while in the intensive care unit.

EVALUATION OF AGITATION AND DELIRIUM

The assessment of anxiety, agitation, delirium as well as pain can be complicated by the presence of traumatic brain injury (TBI). TBI, in addition to overall injury burden, and therapeutic interventions can affect the evaluation for agitation as well as impede an accurate neurologic assessment. Moderate to severe TBI patients are at particularly high risk for having atypical and/or paradoxical reactions to both sedating and stimulating agents.[17,18] In addition, the reactions to individual agents and their overall impact on the TBI patient in terms of pain, alertness, agitation, anxiety, and delirium may change drastically over relatively short periods of time as

their injury and cognitive status evolves. The following tools help with pain evaluation: Richmond Agitation Sedation Scale (RASS), and the Confusion Assessment Method (CAM); they are included as Appendices D and E.

TREATMENT OF PAIN: GENERAL INFORMATION

As previously stated pain is a universal symptom of the combat injured patient and must be managed early and effectively. Adequate early pain control has been shown to reduce post-traumatic stress disorder and ongoing pain control is an obligatory part of trauma care. Inadequate treatment results in undesirable consequences that delay or prevent a wounded warrior's full rehabilitation and recovery.

Non-pharmacologic pain therapies should be considered first-line treatment for mild to moderate pain or an adjunct to opioid medications. This includes Battlefield Acupuncture (BFA) when administered by an appropriately qualified clinician and supplies are available. (See Appendix F.)

With regards to specific opioid medications, any opioid available can be titrated to equal effectiveness for achieving desired pain control. This CPG is going to emphasize the use of Ketamine throughout the deployed continuum of care. Ketamine is a very effective analgesic either by itself or as an adjunct to opioid analgesia and can be used to reduce the total narcotic burden.[19,20] Ketamine, in parenteral doses of 0.15-0.3 mg/kg, has been shown to reduce pain scores, total narcotic use, and need for rescue medication when used with morphine for acute pain control.[20]

ROLE 1 TREATMENT OF PAIN

The Role I pain treatment guidelines described here are adopted directly from the most recent protocols developed by the Department of Defense's Committee on Tactical Combat Casualty Care (TCCC), available online at Deployed Medicine. The most current guidelines, with full course material and supporting documentation, is available through a Common Access Card enabled webpage from the Military Health System (https://mhs.health.mil/References/REF_TCCC.cshtml).

Additionally, the *Journal of the Special Operations Medical Association* maintains free access to the current protocols (https://www.jsomonline.org/TCCC.html).[21,22] See Appendix H for a sample order set including medication options and dosing.

Analgesia on the battlefield should generally be achieved using one of three options, per the TCCC triple analgesia protocol. This is an abbreviated presentation of that protocol. The detailed description can be obtained via websites described above.

- **Option 1**, for mild to moderate pain when the casualty is still able to fight should include the TCCC Combat pill pack with acetaminophen and meloxicam given simultaneously.
- **Option 2**, for mild to moderate pain when the casualty is not in shock or respiratory distress, and the casualty is not at significant risk of developing either condition, should include oral transmucosal fentanyl citrate (OTFC) 800 ug. Naloxone (0.4 mg IV or IM) should be available when using opioid analgesics.
- **Option 3**, for moderate to severe pain when the casualty is in hemorrhagic shock or respiratory distress or the casualty is at significant risk of developing either condition, should include ketamine 50 mg IM or IN or ketamine 20 mg slow IV or IO. Ketamine doses can be repeated every 30 minutes for IM or IN and every 20 minutes for IV or IO administration.

Casualties should be disarmed after being given Oral Transmucosal Fentanyl Citrate (OTFC) and always disarmed after receiving ketamine. Documentation of a mental status exam using the alert, verbal, pain, and unresponsive

(AVPU) method should be performed prior to and after administering opioids or ketamine, and recorded on the TCCC Card (DD Form 1380, JUN 2014). Ketamine may be a useful adjunct to reduce the amount of opioids required to provide effective pain relief. It is safe to give ketamine to a casualty who has previously received morphine or OTFC. IV Ketamine should be given over 1 minute.

ROLE 2 TREATMENT OF PAIN

Damage Control Surgery is provided at Role 2. An anesthesiologist and/or certified registered nurse anesthetist will be on staff and in conjunction with the surgeons, will be responsible for perioperative pain management. Role 2's differ in their capability with some consisting of a single operating room bed and a single post-operative ICU bed while others have attached Emergency Care and Post-Operative Holding Capacity.

In the more austere Role 2, pain should be managed with intravenous opioids and ketamine titrated as needed to provide adequate pain control; if dysphoric symptoms emerge with ketamine, then a small amount of benzodiazepine should be administered.

More robust Role 2's will have additional personnel, equipment, and supplies available. At these locations, the capability might exist for peripheral nerve blocks, which could be performed by the anesthesia provider or by the orthopedic surgeon assigned to the unit. Infusion pumps may also be available for continuous opioid infusions in critically injured patients, with dosage titrated as needed to provide adequate pain control. Patients on infusions require close monitoring in an ICU setting. Some of these more robust Role 2's with attached ward holding may have Patient Controlled Analgesia (PCA) pumps that can be used by patients to manage their pain. Pain should be adequately controlled prior to starting PCA; the patient can then use the PCA for self-dosing as needed for pain. The starting doses for PCAs are as follows:

1. Morphine PCA in adults is 1-3 mg with 10-20 minute lockout
2. Hydromophone PCA in adults is 0.1-0.3 mg with 10-20 minute lockout
3. Fentanyl PCA is 15-25 mcg with 10-20 minute lockout.

Patients on PCA require monitoring by nursing staff. Naloxone must be available to treat respiratory distress that may occur secondary to opioids.

ROLE 3 TREATMENT OF PAIN

Regional anesthesia procedures should be performed in a monitored setting where nursing staff is available to help with patient care and provide appropriate recovery services for the patients. The Acute Pain Service (discussed extensively above) should maintain and provide input for standing orders to include:

- Continuous epidural and peripheral nerve catheter infusion and single injection epidural or intrathecal narcotics.
- Intravenous patient controlled analgesia (PCA) Orders. Fentanyl, hydromorphone, and morphine are the narcotic agents of choice. (Meperidine (Demerol) is not an approved compound for repeated PCA dosing as the metabolite normeperidine reduces the seizure threshold.)

Low dose ketamine infusions have profound analgesic effects with very minimal side effects. The anti-inflammatory effects of ketamine may also attenuate the systemic inflammatory response seen in trauma.[13,23,24] Ketamine binds the NMDA receptor and in addition to having direct analgesic properties, it also decreases the total dose of narcotics that is needed for adjuvant pain control.

Ketamine infusions should be made as follows:

- 250 mg of Ketamine in 250 ml of normal saline.
- For patients who are 70 kg or greater and less than 60 years old, start infusions at 10 mg per hour in the setting of acute and neuropathic pain.
- Patients > 60 year old or <70kg should receive 100 micrograms/kg/hour of ketamine in the setting of acute or neuropathic pain.
- Custom orders may be titrated by the attending anesthesiologist or critical care physician.

EPIDURAL CATHETERS

Neuraxial analgesia can be a very effective pain treatment in the injured warfighter, but special care must be taken to ensure that it is provided safely. Standard preservative free local anesthetics include ropivacaine and bupivicaine. The standard medication for aeromedical evacuation is 0.2% ropivacaine with sufficient volume for 3 days. Patients should be on stable doses of infusions prior to AE transportation. The risk/benefit of epidural placement must be considered in the injured combat casualty who is also at risk for venous thromboembolic events. While all antiplatelet and anticoagulant medications increase the risk of bleeding, low molecular weight heparin (LMWH) use in patients undergoing epidural anesthesia greatly increases the risk of epidural hematoma, which can lead to paralysis. The acute pain service should maintain and provide input for standing orders to include:

1. All catheters should receive a 3 ml test dose of local anesthetic containing at least 1:400,000 epinephrine.
2. Low molecular weight heparin (LMWH) use in patients undergoing epidural anesthesia increases the risk of spinal or epidural hematoma, which may cause long term or permanent paralysis. We recommend against the use of LMWH in AE patients given the increased motion of delivery catheters during patient transport and resulting increased risk for spinal & epidural hematoma formation.
3. Prophylactic LMWH dosing should be held for 12 hours prior to placement of an epidural catheter.
4. Therapeutic dosing should be held for 24 hours prior to placement of epidural catheters.
5. Administration of LMWH should be delayed for 2 hours after catheter removal.
6. The maximum recommended prophylactic dose of LMWH with an epidural catheter in place is 40 mg SQ daily.
7. Twice daily dosing of LMWH is not recommended for patients with indwelling epidural catheters.
8. The initial dose of once daily prophylactic LMWH should not be given until 6-8 hours after catheter placement. Subsequent daily doses should start 24 hours after this first dose.

These recommendations are consistent with the most recent ASRA (American Society of Regional Anesthesia) guidelines for the prevention of epidural hematoma.

***Note**: Given that our patients are transported through a spectrum of care and across thousands of miles, the implementation of regional anesthesia should be integrated throughout the trauma system and must be safe and effective. An anesthesia provider is responsible for the initial placement and dosing of an epidural catheter. Only members of the Acute Pain Service can change the dosing or infusion rate*.

Appendix G is a summary of the American Society of Regional Anesthesia guidelines as they relate to use of LMWH in combat casualties. The ASRA guidelines were originally developed for use of LMWH in the perioperative course.

Additionally, these recommendations change on a frequent basis; https://www.asra.com/ should be consulted for the most current recommendations.

PERIPHERAL NERVE CATHETERS

1. All catheters should undergo a local anesthetic test dose containing 1:400,000 epinephrine.
2. For patients undergoing deep plexus or peripheral block, we recommend that recommendations regarding neuraxial techniques be similarly applied.
3. Each patient should have no more than two catheters and the total dose of 0.2% Ropivacaine should not exceed 20 ml per hour.
4. Regional anesthesia patients should be recovered by standard post anesthesia care unit (PACU) criteria.

Patients with epidurals and peripheral nerve blocks should be held in recovery until they meet standard discharge criteria from PACU and ICU. Patients with peripheral nerve blocks and epidural catheters that have met discharge criteria from ICU and PACU may be managed on the floor. Any patient with an epidural catheter or peripheral nerve block must be closely monitored for signs or symptoms of compartment syndrome (see below). No narcotics will be added to the peripheral nerve block or epidural infusions given the ongoing revision of validation for air transport by the United States Air Force (USAF).

TREATMENT OF ANXIETY AND AGITATION

Given the nature of combat injuries and the environment of care, both agitation and anxiety can be expected and should be preemptively managed. In a patient with normal hemodynamics, propofol is a good option for short-term sedation. **Propofol** does not provide analgesia; it is the most commonly used medication when sedation is required for ICU patients and CCAT transports due to its rapid onset and clearance. It is a $GABA_A$ agonist with rapid onset and clearance. Propofol can cause hypotension and should be used with caution in patients with intravascular depletion. Propofol is dissolved in a 10% lipid solution. It is an excellent drug for ICU patients scheduled to undergo aeromedical evacuation. Propofol should only be administered to patients who have a definitive airway (endotracheal tube, tracheostomy), are hemodynamically stable and are continuously monitored by trained personnel.[4,25,26]

Dexmedetomidine is being used with increasing frequency in ICU patients and occasionally for transport. It minimally decreases respiration, so it can be used for patients on non-invasive mechanical ventilation or sedation for an awake intubation. It has some mild analgesic effects. It should be used with caution in patients with bradycardia or heart block. Dexmedetomidine is a relatively selective alpha-2 agonist; it is a good option for short-term sedation and anxiolysis. Dexmedetomidine has minimal impact on respiratory drive allows for ongoing assessment of the patient's mental status.[4]

Clonidine is an effective drug for treating patients with anxiety and agitation; it is particularly effective for patients with hypertension associated with agitation.[5,27] Clonidine acts as an alpha-2 adrenergic agonist and also has sedative properties that do not result in respiratory suppression. It may also be used for mild sedation and analgesia.[27]

TREATMENT OF DELIRIUM

The typical antipsychotic **haloperidol (Haldol®)** and the atypical antipsychotic **quetiapine (Seroquel®)** are commonly used for the treatment of delirium. Quetiapine can also be used as an anxiolytic; it is particularly effective when used QHS PRN to help regulate sleep in a patient at risk for anxiety and delirium. Both of these drugs may be associated with prolongation of the QT interval potentially resulting in fatal arrhythmias secondary to torsades des pointes. If these drugs are used, the QTc interval should be monitored with an electrocardiogram (EKG) on a daily basis. They should be discontinued if the QTc exceeds 500 msec or the interval increases 60 msec from baseline.[4]

PREVENTING COMPLICATIONS

Medications should be specifically directed and dosed to achieve a defined goal, for example:

- Achieve a pain score of 4 or less
- Maintain sufficient patient consciousness to assess the evolution of injuries by physical exam
- Decrease the need for mechanical ventilation
- Amelioration of symptoms of anxiety, delirium or agitation

BENEFITS OF SEDATION HOLIDAY AND INTERMITTENT MEDICATION DOSING

INTERMITTENT DOSING

Intermittent dosing of analgesics and anxiolytics, as opposed to continuous dosing, has been shown to reduce the duration of mechanical ventilation and intermittent dosing of analgesics and anxiolytics should be instituted prior to continuous dosing. Although many sedative agents are utilized for their short duration of action (e.g. midazolam), administration as a continuous infusion will often result in a prolonged duration of action and effect due to fat storage an accumulation of active metabolites. It is recommended that intermitted sedation be used whenever feasible. For patients who require dosing more frequently than every 1-2 hours, continuous dosing titrated to effect can be used; however, continuous infusions should be converted to intermittent dosing as early as possible.

SEDATION VACATIONS

Daily interruptions of sedation ("sedation vacations") have repeatedly demonstrated reduction in the duration of mechanical ventilation as well as the incidence of ventilator-associated pneumonia.[21] Intermittent dosing and daily sedation holidays prevent the accumulation of active metabolites, which may impede patient assessment for prolonged periods of time.[25,28]

- Continuous infusions should be stopped daily to obtain a reliable physical examination, including neurologic assessment, and to perform a spontaneous breathing trial in ventilated patients.
- Sedation Goals should be assessed every day following sedation holidays and every effort should be made to reduce infusion doses.

CONTRAINDICATIONS TO THE DAILY SEDATION HOLIDAY:

- Intractable intracranial hypertension.
- Hemodynamic instability.
- Inability to adequately oxygenate or ventilate mechanically ventilated patients.

See Appendix H for a **sample order set** including medication options and dosing.

See Table 1 in Appendix A for **suggested management algorithms.**

LOCAL ANESTHETIC TOXICITY

Local anesthetic toxicity is extremely rare in a patient who has an established neuraxial or peripheral nerve catheter. If suspected, all local anesthetic infusions should be immediately stopped. Occasionally the presenting symptom is cardiac arrest. In cardiac arrest, the patient should immediately receive 1.5 ml/kg of 20% Intralipid while receiving chest compressions and other ACLS interventions such as airway management. Repeat the bolus 1-2 times as needed for persistent asystole, pulseless electrical activity or reemergence of hemodynamic insanity. Increase the infusion rate to 0.5 mL/kg/min if hemodynamic instability persists or recurs. Continue the infusion for at least 10 min after hemodynamic stability is restored; discontinue within 1 hour if possible. Another rare symptom of local anesthetic toxicity is seizure. Once again, the infusion should be stopped, seizure should be treated with an anti-seizure medication and the airway should be controlled if necessary. Much more common symptoms of local anesthetic toxicity are tinnitus, anxiety, restlessness, dizziness and blurred vision; in the case of these symptoms, the infusion should be stopped.

1000 ml of 20% Intralipid should accompany patients receiving local anesthetic infusions during transport in the AE System.

NAUSEA

Nausea is a common side effect of both trauma and the medications used to treat pain, anxiety, and delirium. Consider prophylactic treatment whenever possible and treat immediately upon patient report of symptoms. If the patient has recently undergone an emergency general anesthetic or any type of abdominal surgery, then ensuring that they are not at aspiration risk is important prior to medication. If there is a concern for gastric distention or any type of obstruction (functional or mechanical), then the patient should receive gastric decompression with an NG tube in additional to pharmacologic management for nausea.

Ondansetron is a safe antiemetic in the adult population and is increasingly the therapy of choice for acute undifferentiated and trauma-related nausea.[29] It has no effect on consciousness or the respiratory drive; additionally, at the doses recommended for these patients (4-8 mg per dose) has no clinically significant effect on QT interval.[29,30]

COMPARTMENT SYNDROME

Compartment syndrome is a well-described complication of traumatic injury; for the purposes of this CPG, only extremity compartment syndrome will be discussed. Definitive treatment is complete surgical release of the extremity compartments affected. The acute pain anesthesiologist and trauma surgeon should have a detailed discussion regarding patients who are at high risk for compartment syndrome. Pain control may mask the typical early sign of compartment syndrome: increased pain in the compartment. Any patient at risk for extremity compartment syndrome who is awake and has an increased pain medication requirement should be promptly and thoroughly assessed for increased compartment pressure. For patients with regional or neuraxial analgesia affecting an extremity that is felt to be at risk for compartment syndrome, more frequent clinical assessments and monitoring of the extremity are warranted. If the patient is unable to reliably detect and report pain and there are any clinical or examination findings concerning for a compartment syndrome, then bedside assessment of compartment pressures or performance of a fasciotomy should be done promptly. If there is any concern for compartment syndrome, then full compartment release with fasciotomies must be completed prior to aeromedical transportation. Newer monitoring technologies such as near infrared spectroscopy; have shown

some promise in early noninvasive detection of compartment syndrome; however, they are not currently the standard of care.

AIR EVACUATION CONSIDERATIONS

The United States Air Force (USAF) Patient Movement Request (PMR) must state the type of regional anesthesia being utilized. All individuals participating in the care of the patient should have up-to-date training and experience with regional anesthesia, techniques, medications, and equipment. All equipment associated with the use of regional anesthesia must be approved for flight. The current infusion pump system that has been approved by the USAF for air evacuation is the small portable Ambit pump. Ambit pumps should be used for epidural, peripheral nerve catheters, ketamine infusions, narcotic infusions, and patient controlled anesthesia. For all patients receiving regional anesthesia/analgesia, coordinate with the Trauma Chief, Theater Validating Flight Surgeon and Theater CCATT Director prior to any planned fixed-wing tactical (Intratheater) or strategic (Intertheater) transport to ensure patient safety during flight operations.

Patients undergoing prolonged air evacuation are exposed to a multitude of austere environments over a relatively short period of time. CCATT providers recognize that turbulence, weather, temperature, limited patient access and monitoring constraints make it inherently difficult to maintain sedation and analgesia. It may be necessary to empirically increase sedation and pain regimens to maintain a safety margin that protects endotracheal tubes and other invasive devices. This clouds a patient's neurologic exam. Therefore patients with potential intracranial injury (TBI or stroke) who cannot be serially, neurologically evaluated should have intracranial pressure monitors.

In terms of peripheral nerve blocks or epidural catheters, no narcotics will be added to the infusions; the addition of narcotics to these regional therapies changes the validation for air transport by the USAF.

GUIDANCE

- The Military Advanced Regional Anesthesia and Analgesia handbook is an excellent APS reference text for pain care standards (https://medcoe.army.mil/borden-4-specialty-titles).
- Tri-service policies for pain management can be found at https://www.dvcipm.org/.
- Strategic issues on evacuation pain management should be referred by the health care facility American Physical Society (APS) physician to the Defense and Veterans Pain Management Initiative organization (https://www.dvcipm.org/).

PERFORMANCE IMPROVEMENT (PI) MONITORING:

POPULATION OF INTEREST

All injured patients

INTENT (EXPECTED OUTCOMES)

1. Patients in the population of interest have a documented pain assessment at every role of care.
2. Patients in the population of interest in the intensive care unit are screened for delirium daily.
3. Intubated patients will not experience an inadvertent or unplanned extubation.

PERFORMANCE ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have a documented pain assessment at each role of care.
2. Number and percentage of patients in the population of interest in the intensive care unit with documented delirium screen daily.
3. Number and percentage of intubated patients who experience an inadvertent or unplanned extubation.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

All healthcare providers will:

1. Become familiar with the guidelines for the management of pain, anxiety and delirium in critically injured patients.
2. Appropriately manage patients with pain, anxiety and delirium.
3. Provide feedback on these guidelines and suggestions for changes to the CPG to the JTS Director.

The Trauma Chief, Pain Director and Intensivist at each level III facility will:

1. Implement care that is consistent with the intent of this CPG.
2. Monitor adherence with the CPG.

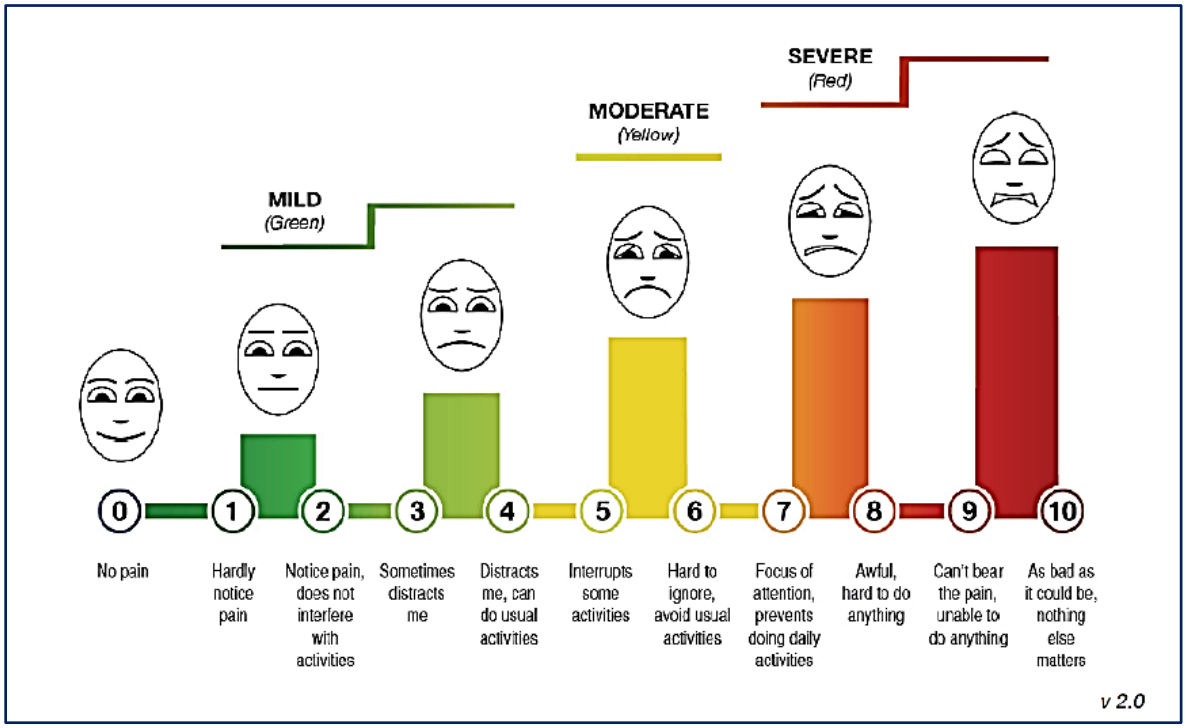
APPENDIX A: PAIN, ANXIETY (SEDATION) AND DELIRIUM GUIDELINES

		Intubated Hemodynamically Unstable or severe ARDS	Intubated Hemodynamically Stable, adequate gas exchange	Not Intubated Stable
		Goals: Minimize pain, patient safety RASS -3 to -4, no sedation holiday, consider paralysis	**Goals: Minimize pain, patient safety RASS -1 to -2, daily sedation holiday or continuously interactive patient**	**Goals: Minimize pain, patient safety RASS 0, continuously interactive patient**
Background	Pain	*Option 1:* Ketamine drip *Option 2:* Intermittent Narcotic (*Option 1 for TBI) *Option 3:* Fentanyl or drip or equivalent if tolerated	*Option 1:* fentanyl drip or equivalent *Option 2:* Ketamine Drip *Option 3:* Intermittent Narcotic (*Option 1 for TBI)	*Option 1*: Scheduled Enteral or Parenteral Narcotic *Option 2:* Intermittent as needed enteral or parenteral narcotic
	Sedation	*Option 1:* Ketamine drip *Option 2:* Intermittent Benzodiazepine *Option 3:* Propofol drip if tolerated (*Option 1 for TBI)	*Option 1:* Propofol Drip *Option 2:* Demedetomidine Drip *Option 3:* Intermittent Benzodiazepines	NA
	Adjuncts	*Consider first:* Axial or regional anesthetic by catheter or injection *Consider also:* – scheduled acetaminophen or paracetamol – gabapentin and/or TCA for amputees		
Breakthrough	Pain	*Option 1:* Intermittent/bolus ketamine *Option 2:* Intermittent/bolus narcotic	*Option 1:* Intermittent/bolus narcotic *Option 2:* Intermittent/bolus ketamine	*Option 1:* PCA *Option 2:* Intermittent as needed enteral or parenteral narcotic
	Sedation	*Option 1:* Intermittent/bolus ketamine *Option 2:* Intermittent/bolus benzodiazepine	*Option 1:* Intermittent/bolus benzodiazepine *Option 2:* Intermittent/bolus ketamine	*Option 1*: As needed enteral or parenteral benzodiazepine
	Adjuncts	*Consider:* – Dim, calm environment, reassurance, music, presence of friends/family – Give bolus and/or adjust dose of axial or regional anesthetic		
Procedural	Pain	*Option 1:* Intermittent/bolus ketamine *Option 2:* Intermittent/bolus narcotic	*Option 1:* Intermittent/bolus ketamine *Option 2:* Intermittent/bolus narcotic	*Option 1:* Planned pre-procedural enteral or parenteral narcotic *Option 2:* Pre-procedural ketamine *Option 3:* Demedetomidine
	Sedation	*Option 1:* Intermittent/bolus ketamine *Option 2:* Intermittent/bolus benzodiazepine	*Option 1:* Increase dose of background propofol +/- propofol bolus *Option 2:* Intermittent/bolus benzodiazepine *Option 3:* Intermittent/bolus ketamine	*Option 1:* Pre-procedural ketamine +/- benzodiazepine *Option 2:* Planned pre-procedural enteral or parenteral benzodiazepine *Option 3:* Demedetomidine
Delirium	Prevention & Management	– Maintain day night cycles – Consider afternoon naps – Consider ear plugs at night – Consider less sedation and avoid benzodiazepines – Prioritize early mobility and patient interaction		
	Treatment		Consider dexmedetomidine for sedation and/or at night for sleep Consider quetiapine	

APPENDIX B: DOD AND VA PAIN RATING SCALE



APPENDIX C : DOD AND VETERANS PAIN SUPPLEMENTAL QUESTIONS

1. Circle the one number that describes how, during the past 24 hours, pain has interfered with your usual ACTIVITY:

0 — 1 — 2 — 3 — 4 — 5 — 6 — 7 — 8 — 9 — 10

Does not interfere — Completely interferes

2. Circle the one number that describes how, during the past 24 hours, pain has interfered with your SLEEP:

0 — 1 — 2 — 3 — 4 — 5 — 6 — 7 — 8 — 9 — 10

Does not interfere — Completely interferes

3. Circle the one number that describes how, during the past 24 hours, pain has affected your MOOD:

0 — 1 — 2 — 3 — 4 — 5 — 6 — 7 — 8 — 9 — 10

Does not affect — Completely affects

4. Circle the one number that describes how, during the past 24 hours, pain has contributed to your STRESS:

0 — 1 — 2 — 3 — 4 — 5 — 6 — 7 — 8 — 9 — 10

Does not contribute — Contributes a great deal

v 2.0

APPENDIX D: RICHMOND AGITATION SEDATION SCALE (RASS)

Score	Term	Description	
+4	Combative	Overtly combative, violent, immediate danger to staff.	
+3	Very Agitated	Pulls or removes tube(s) or catheter(s); aggressive.	
+2	Agitated	Frequent non-purposeful movement, fights ventilator.	
+1	Restless	Anxious but movements not aggressive vigorous.	
0	Alert, Calm		
-1	Drowsy	Not fully alert, but has sustained awakening (eye-opening/eye contact) to voice (≥10 seconds).	Verbal Stimulation
-2	Light Sedation	Briefly awakens with eye contact to voice (<10 seconds).	
-3	Moderate Sedation	Movement or eye opening to voice (but no eye contact).	
-4	Deep Sedation	No response to voice, but movement or eye opening to physical stimulation.	Physical Stimulation
-5	Unarousable	No response to voice or physical stimulation.	

Procedure for RASS Assessment	
1. Observe patient: Patient is alert, restless, or agitated.	Score 0 to+4
2. If not alert, state patient's name and say to open eyes and look at speaker	
- Patient awakens with sustained eye opening and eye contact.	Score -1
- Patient awakens with eye opening and eye contact, but not sustained.	Score -2
- Patient has any movement in response to voice but no eye contact.	Score -3
3. When no response to verbal stimulation, physically stimulate patient by shaking shoulder and/or rubbing sternum.	
- Patient has any movement to physical stimulation.	Score -4
- Patient has no response to any stimulation.	Score -5

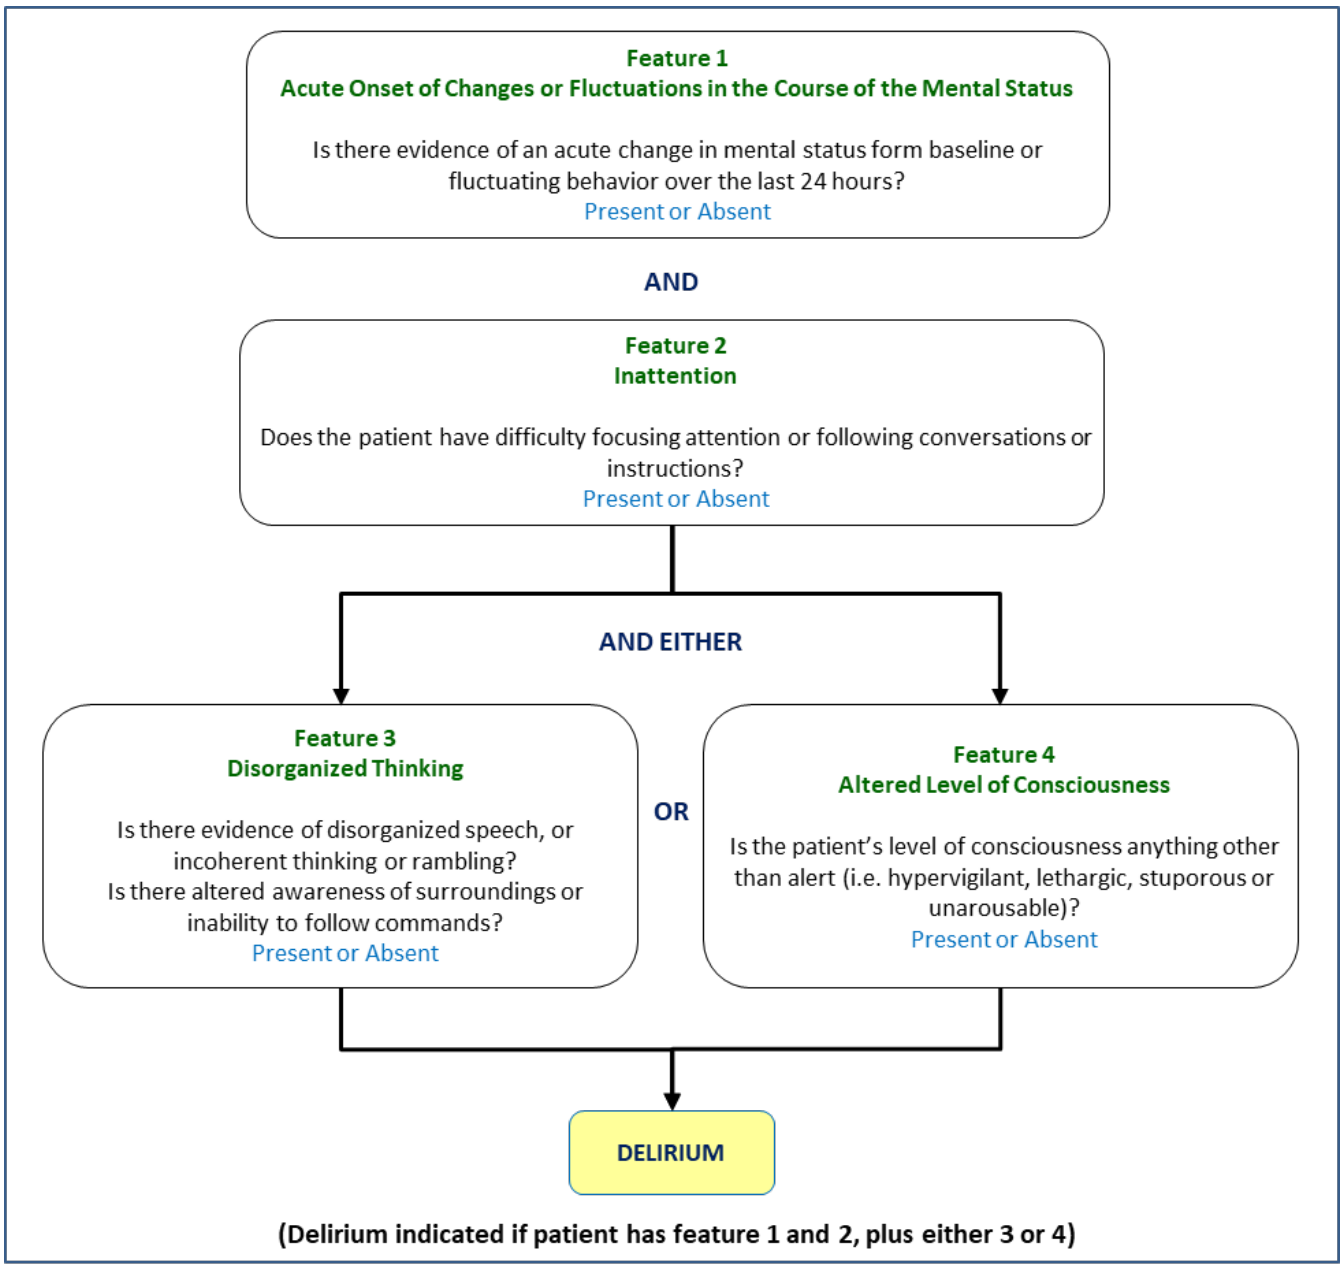
*Ely EW, Truman B, Shintani A., Thomason JWW, Wheeler AP, Gordon S et al. Monitoring sedation status over time in ICU patients: the reliability and validity of the Richmond Agitation Sedation Scale (RASS). JAMA 2003; 289:2983-2991.

APPENDIX E: THE CONFUSION ASSESSMENT METHOD



Feature 1
Acute Onset of Changes or Fluctuations in the Course of the Mental Status
Is there evidence of an acute change in mental status form baseline or fluctuating behavior over the last 24 hours?
Present or Absent
AND
Feature 2
Inattention
Does the patient have difficulty focusing attention or following conversations or instructions?
Present or Absent
AND EITHER
Feature 3
Disorganized Thinking
Is there evidence of disorganized speech, or incoherent thinking or rambling?
Is there altered awareness of surroundings or inability to follow commands?
Present or Absent
OR
Feature 4
Altered Level of Consciousness
Is the patient's level of consciousness anything other than alert (i.e. hypervigilant, lethargic, stuporous or unarousable)?
Present or Absent
DELIRIUM
(Delirium indicated if patient has feature 1 and 2, plus either 3 or 4)

APPENDIX F: BATTLEFIELD ACUPUNCTURE (BFA)

BFA requires appropriate training through the Acupuncture and Integrative Medicine Center at Joint Base Andrews or other approved training organization. An exception would be physicians without formal training but the requisite skills that easily translate to this procedure (i.e. surgeons, anesthesia, ER, critical care).

Supplies Needed: 10 Auricular Semi-Permanent (ASP) needles and alcohol pads.

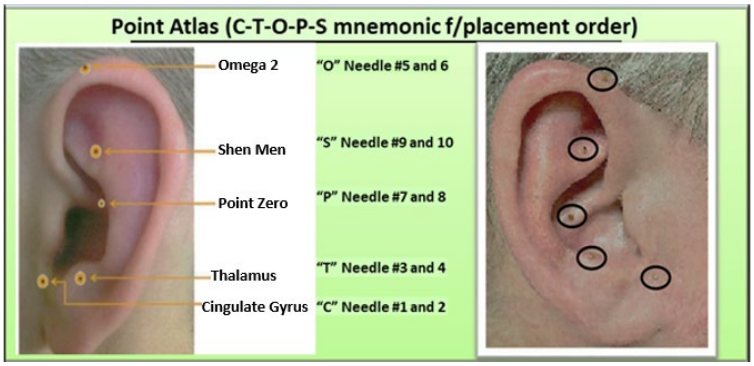
Patients should NOT receive BFA if:

- The patient has an active infection in an ear that is going to be used for BFA (treat only uninfected ear)
- A bleeding disorder is present (relative contraindication)
- The patient is pregnant or might be pregnant
- Current or previous keloid scar formation on either ear

Steps to apply BFA needles:

Read ALL steps before proceeding.

1. **Patient Education and Consent –** explain the procedure and expected course of having the ASP needle in place for 2-4 days while continuing regular activities.
2. **Cleanse area** – use alcohol swabs to disinfect both ears.
3. **Place ASP needles**
   a. Begin by applying needle at lowest point shown in figure below (the Cingulate Gyrus). Start on the side with most pain, then switch to the opposite side after body movements described in step b. Proceed to the next point and continue alternating sides until pain is resolved (0 or 1 out of 10).
   b. After each needle application, the patient should walk 10-20 steps unassisted or move their arms/legs for 30-60 seconds if physically unable to walk unassisted.
   c. If adverse symptoms are noted during the procedure, the last needle placed should be removed unless doing so is too uncomfortable. Symptoms include lightheadedness, near-fainting, euphoria, or increasing pain level.



4. **Post-care**
   a. Recommend patients keep brief written notes of their response to treatment.
   b. There is a small possibility of drowsiness, lightheadedness, and/or euphoria occurring up to 30 minutes after treatment.
   c. If effective, additional BFA treatments may be repeated every (5-7 days).

For more information, refer to the BFA Handbook on Deployed Medicine.

APPENDIX G: REGIONAL ANESTHETIC USE

Consensus Statement of American Society of Regional Anesthesia (ASRA) on LMWH as it relates to regional anesthetic use, adapted for use in combat casualties.

1. Antiplatelet or oral anticoagulant medications administered in combination with LMWH increases the risk of spinal hematoma. ASRA recommends against concomitant administration of antiplatelet drugs, standard heparin, dextran or coumadin, regardless of LMWH dosing regimen.
2. Needle placement should be delayed at least 10 to 12 hours after patient has received LMWH thromboprophylaxis.
3. Needle placement should be delayed at least 24 hours in patients receiving therapeutic LMWH.
4. In patients receiving twice daily dosing of LMWH:
   - Indwelling catheters should be removed before initiation of twice daily dosing regimen.
   - LMWH should be delayed for 2 hours after catheter removal.
5. In patients receiving single daily dosing of LMWH.
   - Catheters can be maintained in place.
   - Catheter can be removed no sooner than 10 to 12 hours after last dose of LMWH.
   - Subsequent LMWH should be withheld for two hours after catheter removal.
6. NSAIDs (including aspirin) alone do not add a significant risk for development of spinal hematoma.
7. Neuraxial anesthetic techniques should be avoided in patients who are receiving NSAIDS and LMWH.
8. These same recommendations apply for patients undergoing deep plexus or peripheral blocks.

APPENDIX H: SEDATION ORDERS

Allergies:_____Weight:_____kg

Diagnosis:_____

Service:_____Attending:_____

SEDATION ANALGESIA DELIRUM

See ICU Sedation Analgesia Delirium Algorithm

Nursing Orders

- ☐ Daily sedation Hold
  1. Hold sedation/analgesia daily.
  2. Assess pt for SBT if on ventilator.
  3. Restart sedation/analgesia at intermittent dosing;
  OR if patient's condition requires continuous infusion, restart infusion at ½ pre-interruption dose.
- ☐ Sedate to RASS goal of minus 2 to minus 1. See RASS scale. (Appendix D)
- ☐ ICU Sedation Analgesia Delirium Protocol.
  See CAM scale. (Appendix E)
  See Treatment Algorithm
- ☐ Notify MD
  For delirium prior to initiating pharmacologic treatment
  For patient on Clonidine - If SBP falls > 30 mmHg or DBP fall > 20 mmHg

ANALGESIA

Intermittent Dosing Start with Intermittent Dosing. If required more than Q 2 Hours, go to Continuous Infusion.

- ☐ fentanyl IV _____ mcg (25-100 mcg). Intravenous, EVERY 1 HOUR AS NEEDED for mild to moderate pain.
  Titrate pain medications to achieve a level 3 or _____ (pain scale 1-10).
  Start with Intermittent Dosing. If required more than Q 2 hours, go to Continuous infusion.
  Administer via slow IV.
- ☐ ketamine IV____mg (0.1-0.5 mg/kg). Intravenous, EVERY 1 HOUR AS NEEDED for mild to moderate pain.

Continuous Dosing Stop intermittent dosing if continuous infusion initiated and notify Pharmacy.

- ☐ fentanyl IV _____ mcg (25-250 mcg/hr), Intravenous, CONTINUOUS
  Titrate pain medication to achieve a level 3 or ____ (pain scale 0-10).
  Stop intermittent dosing if continuous infusion initiated and notify Pharmacy Services. **High-Risk Medication**
- ☐ fentanyl IV bolus _____mcg (25-100 mcg), Intravenous, EVERY 10 MINUTES AS NEEDED for breakthrough pain.
  Titrate pain medication to achieve a level 3 or ____ (pain scale 0-10).
  Administer via slow IV.
- ☐ ketamine IV _____mg (10-40 mg/ hr for ≥70 kg and < 60 years old) CONTINUOUS
  Titrate pain medication to achieve a level 3 or ____ (pain scale 0-10).
  Stop intermittent dosing if continuous infusion initiated and notify Pharmacy Services.
- ☐ ketamine IV_____mg (100 mcg/ kg/ hour) of ketamine CONTINUOUS
  Titrate pain medication to achieve a level 3 or ____ (pain scale 0-10).
  Stop intermittent dosing if continuous infusion initiated and notify Pharmacy Services.
- ☐ ketamine IV bolus 0.1-0.5 mg/kg , Intravenous, EVERY 10 MINUTES AS NEEDED for breakthrough pain.
  Titrate pain medication to achieve a level 3 or _____ (pain scale 0-10).

SEDATION: See RASS scale.

Intermittent Dosing Start with Intermittent Dosing. If required more than Q 2 hours, go to Continuous Infusion.

- ☐ lorazepam (aka ATIVAN) IV _____ mg (1-4 mg), Intravenous, EVERY 1 HOUR AS NEEDED for anxiety/agitation.
  Start with Intermittent Dosing. If required more than Q 2 hours, go to Continuous Infusion.
  Titrate sedation to RASS score of -1 to 0.

Continuous Infusion Stop intermittent dosing if continuous infusion initiated and notify Pharmacy.

- ☐ lorazepam (aka ATIVAN) IV infusion _____mg/hr (1-5 mg/hr), Intravenous, CONTINUOUS
  Stop intermittent dosing if continuous infusion initiated and notify Pharmacy.

Titrate sedation to RASS score of -1 to 0

☐ lorazepam (aka ATIVAN) IV bolus _____ mg (1-2 mg), Intravenous, EVERY 20 MINUTES AS NEEDED for breakthrough agitation/anxiety.
Titrate sedation to RASS score of -1 to 0

☐ midazolam (aka VERSED) IV infusion (avoid in renal/liver dysfunction) _____ mg/hr (1-6 mg/hr), Intravenous, CONTINUOUS.
Stop intermittent dosing if continuous infusion initiated and notify Pharmacy.
Titrate sedation to RASS score of -1 to 0

DEXMEDETOMIDINE: Continuous Infusion

☐ dexmedetomidine IV _____mcg/kg/hr (0.3-0.7 mcg/kg/hr), Intravenous, CONTINUOUS for 24 hours
1. Is rapid extubation expected (24-48 hrs)? Yes ☐ No ☐
2. Ordered by IC fellow or ICU staff? _____
3. Please select the indication (must meet one of the following):
   - ☐ Awake intubation ☐ BIPAP use requiring sedation
   - ☐ Bridge to extubation ☐ Desired light to moderate sedation

- Titrate in increments of 0.1 mcg/kg/hr Q 10 minutes to achieve a sedation score of 2-3 and pain score < 4/10.
- Do not exceed maximum dose of 0.7 mcg/kg/hr.
- Keep heart rate greater than ____ beats per minute and systolic blood pressure greater than ____ mmHg and mean arterial pressure greater than _____mmHg.
- Discontinue for heart rate < 45 beats per minute or if patient develops 2nd or 3rd degree Atrioventricular block.
- For persistent hypotension unresponsive to fluid challenge, decrease the rate by 50%.
- Discontinue if systolic blood pressure and mean arterial pressure do not return to parameters specified above in 10 minutes. Call physician for further instructions.

DELIRIUM: See CAM scale

Initiating Therapy

☐ haloperidol (aka HALDOL) IV x 1 _____mg (2-10 mg), Intravenous, ONCE For 1 Dose Administer over 1 minute. See CAM scale.

☐ haloperidol (aka HALDOL) IV PRN _____mg (2-5 mg), Intravenous, EVERY 15 MINUTES AS NEEDED for agitation.
Recommend not to exceed 20 mg over one hour.
Slow administration over 5-10 minutes preferred to minimize hypotension. See CAM scale.

Maintenance Dosing QTc monitoring required for patients receiving more than 10 mg haloperidol per day

☐ haloperidol (aka HALDOL) IV _____ mg (2-5 mg), Intravenous, EVERY 1 HOUR AS NEEDED for delirium.
Not to exceed dose 80 mg IV in 24 hours.
Slow administration over 5-10 minutes preferred to minimize hypotension. See CAM scale.

☐ quetiapine (aka SEROQUEL) PO tablet (Day 1) 25 mg, Oral, TWICE DAILY. See CAM scale.

☐ quetiapine (aka SEROQUEL) PFT tablet (Day 1) 25 mg, Feeding tube, TWICE DAILY. See CAM scale.

☐ quetiapine (aka SEROQUEL) PO tablet (Day 2) 50 mg, Oral TWO TIMES DAILY.
If patient responds to initial dose and PO/PFT available. See CAM Scale.

☐ quetiapine (aka SEROQUEL) PFT tablet (Day 2) 50 mg Feeding tube, TWO TIMES DAILY.
If patient responds to initial dose and PO/PFT available. See CAM scale.

☐ clonidine (aka CATAPRES) tablet PRN 0.1-0.2 mg, Oral EVERY 1 HOUR AS NEEDED for hypertension due to agitation.
- May repeat x 3 doses as needed, until SBP ≤ 140 mmHg (160 mmHg if over 65 years of age).
- If blood pressure goal is not achieved with clonidine 0.1 mg, give clonidine 0.2 mg every 1 hour as needed to achieve SBP ≤ 140 mmHg (160 mmHg if over 65 years of age).
- Once BP goal is met, move to maintenance and/or PRN dose.
- Hold clonidine if systolic blood pressure falls more than 30 mmHg of diastolic blood pressure falls more than 20 mmHg and notify physician.

☐ clonidine (aka CATAPRES) tablet scheduled 0.1-0.2 mg, Oral, EVERY 8 HOURS
Administer until SBP < 140 mmHg then change to maintenance/PRN dose.
Hold clonidine if systolic blood pressure falls more than 30 mmHg or diastolic blood pressure falls more than 20 mmHg and notify physician.

APPENDIX I: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires DoD health care practitioners consider it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Pelvic Fracture Care (CPG ID: 34)

Provides a brief review for the stabilization and treatment of pelvic fractures sustained in combat casualties.

Appendix B: Additional Information Regarding Off-label Uses in CPGs 7

Updated with aeromedical evacuation considerations, 26 Feb 2020.

BACKGROUND

Historically, injuries to the bony pelvis were relatively uncommon in the combat environment. The prevalence of Improvised Explosive Device (IED) attacks seen in the Iraq and Afghanistan operations against technologically improved tactical vehicles, as well as during dismounted operations, has led to an increased incidence of blunt trauma pelvic injuries.[1] The patterns of pelvic fracture in the combat environment tend to be more complex, more difficult to classify, and more commonly open than those seen in civilian trauma.

Hemodynamically compromised patients with pelvic fractures present a complex challenge to the trauma team as sharp spikes of bone resulting from pelvic ring injuries can lacerate surrounding soft tissues and induce brisk bleeding. The most common sources of bleeding are from fracture surfaces and the retroperitoneal venous plexus, with gluteal artery injuries occurring less commonly.[2, 3] Also at risk are the hollow visceral contents of the abdomen and pelvis, L5 nerve root, and lumbar plexus.

Pelvic fractures often occur in conjunction with other life threatening injuries. Civilian mortality rates have ranged from 6-35% with higher mortality rates associated with open fractures.[4-8] Death within the first 24 hours of injury in these patients is most often a result of **acute blood loss and associated injuries**.[8]

Recent analysis of mortality with combat related pelvic fractures identified large vessel injury, head injury, and injury to solid abdominal organs as risk factors for mortality in the setting of combat related pelvic ring injuries.[9] **Open pelvic fractures** in the combat environment have become more common most likely secondary to the increased prevalence of blast mechanisms of injury, combined with better patient survivability - attributed to rapid transport to surgical stabilization, use of tourniquets, the use of enhanced body armor and more aggressive massive transfusion protocols. These open fractures are often associated with other severe injuries, including lower extremity amputations. Combat related pelvic ring injuries are commonly high-energy and unstable injuries, frequently requiring operative fixation.

EVALUATION AND TREATMENT

NOTE: *Refer to Appendix A.*

1. Key issues in management of pelvic fractures are to identify if the patient is hemodynamically stable and if the pelvic fracture is mechanically stable. If the patient is not hemodynamically stable, it is imperative to identify all site(s) of hemorrhage as pelvic fractures often occur in conjunction with other life threatening injuries. Appropriate **evaluation of the abdomen, chest, and other potential sites of injury and hemorrhage** cannot be overstressed. Additionally, a **thorough examination of the pelvis and perineum** is required to rule out associated injuries to the rectum and genitourinary/gynecologic systems. Pelvic fracture is a common component of Dismounted Complex Blast Injury.[10]

2. When pelvic fractures cause hemorrhage, the bleeding occurs from three major sources: arterial, venous, and cancellous bone. Over 70% of hemorrhage associated with blunt pelvic trauma causing pelvic fracture is venous in nature and may be controlled with maneuvers that reduce the pelvic volume and stabilize the pelvis.[11] The other nearly 30% is associated with an arterial source and often requires procedural interventions such as **surgical packing and/or embolization**.[12] **Pelvic packing** can be a valuable technique, particularly when the patient is in extremis, or when laparotomy is required for associated injuries.[13]

3. In the austere environment, if open pelvic fractures continue to bleed despite retroperitoneal packing, bilateral internal iliac artery ligation should be considered.[14] In these dire circumstances, temporary cross-clamping of the aorta may help **control life-threatening hemorrhage** prior to dissection and ligation of the internal iliac arteries.

4. For pelvic fractures, **initial stabilization** with whatever means are available (sheet, pelvic binders, bean or sand bags, or pelvic external fixation) must be promptly implemented. In the combat environment, when fracture stability is unclear and specialist expertise is not available to determine pelvic fracture stability, stabilization with a sheet or binder is recommended. When possible, taping the knees and ankles together can minimize additional external rotational movement, and help improve the pelvic reduction achieved with a sheet or binder. Pelvic binders are correctly placed by centering over the greater trochanter of the femur, applying an internal rotational force to each hemi-pelvis through the hip joints.

5. The establishment of **standardized clinical treatment algorithms** for patients with pelvic fractures has been shown to greatly increase the probability of rapid stabilization of trauma patients.[15-18] Appendix A shows an algorithm in unstable patients.

6. A **multidisciplinary approach with early trauma surgery and orthopedic surgery coordination** is critical. The focus of the evaluation and treatment is early identification of injury with early mechanical stabilization as necessary and determination of hemodynamic instability with aggressive resuscitation for hemorrhage. When available, angiographic exploration with early embolization by skilled interventionalist for the hemodynamically unstable patient with intrapelvic hemorrhage may be beneficial-preferably in the operating room.[19]

7. Given that this capability is rarely available outside of a Role 3 facility, the next most beneficial maneuver is **retroperitoneal packing via a suprapubic incision**.[20,21] The temptation to open a retroperitoneal pelvic hematoma (as a result of a pelvic fracture) from inside the abdomen should be resisted and attempted only as a last resort although this may be necessary due to other intra-abdominal or pelvic injuries. In the casualty who remains hemodynamically compromised in spite of these efforts bilateral iliac artery ligation should be considered.[14] However, these interventions should not delay the necessary acute surgical treatment for concomitant hemorrhagic injuries.

AEROMEDICAL EVACUATION CONSIDERATIONS

1. Ensure fracture stabilized prior to transport.

2. Patient should be hemodynamically stabilized, with no evidence of active bleeding prior to transport. Coordinate with Theater Validating Flight Surgeon for exceptions.

3. Vibration in flight will increase pain. Ensure adequate pain control by ordering additional breakthrough pain medications.

4. Consider DVT prophylaxis. See the JTS Prevention of Deep Venous Thrombosis– Inferior Vena Cava Filter CPG, 02 Aug 2016.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Patients diagnosed with pelvic fracture.

INTENT (EXPECTED OUTCOMES)

1. Patients in the population of interest with hemodynamic instability (SBP < 100 or HR >100) receive pelvic stabilization (binder or external fixation).

2. Pelvic fracture patients who remain hemodynamically unstable after 2 units of blood product transfusion undergo hemorrhage control procedure at the same level of care where diagnosed (exploratory laparotomy, preperitoneal packing, REBOA, and/or interventional angiography embolization).

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with hemodynamic instability (SBP < 100 or HR >100) who receive pelvic stabilization (binder or external fixation).

2. Number and percentage of patients with pelvic fracture who remain hemodynamically unstable after 2 units of blood product transfusion undergo hemorrhage control procedure at the same level of care where diagnosed (exploratory laparotomy, preperitoneal packing, REBOA, and/or interventional angiography embolization).

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Director and the JTS Performance Improvement Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

Hemodynamically unstable patient with pelvic fracture without other injury requiring laparotomy
1. Initiate aggressive hemorrhage resuscitation with fluid and blood products
2. Rule out thoracic source of hemorrhage (i.e. ATLS and chest x-ray)
3. Wrap pelvis with sheet or apply pelvic binder
Ultrasound abdomen
POS
NEG
Operating Room
Laparotomy, consider extraperitoneal
On table angiography if available
Sheet/binder, external fixation where/when applicable
Resuscitation for hemorrhage
Operating Room
DPL and/or exploratory laparotomy
Consider pelvic packing when appropriate
External fixation when applicable
On table angiography if available
Bilateral iliac artery ligation if hemorrhage continues
No
Hemodynamically stable?
Yes
ICU (CT if available) Plan for pelvic external fixation if applicable
ICU (CT if stable and available)

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Prehospital Blood Transfusion

The CPG provides a brief summary of the scientific literature for prehospital blood use and essential instructions on resuscitation procedures using blood products.

Rapid Update, Jun 2023: *Calcium administration changed to 1 gram calcium*

PURPOSE

This Clinical Practice Guideline (CPG) provides a brief summary of the scientific literature for prehospital blood use, with an emphasis on the en route care environment. Updates include the importance of calcium administration to counteract the deleterious effects of hypocalcemia, minimal to no use of crystalloid, and stresses the importance of involved and educated en route care medical directors alongside at a competent prehospital and en route care providers (See Table 1.) With the paradigm shift to use FDA-approved cold stored low titer group O whole blood (CS-LTOWB) along with the operational need for continued use of walking blood banks (WBB) and point of injury (POI) transfusion, there must be focused, deliberate training incorporating the different whole blood options. Appropriate supervision of autologous blood transfusion training is important for execution of this task in support of deployed combat operations as well as other operations in which traumatic injuries will occur. Command emphasis on the importance of this effort as well as appropriate logistical support are essential elements of a prehospital blood program as part of a prehospital/en route combat casualty care system.

Table 1. Five Levels of Clinical Competence

Five Levels of Clinical Competence		
Skill Level	**Description**	**Trauma-related Example**
Novice	The novice has no experience in the environment in which they are expected to perform.	Administrator or technician who has never worked in a trauma center.
Advanced Beginner	The advanced beginner demonstrates marginally acceptable performance and has enough experience to note recurrent meaningful situational components.	Medic that has had didactic trauma training but no clinical trauma experience.
Competent	Competence is achieved when one begins to see one's actions in terms of long-range goals or plans. This individual demonstrates efficiency, coordination, and confidence in his/her actions.	Board eligible/certified physician, newly trained nurse, but has only rotated as a learner at a trauma center.
Proficient	The proficient individual perceives situations holistically and possesses the experience to understand what to expect in a given situation.	Board eligible/certified physician or newly assigned nurse with limited but recent prior exposure to trauma, starting their career at a high volume and best quality Level I trauma center.
Expert	The expert has an intuitive and deep understanding of the total situation and is able to deliver complex medical care under highly stressful circumstances.	Trauma nurse coordinator, Board certified Emergency Physician or fellowship trained trauma surgeon/intensivist with years of experience at a high volume and best quality Level I trauma center.

INTRODUCTION

Early administration of blood products to the trauma patient in extremis is the standard in combat casualty care and becoming more common as part of a strategy of civilian prehospital critical care.[1-7] Although there is some dissent regarding the level of evidence for and benefits of prehospital blood transfusion in the civilian literature, much of the data informing that discussion precedes the use of whole blood and involves a patient population dissimilar from the military.[8,9] Civilian Emergency Medical Services systems internationally[10,11] and in Texas, North Carolina and several other states have initiated whole blood transfusions in the prehospital environment. At least one civilian tactical law enforcement team has initiated a Low-Titer O Fresh Whole Blood program.[12] The main military literature covering this topic is summarized in Table 2 below.

Table 2. Military literature on prehospital transfusion

Article	Setting	Inclusion	Findings	Comments
Shackelford SA, Del Junco DJ, Powell-Dunford N, et al. **Association of prehospital blood product transfusion during medical evacuation of combat casualties in Afghanistan with acute and 30-day survival.** JAMA. 2017;318(16):1581-91.	Mostly Military air ambulance evacuations	1) Traumatic limb amputation at or above the knee or elbow or 2) Shock defined as a systolic blood pressure of less than 90 mm Hg or a heart rate greater than 120 beats per minute.	Adjusted hazard ratio for mortality associated with prehospital transfusion was 0.26(95%CI, 0.08 to 0.84,P=.02) over 24 hours (3 deaths among 54 recipients vs 67 deaths among 332 matched nonrecipients) and 0.39(95%CI,0.16 to 0.92,P=.03) over 30 days(6 vs 76 deaths, respectively)

Mil Med. 2013;178(7):785-91.	Military air ambulance in Afghanistan	Traumatic injury (chest/abd and single or multiple amputations) with 1) systolic blood pressure (SBP) <90 mmHg 2) heart rate (HR) >120 bpm 3) Oxygen Saturation (SaO2) <90%.	Feasibility study showed: 15 patients given 19 units no adverse reactions and no instances of blood product temperature outside of the accepted range	
O'Reilly DJ, Morrison JJ, Jansen JO, et al. **Prehospital blood transfusion in the en route management of severe combat trauma: a matched cohort study**. J Trauma Acute Care Surg. 2014;77 (3 Suppl 2):S114-20.	Regional Command South in AFG by MERT	MERT Physician order based upon injury severity and blood product availability	Matched cohort study of 1,592 patients in Afghanistan transported by a prehospital intensivist team found mortality significantly lower in those patients who received prehospital blood transfusions than those who did not (8.2% vs 19.6%, p<0.001	Confounded by different rates of invasive procedures

Prehospital blood transfusions during an eight-month period in one system were reviewed and found to be logistically complex but practically possible with repetitive training.[13] In another investigation, 15 patients safely received a total of 19 units of blood products according to pre-established guidelines for blood product transfusion in U.S. Army Medical Evacuation (MEDEVAC) units in Afghanistan.[14] Inclusion criteria for initiation of prehospital blood transfusion were: traumatic injury with systolic blood pressure (SBP) <90 mmHg or heart rate

(HR) >120 bpm or Oxygen Saturation (SaO2) <90%. Following the fifth transfused unit, oxygen saturation was excluded as a transfusion trigger and multiple amputations (with at least one proximal amputation) were included as transfusion triggers. There were no adverse reactions and no instances of blood product temperature outside of the accepted range.

Advanced clinical care during patient transport has demonstrated improved outcomes.[15-17] A growing body of evidence suggests that early blood transfusion, both at point of injury and en route to a surgical capability improves survival in severely injured patients with acute blood loss. Rapid initiation of blood transfusion among wounded personnel in Afghanistan was evaluated among 502 patients.[18] Patients who had been transported via MEDEVAC; who had suffered a traumatic amputation at/above the knee/elbow; had SBP <90 mmHg or HR >120 bpm; and who had received blood products during transportation, or, shortly after arrival in the hospital, were compared to those who did not receive blood. Those who received blood were significantly less likely to die at 24 hours (adjusted hazard ratio for mortality 0.26 [95% CI 0.08-0.84, p=0.02]) as well as at 30 days (adjusted hazard ratio for mortality 0.39 [95% CI 0.16-0.92, p=0.03]). This study underscores the importance of early transfusion. The en route care providers must continue (or in some cases start) transfusion as soon as the casualty is in the aircraft. Blood products that have started transfusion at POI can be continued during MEDEVAC.

A matched cohort study of 1,592 patients in Afghanistan transported by a en route care intensivist team found mortality to be significantly lower in those patients who received prehospital blood transfusions than those who did not (8.2% vs 19.6%, p<0.001).[19] Several confounding variables make these data difficult to interpret (e.g., differing rates of prehospital rapid sequence induction, administration of pharmacologic adjuncts and varied transportation times). Nevertheless, it is likely that an aggressive approach to prehospital critical care including blood transfusion was part of an overall strategy of damage control resuscitation that improved survival in severely injured patients.

PREHOSPITAL PRINCIPLES OF RESUSCITATION AND TRANSFUSION

- Rapid recognition of life-threatening hemorrhagic shock
  - Point of care devices if available: international normalized ratio; lactate level may be of value.
- Prevent hypothermia
- Hemorrhage control with mechanical hemostatic adjuncts:
  - Tourniquet/junctional tourniquet
  - Pressure dressings/thrombin and fibrin impregnated gauze
- Hemostatic Resuscitation
  - Whole blood (WB) is optimal
    1. FDA approved CS-LTOWB
    2. Low titer group O whole blood (LTOWB)
    3. Type O-WB (non-titered)
    4. Component therapy with plasma (dried, liquid, or, thawed), red blood cells (RBCs), and platelets in 1:1:1 ratio
- Avoid hypocalcemia/Calcium replacement

  - In prolonged evacuations, empiric calcium administration for every 4-6 units of RBCs or WB
- Avoid crystalloid resuscitation
- Tranexamic Acid administration if less than 3 hours from time of injury
- Consider source of freeze-dried plasma if available

***NOTE**: Conventional goal is systolic blood pressure >90mmhg. Recent concept indicates a higher goal of 90-110mmHg due to shift towards blood-based resuscitation and concern for prolonged hypoperfusion especially for patients with long transport times.*

CRITERIA FOR TRANSFUSION

Prehospital blood transfusion is predicated upon clearly defined criteria for the use of this valuable resource. Several high performing military and civilian prehospital medical teams use prehospital blood transfusion according to protocolized guidelines. The U.S. Army Ranger Regiment was an early adopter of prehospital blood transfusion and uses the following criteria for transfusion: signs and symptoms of hemorrhagic shock; OR 1+ amputation; blunt/penetrating trauma (junctional/abdominal/thoracic); OR pelvic fracture; OR SBP <100; OR lactate >5; pulse >100.[20] In Australia, the Greater Sydney Area Helicopter Emergency Medical Services (GSA-HEMS) is an intensivist-based prehospital critical care service that has extensive experience in prehospital blood transfusion. In the prehospital environment, they transfuse blood if there is "persistent hemorrhagic shock despite hemorrhage control measures after crystalloid infusion."[21] During interhospital transport GSA-HEMS transfuses blood if there is "persistent hemorrhagic shock where there is limited or no access to cross-matched blood and [an] ongoing requirement for transfusion." The Australian Queensland Ambulance Service Trauma Response Team administers blood products in the prehospital environment and a retrospective review of cases was published in 2014 demonstrating benefit in appropriate clinical situations.[22] In 2014, proposed criteria for prehospital blood products in combat casualties were refined based on data from Afghanistan[23] and updated in 2020 using a larger data set from the entire DoD Trauma Registry (DoDTR).[24] A case series reviewing the benefits of early whole blood administration in combat casualties was published in 2016.[25]

Development of transfusion criteria is an important consideration in establishment of a prehospital transfusion program. In the civilian trauma center experience, 596 trauma patients were evaluated using an assessment of blood consumption (ABC) score.[26] Patients received one point for any of the following: penetrating mechanism; positive focused assessment sonography for trauma (FAST); systolic blood pressure less than 90 mmHg; heart rate greater than or equal to 120 beats per minute. An ABC score of two or greater predicted the need for massive blood transfusion with 75% sensitivity and 86% specificity. This investigation demonstrated the utility of a quick, non-laboratory based tool to predict the need for blood transfusion.

Careful attention to transfusion triggers can limit wastage of this important resource in a potentially resource constrained environment. Furthermore, it is important to note that blood product usage can be optimized when hemorrhage control is undertaken simultaneously.[5,7] Ensure that hemorrhage control efforts are properly employed in accordance with Tactical Combat Casualty Care Guidelines. When administering blood, be certain to alert the receiving facility that the patient is requiring blood transfusion, noting any potential need for massive transfusion.

PROCEDURE

Certain special considerations for blood transfusion have been enacted in other Department of Defense transfusion algorithms.[27] Rapid transfusion of blood can cause sheering of RBCs and should be avoided if possible. When possible, low titer group O whole blood (LTOWB) should be administered as the blood product of choice. LTOWB has been screened for Anti-A and Anti-B antibodies. The titer of these antibodies is low enough to represent minimal risk of clinical consequences and may be considered a universal donor. LTOWB will be exclusively drawn from sites approved by the Armed Services Blood Program (ASBP), distributed in theater via the ASBP blood distribution system and fully tested in accordance with FDA guidelines.

Blood products should be transfused in a plasma:platelet:RBC ratio of 1:1:1. If platelets are not available, then plasma:RBC should be transfused in a 1:1 ratio. If that is not possible, then reconstituted dried plasma, liquid plasma or thawed plasma alone or RBCs alone should be transfused.

If available, type O negative RBCs should be used preferentially for females of childbearing years. If it is necessary to administer O positive blood to a woman of childbearing years with O negative blood, then consider Rhogam therapy to decrease the risk to subsequent pregnancies. Please note though that resuscitation and prevention of exsanguination takes precedence of potential future pregnancy complications. Pediatric blood transfusion should be based on clinical signs of shock rather than predefined vital signs, since vital signs can vary considerably between age groups in pediatric patients.

Blood plasma contains important clotting factors and can be transfused rapidly. Thawed plasma has a shelf life of 5 days and may not be available for prehospital missions. “Never frozen” liquid plasma has a shelf life of 26 days and may be more readily available. Check with the issuing facility for availability of thawed or liquid (i.e. never frozen) plasma. All blood products must be transfused immediately after removal from the storage container. If transfusion is delayed, then blood products that have been removed from storage and exceeded proper temperature will be returned to the issuing facility per local policy. Ensure that all blood products issues have a Safe-T-VUE (NSN 6515-08-T00-3056) attached and activated for temperature monitoring.
(See Appendix E).

QUALITY CONTROL

Proper storage, transport and administration of blood and blood products is addressed the following Joint Trauma System CPGs: Damage Control Resuscitation,[28] Frozen and Deglycerolized Red Blood Cells[29] and Whole Blood Transfusions.[30]

Ensure that the blood product container (NSN 6530-01-505-530I; OCP/5306; Desert) is properly charged and maintained prior to loading blood products. Ensure that all blood products have a Safe-T-VUE attached and activated for temperature monitoring. Ensure that thawed plasma is at a refrigerated temperature (1-6 degrees C) prior to placement of Safe-T-VUE. Appropriately document issuance and use of blood products per local protocol, including documentation in Theater Medical Data Store (TMDS) inventory.

Blood products carried outside of a medical treatment facility (MTF) and/or laboratory will be contained in an approved storage container for a maximum of 48 hours. Once loaded and sealed, a container will remain closed and intact until used for patient care or returned to the issuing facility. Units will inspect blood product containers and document appropriate quality metrics (e.g., intact, no leaking) every 24 hours.

TRANSFUSION REACTION

The rate of non-infectious transfusion reaction is low.[31] In a recent evaluation of 4,857 transfusion episodes approximately 1% were associated with a serious reaction.[32] Transfusion-associated circulatory overload was most common (~1%); while transfusion-related acute lung injury, anaphylactic reaction and hypotensive reactions all occurred in less than 0.1% of transfusions. Other investigators evaluated emergency transfusion of 5,203 units of type-O RBC to 480 trauma patients and found that no acute hemolytic transfusion reactions occurred.[33]

In the unlikely event of a prehospital transfusion reaction, immediately stop the transfusion. In cases of anaphylaxis, administer 0.3 mL of 1:1000 epinephrine intramuscularly (IM), administer diphenhydramine 25 mg IV or IM and consider methylprednisolone (the FDA approved dose of methylprednisolone is 10 – 40 mg IV over several minutes, with subsequent doses being determined by clinical response). Maintain the patient's airway as needed and administer IV fluids in cases of hypotension. In cases of acute hemolytic reaction, administer diphenhydramine 25 mg IV or IM, and consider osmotic diuresis with mannitol 20% 20 gm or 3% sodium chloride 250 mL.

HYPOCALCEMIA

Calcium administration should be considered in all patients undergoing en route care blood transfusion. The citrate preservative in blood products can chelate calcium and contribute to hypotension in patients who have received blood products.[34] In 352 patients who were critically bleeding and required massive transfusion, investigators found that hypocalcemia worsened mortality. Patients generally had low ionized calcium concentration (mean = 0.88mmol/L) and had higher odds of mortality (Odds Ratio = 1.25, 95% Confidence Interval 1.04-1.52; P = 0.02). Admission hypocalcemia is further associated with mortality.[35] Calcium concentration was measured in 591 trauma patients before administration of blood products. Those with an ionized calcium < 1 experienced higher mortality (15.5%) compared to those with ionized calcium levels >1 (mortality = 8.7%, p = 0.036).

Trauma patients are often hypocalcemic without regard to transfusion status, further suggesting that calcium administration may be beneficial.[36,37] In 212 trauma patients with a mean Injury Severity Score (ISS) of 34; 64% were found to be hypocalcemic (with calcium < 1.15 mmol/L) and 10% were severely hypocalcemic (<0.9mml/L). Hypocalcemia is common in massive transfusion and associated with increased mortality.[38,39] Although the mechanism of this effect is not completely understood, it is thought that acidemia related to tissue hypoperfusion may play a role.[40] Administration of one gram of calcium-IV/IO before, during (using a secondary access point) or immediately after the first unit of blood product. Re-dose one gram of calcium IV/IO after every 4 units of blood products.

TRAINING

Execution of prehospital and en route care blood transfusions requires sufficient training to adequately prepare. Conducting the most realistic training possible has been shown to improve in-hospital trauma team performance as well as the widely held belief of military training in general. Whole blood training should be viewed similarly.[41] Coordinated and deliberate autologous blood labs with appropriate oversight can safely achieve the highest degree of realism with relatively low cost.[42,43] Armed services blood bank policies for donor allowance in autologous blood lab participants is still under discussion.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All patients who receive blood product transfusion within 3 hours of injury
2. All patients who meet criteria for blood transfusion (severe traumatic injury: ISS ≥16 and ≥ 2 body regions injured with AIS severity ≥ 2 AND SBP < 100 OR HR > 100 OR hematocrit < 32% OR pH <7.25) within 3 hours of injury

INTENT (OUTCOME)

1. LTOWB is used for prehospital resuscitation of casualties with life-threatening injuries and hemodynamic instability (HR > 100 or SBP < 100).
2. For the population of interest, the first resuscitation fluid given after injury is a blood product, ideally cold-stored LTOWB.
3. Administration of whole blood and blood products to appropriate combat casualties in the prehospital and en route care environment.

PERFORMANCE/ADHERENCE METRICS

1. The number and percentage of patients in the population of interest who receive WB transfusion prior to arrival at first role of care.
2. Number and percentage of patients in population of interest who received a blood product as the first resuscitation fluid.
3. Number and percentage of patients in population of interest who received cold-stored LTOWB as the first resuscitation fluid.
4. Indication identified.
5. Pre and post vital signs measured.
6. Calcium administration documented.
7. Appropriate information collected for donor and recipient exposure monitoring.

DATA SOURCES

- Patient Record (DD1380/DA4700 OP7)
- DoDTR

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting frequency will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Improvement Branch.

RESPONSIBILITIES

It is the Unit Medical Director's responsibility to ensure familiarity, training, appropriate compliance and PI monitoring at the local level with this CPG. Coordination with the Regional Medical Director and Trauma Director is also essential in ensuring full spectrum compliance and PI monitoring along with clear communication with the Combatant Command Trauma System and Joint Trauma System.

APPENDIX A. PREHOSPITAL BLOOD TRANSFUSION PROCEDURES

BEFORE

Criteria for Blood Transfusion:

- HR >100 bpm; or
- SBP <100 mmHg or no radial pulse; or
- Altered mental status with signs/symptoms hemorrhagic shock; or
- Penetrating trauma to chest/abdomen, junctional injuries; or
- Pelvic fracture; or
- Any above knee amputation or multiple amputations (regardless of vital signs)

DURING

1. **Obtain IV/IO access**
   a. Verify blood product identification number
   b. Connect IV tubing with filter to blood
   c. Transfuse as rapidly as tolerated
2. **Monitor for signs of transfusion reaction:**
   Hypotension, flushed face, wheezing, fever, rigors, flank pain
   - Anaphylaxis = Epinephrine 0.3 mL of 1:1000 IM; Diphenhydramine 25 mg IV/IM; Maintain airway; Administer IV fluids prn; Consider Methylprednisolone
   - Acute hemolytic reaction = Diphenhydramine 25 mg IV/IM; Consider osmotic diuresis with 20 gm mannitol 20% or 250 mL 3% NaCl

AFTER

Resupply from pre-designated source: Consider 1 gram calcium IV

***Abbreviations**: Heart rate (HR), Beats per minute (bpm), Systolic blood pressure (SBP), Intravenous (IV), Intraosseous (IO), Intramuscular (IM), As needed (prn), Gram (gm), Sodium chloride (NaCl)*

APPENDIX B: RESUSCITATION USING BLOOD PRODUCTS DURING TACEVAC

Source: Vampire Program: CENTCOM Clinical Operations Protocol-01: Urgent Resuscitation using Blood Products during Tactical Evacuation from Point of Injury

PURPOSE

To provide essential instructions on urgent/life-saving resuscitation procedures using blood products during tactical evacuation (refers to both casualty evacuation and medical evacuation) from the point of injury (POI) for casualties suffering major blood loss/massive hemorrhage. Referred to as the *Vampire Program.* This guideline supports the Joint Trauma System (JTS) Damage Control Resuscitation Clinical Practice Guideline (CPG), Whole Blood Transfusion CPG, and the Tactical Combat Casualty Care (TCCC) Guidelines.

Guidance applies to medical and non-medical personnel (e.g., flight medic, crew chief, registered nurse, enlisted medical personnel, physician, nurse practitioner, or, physician assistant), assigned/attached or allocated to perform tactical medical response (TCCC) and evacuation (CASEVAC and MEDEVAC) duties that involve direct or indirect patient care.

FIELD INDICATIONS FOR TRANSFUSION DURING TACTICAL EVACUATION

The following are indications for transfusion in the presence of severe traumatic injury:

- Systolic BP <100 or absence of radial pulse; or
- Heart rate >100; or
- Any above knee amputation or double/triple/quadruple amputation (regardless of vital sign indication).

WARNING*: The amputation patterns above are the only traumatic injuries that constitute a stand-alone immediate field indicator for transfusion that requires no confirmation with vital sign parameters.*

CAUTION*: Control external bleeding before or simultaneously with initiation of blood product transfusion.*

Traumatic Arrest: patient with exsanguination who had signs of life when received from ground forces and has since become pulseless should receive immediate transfusion (transfusion is more important than chest compressions in cases of exsanguination and should take priority).

Traumatic injuries where early blood transfusions are most likely to be needed:

- Penetrating thoracic/abdominal/junctional (junctional includes axilla/inguinal/cervical) injury.
- Pelvic fracture.
- Multiple injuries.
- Proximal amputations (above knee or elbow). Amputation is defined as any severe trauma to a limb that involves complete or partial loss of the limb (this includes limbs that are severely mangled but not completely severed).

Initiate transfusion with 1 unit of blood product. Give additional units if clinically indicated. Avoid resuscitation with crystalloid which may increase bleeding, particularly from non-compressible torso hemorrhage.

Refer to Appendix C for list of clinical indicators for hemorrhagic shock.

PROCEDURE

Blood Component Therapy Approved for Transfusion during Tactical Evacuation

Red blood cells (RBCs) increase the recipient's oxygen-carrying capacity by increasing the mass of circulating red cells. Plasma and platelets work together to improve blood clot formation and clot stability. On average a unit of whole blood (WB) contains a volume of 500-600 mL and a unit of RBC's contains a volume of 300-400 mL. In an exsanguinating patient, a unit of blood can be given quickly. Ensure good blood flow through IV or IO access before initiating transfusion. Refer to Appendix D for Transfusion Procedures and Appendix F for Pearls for Transfusion.

***CAUTION**: Rapid infusion against resistance can cause mechanical shearing of RBCs and should be avoided.*

1. Blood products will be administered in the following priority depending on availability and according to TCCC Guidelines:
    a. Cold Stored Low titer Group O whole blood (LTOWB), or, if not available
    b. Fresh Low titer Group O whole blood (LTOWB), or, if not available
    c. Plasma, RBCs, and platelets in a 1:1:1 ratio, or, if not available
    d. Plasma and RBCs in 1:1 ratio, or, if not available
    e. Reconstituted dried plasma, liquid plasma, or, thawed plasma alone or RBCs alone, or, if not available
    f. Fresh group O (typed by Eldon card or equivalent) whole blood from unknown titer walking blood bank

    ***NOTE**: LTOWB has been screened for anti-A and anti-B antibodies; these units contained a low titer of anti-A and anti-B and are therefore considered a universal donor product that may be given to recipients of any blood type with a minimum risk for a minor ABO incompatibility (typically minor and most often subclinical clinical consequences). The whole blood supplied to MEDEVAC units will be exclusively drawn in the United States from the ASBP-approved sites and distributed in theater by the ASBP blood distribution system. The LTOWB units will be fully tested following FDA current guidelines.*

2. POS (either low titer Group O WB or Type O RBCs) is the standard for transfusion during evacuation.

> ***NOTE**: Patients requiring blood can safely receive un-cross matched low titer Group O WB or Type O RBCs until type-specific products are available.*

3. If available, use O NEG on females of childbearing potential age <50 years old. Inform receiving facility regarding female given O POS blood for documentation in the medical record. If a minimal amount (just a few milliliters) is given, consider Rhogam therapy. The immunologic consequences of administration of an entire unit of O POS whole blood or RBC to an O NEG female of child-bearing potential cannot safely be reversed with Rhogam. Treatment of exsanguination takes precedence over potential future pregnancy outcomes.

> ***CAUTION**: WB collected in theater will NOT be supplied for use onboard MEDEVAC aircraft.*

Plasma is recognized as an important component in preventing and treating coagulopathy in trauma. On average a unit contains a volume of 200-250 mL and is transfused rapidly.

1. Type A or AB thawed plasma is the current standard for transfusion during evacuation.
2. Thawed plasma only has a shelf life of 5 days and may not be available for the pre-hospital mission. Liquid plasma (never frozen) has a shelf life of 26 days. Check with issuing facility or blood supply unit for availability.

The recommended mission loads for tactical evacuation are based on operations tempo and determined by the theater or Joint Task Force surgeon. Specific missions may require additional blood products; units will refer to the Joint Blood Program Office.

1. Golden Hour Container (GHC) maximum capacity is 4 units RBC/FFP or 2 units of whole blood.
2. If whole blood or plasma is unavailable, evacuation personnel will fly with RBCs exclusively.
3. Product must finish infusion within 4 hours of spiking the bag. If not complete, then it needs to be stopped and the remainder of the product discarded. If the initiation of transfusion (spiking of the bag) is delayed, then the blood may be returned to storage if it hasn't exceeded appropriate transport temperature, which is a max of 10C. The only way this can be determined is with use of a Safe-T-Vue sticker on the actual blood bag.
4. Unused blood products (i.e. WB and freeze dried plasma [FDP]) furnished by forward U.S. or Coalition Forces will not be used by evacuation personnel. Recommend products be left with forward forces. Blood products (WB and FDP) spiked by forward forces and transfusing at time of pick up will be continued during evacuation.

Pediatric patients:

1. Emergency transfusion of pediatric patients relies on clinical assessment rather than specific vital signs, since normal heart rate and blood pressure are age-dependent.
2. Clinical signs of shock are the same as in adults (cool, pale, weak or absent radial pulse, delayed capillary refill, decreased mental status).
3. Pediatric fluid resuscitation related to trauma begins with 10 mL/kg of first blood product, then repeat as needed based on response.

Receiving Blood Components from an Issuing Facility (U.S. and Coalition)

U.S. issuing facility personnel from the Blood Support Detachment (BSD), MTF (Role 2/3) or lab will:

1. If requested and available, thaw frozen plasma IAW local procedures and label products (A or AB) with 5 day expiration date.
2. Ensure GHC is properly charged and removed from freezer 25-30 minutes prior to loading blood products.
3. Ensure all blood products issued have a Safe-T-VUE (NSN 6515-08-T00-3056) attached and activated for temperature monitoring (Appendix E). ***Ensure thawed plasma is at refrigerated temperature (1-6°C) before placing Safe-T-VUE on unit.***
4. Evacuation personnel will follow Safe-T-VUE procedures (Appendix E) when required.
5. Document in TMDS the issuance of blood products to an evacuation team (e.g., DUSTOFF; Pararescue; Tactical Critical Care Evacuation Team).
6. Complete appropriate sections of the SF 518 *Blood or Blood Component Transfusion Record* for issuing blood products; place inside GHC pocket or attach form to each unit of blood product issued.
7. Verify the blood information on the SF 518 against the blood product label with receiving evacuation unit personnel.

Non-U.S. Issuing Facility: When U.S. blood products are to be issued from a Coalition facility, contact the Joint Blood Program Office to coordinate issuing requirements and documentation of units received.

Receiving unit (Evacuation Unit) personnel will:

1. Prior to sealing GHC, ensure each blood product loaded into the GHC has an activated Safe-T-VUE attached (Appendix E) and an SF 518 Form.
2. Accept blood products into receiving unit's TMDS inventory.
   If receiving unit is unable to access TMDS, the issuing facility will access account and receive the products under the receiving unit's TMDS inventory.

Storage, Transportation and Monitoring of Blood Products

1. All blood and blood components must be maintained in a controlled environment and stored under appropriate conditions.
2. Blood products carried outside a BSD/MTF/Lab will only be transported in an approved storage container (e.g., Golden Hour Container NSN 6530-01-505-5301; OCP/5306; Desert) for a maximum of 48 hours.
3. Units will monitor containers and document status (e.g., dry/no leaking noted) at a minimum of every 24 hours.
4. Once loaded and sealed, container will remain closed and intact at all times until blood product is required for patient care.

5. Notify the issuing facility (BSD/MTF/Lab) as soon as possible when blood products have been used.

6. GHC is only approved for 48 hours use; prior to expiration end users will contact issuing facility (BSD/MTF/LAB) to coordinate the return and exchange of a container and blood products per mission requirements.

***WARNINGS**:*
- At no time will container or its contents (blood products) be placed in a refrigerator or other cooling device outside a blood bank.
- Blood products will not be used if container is leaking; or the temperature indicator (Safe-T-VUE) on the blood product is out of standard (refer to Appendix E).
- Notify the issuing facility and return container and products for replacement.

Individual and Unit Training Requirements

1. At a minimum, medical personnel who participate in the administration of blood products during evacuation will be trained in the following topics:

    a. Indications for transfusion (Appendix C)

    b. Transfusion procedures (Appendix D);

    c. Documentation (Appendix G)

    d. PEARLS for transfusion (Appendix F)

    e. Submission of a patient safety report when required

2. At a minimum, non-medical personnel who assist will be trained in the following:

    a. Transfusion procedures

    b. Equipment/supplies

    c. Documentation requirements for the SF 518

3. Units who implement this CPG will train appropriate personnel on the following:

    a. Emergency procedures for in-flight complications.

    b. Storage container/blood product exchange requirements.

Essential Items Required for Implementing a Vampire Program

1. Approved blood component transport container.

    a. Recommend between 4 and 6 each GHCs for a Vampire Program (NSN 6530-01-505-5301 (OCP)/5306(Desert)).

b. Hemacool (NSN 4110-01-506-0895) or other freezer with temp check to ensure a temperature ≤ to (-) 18°C to support reconditioning of GHC.

2. Safe-T-VUE (NSN 6515-08-T00-3056) for temperature monitoring. (Refer to Appendix E.)

3. Establish Theater Medical Data Store (TMDS) accounts for an issuing facility (BSD/MTF (Role2/3) and LAB); and receiving unit (evacuation unit)

Warming Devices for Blood Transfusion

Use of infusion warming devices is highly recommended. These will be FDA approved for the actual use in transfusion of blood products (examples of devices include: Belmont® Buddy-lite™, EnFlow® or Thermal Angel).

***WARNING**: Warming devices will have safety mechanisms built in that prevents the output temperature from exceeding 42°C. Unit personnel will be familiar with safety mechanisms for the device used.*

Tranexamic Acid (TXA)

Patients receiving blood transfusion within three hours of injury should also receive TXA. Refer to the TCCC guidelines for administration of TXA.

Record Keeping and Documentation Requirements

1. Transfusions will be documented into TMDS by evacuation personnel, or, by issuing facility.

2. Personnel will refer to the Theater Blood Application Training Guide, 02 Jun 2014 for directions on Inventory Management-and for Transfused Products.

3. Complete SF 518 documentation and turn over at the destination MTF for placement in the patient's medical record.

References

APPENDIX C: CLINICAL INDICATIONS OF HEMORRHAGIC SHOCK

Clinical Evidence Hemorrhagic Shock Is Present		
H	Hypotension	Systolic blood pressure <100mmHg
T	Tachycardia	>100 BPM; Unresponsive to a 250-5000cc fluid bolus (NS/LR)
R	Respirations	Rapid/shallow
P	Pulse (poor character)	Weak and thready (ineffective)
M	Mental status	Decreased (excluding head injury)
S	Skin color	Pale/cyanotic
C	Continued bleeding	From non-compressible wound

APPENDIX D: TRANSFUSION PROCEDURES

TRANSFUSION PROCEDURES

MAINTAIN UNIVERSAL PRECAUTIONS (Gloves & Eye Protection)

STEP 1: ESSENTIAL BLOOD ADMINISTRATION ITEMS

1. "Y" Type Filtered Blood Administration Set (**UNDER NO** circumstances should non-filtered tubing be used)
2. Blood Product to Transfuse (**Universal Donor is approved for Prehospital**)
3. 0.9% NS (**Dedicated Line Only for Blood Products**)
4. Blood Pressure Cuff/Monitor
5. Blood Warmer Device
6. Pressure bag (if available)

STEP 2: PRE-TRANSFUSION TASK

Two Person Verification Process

Verify Blood Label. Complete SF 518 for 5 items below or transcribe items from Blood Label onto blank SF 518: (1) Unit#; (2) Type of Product; (3) Donor ABO/Rh (**Must be O for RBCs; and A or AB for Plasma**); (4) Expiration Date; and (5) Temperature Indicator (RED = NOT ACCEPTABLE)

1. CLOSE all 3 clamps on Y tubing
2. NOTE: When using blood/fluid warming device, attach line to fluid warmer cartridge and fluid warmer extension line.
   a. Ensure warming device is functioning IAW manufacturers guidelines
3. Insert 1st spike into NS bag and hang; OPEN clamp and prime only the "Y" section; CLOSE clamp
4. Insert 2nd spike into blood product and hang; OPEN clamp and run the length of the tubing
5. Attach line to IV or IO site ****Ensure good flow through IV/ IO before initiating transfusion****
6. Ensure all clamps are CLOSED
7. Note/document pre-transfusion vitals - at a minimum BP and HR
8. **Medical person will visually inspect blood product, if possible, for gas, discoloration, clots, foreign objects, or, sediment, and ensure no cracking of the plastic bag that has led to leaking.**
   a. **Visually inspect the Temperature Indicator** (RED = NOT ACCEPTABLE)
9. Non-Medical person can assist with documentation on the SF 518 for Pre and Post transfusion in formation

STEP 3: TRANSFUSION TASK

1. OPEN main line clamp for blood product to begin infusion.
   a. **ENSURE CLAMP to NS REMAINS CLOSED.**
   b. **UNDER NO CIRCUMSTANCES** will other medications or IV fluid (including 3%NS) be introduced through transfusion line. This will cause hemolysis/clotting of blood products.
2. **Blood products must be transfused within 4 hours of removal from a storage container** - if not, the product(s) will be returned to issuing facility or delivered with patient to MTF to be discarded.
3. If using pressure infuser set pressure to 300 mmHg.
4. Monitor vitals IAW TCCC Guidelines.
5. When blood product has been infused, CLAMP blood product line and OPEN NS line to deliver residual blood product.
6. If 2nd Unit required - CLOSE NS clamp.
7. Spike 2nd Unit - OPEN blood product and main line clamps to begin 2nd infusion.
8. Monitor closely and continue VS assessment.
9. VS goal: SBP >l00mmHg; and/or Pulse <100; MAP 70-80 mmHg

STEP 4: DOCUMENTATION TASK

1. **Pre-transfusion Data**
   a. Unit Number
   b. Type of Blood Product (RBC/ Plasma)
   c. Donor ABO/Rh
   d. Expiration Date
   e. Vital Signs (HR and B/P)
2. **Post Transfusion Data**
   a. Vital Signs
   b. Date/Time started/completed
   c. Note if interrupted and reason for interruption
   d. Patient Identification (as much as possible)

APPENDIX E: SAFE-T-VUE TEMPERATURE INDICATOR

SAFE-T-VUE TEMPERATURE INDICATOR

ISSUING FACILITY INSTRUCTIONS

1. Safe-T-VUE® 10 is a temperature sensitive indicator that easily adheres directly to blood bags during transport and changes color from WHITE to RED when the 10°C indication temperature has been reached or exceeded.
   a. Safe-T-VUE is non-reversible and indicates that a high temperature condition existed, even if temperature returns to a lower level. As long as indicator remains WHITE, blood may be stored for future use.
2. Prepare the Safe-T-VUE temperature indicator by refrigerating for a minimum of 24 hours at 1-6°C.
3. Remove the blood product and one Safe-T-VUE indicator from the refrigerator at the same time and place on a clean dry surface.

NOTE: Remove excess moisture from the blood product bag by using a dry wipe/paper towel on the surface where the Safe-T-VUE is to be applied.

NOTE: Use of cold pack on the surface below the blood product will help to maintain temperature

4. Hold Safe-T-VUE against the blood product with fingertips. Peel off the "REMOVE" label to expose the adhesive.

NOTE: Be careful to only handle around the edge of the indicator to expose RED DOT and WHITE DOT.

5. Attach Safe-T-VUE directly to the lower third of the blood product bag where there is a large volume of product.

CAUTION: Ensure thawed plasma is at refrigerated temperature (1-6°C) before placing Safe-T-VUE on unit.

NOTE: Be certain the Safe-T-VUE indicator is in complete contact with the blood component bag being monitored. No air pockets should be under the indicator (e.g., fold in the bag; over any labels; or any other obstruction).

6. Fold WHITE DOT onto the RED DOT and press firmly together to activate.

CAUTION: Be careful to ONLY press on the GREEN color-coded end to activate properly.

CAUTION: It is important to place pressure on the outer edge of the WHITE DOT, and not the center, when pressing onto the RED DOT to prevent false activation.

7. Issuing facility will complete documentation on SF 518 for each blood product unit, place inside GHC pocket and secure container.
8. Receiving personnel will understand color change temperature indication:
   a. When WHITE DOT turns solid RED, temperature has reached ≥10°C
      - Return blood product to issuing facility (BSD/MTF/LAB)
   b. Appearance of SMALL RED DOTS is an indication blood product requires cooling or immediate refrigeration.
      - Return product to issuing facility (BSD/MTF/LAB) for appropriate cooling/refrigeration
   c. WHITE DOT –product is acceptable for transfusion

APPENDIX F: PEARLS FOR TRANSFUSIONS

PEARLS FOR TRANSFUSIONS

PRE-TRANSFUSION PEARLS

1. Use of 2% Lidocaine (2-3ml) with 0.9% NS is permitted to flush any IO site prior to blood product transfusion.
2. Consider pain control measures to reduce tachycardia resulting from uncontrolled pain.
3. Once removed from storage container blood products will be transfused in under 4 hours
4. ONLY USE "Y" filtered blood administration sets
5. If directly involved in patient care, 1st Verifier (Medical Person) can direct a non-medical person to be the 2nd Verifier and record data on the SF518
6. **DO NOT** use blood product if storage container is leaking or temperature indicator is **RED**
7. **If using enFLow® fluid warmer – add IV extension tubing
8. DO NOT allow blood warmer to be placed directly on patient's skin as this may cause burning
9. If Thawed plasma is available, it should be given prior to RBC; normal ratio is 1:1

DURING TRANSFUSION PEARLS

1. Transfusion infusion rates can be titrated to slower rates if VS parameters move to appropriate levels (SBP>100; HR<100; MAP 70-80).
2. Special attention should be paid to non-compressible injuries (chest; abdominal; and pelvis) so as to NOT raise the SBP over 90mmHg.
3. Once transfusion is initiated, decrease all other fluids to KVO rate.
4. **In-flight emergencies:**
   a. Contact unit FS or tactical operation center for medical direction; or
   b. **Divert to nearest MTF (Do not delay divert waiting on medical direction)**
5. If transfusion is interrupted, record date/time and reason for interruption on SF518 if not able to resume within 5 min
6. Under **NO CIRCUMSTANCES** will other medications or IV fluids (to include 3% NS) be introduced through transfusion line.
7. Blood output temperature from a warmer device **WILL NOT EXCEED** 42°C (107°F)

DURING TRANSFUSION PEARLS

1. Suspected /confirmed transfusion reaction: STOP TRANSFUSION
2. **Disconnect tubing from infusion site; flush IV site with NS**
3. Keep IV Line OPEN with NS
4. Re-initiate transfusion only if it is deemed clinically essential
5. Document on SF 518 date/time and actions taken

POST TRANSFUSION PEARLS

1. After 1st transfusion, re-evaluate casualty and initiate 2nd unit ONLY if criteria is still met (Appendix A)
2. If 1st unit is initiated based on "Stand-Alone" injury (Double/Triple/Quadruple Amputation); subsequent units will be based on VS parameters
3. Complete documentation on SF518
4. Consider Tranexamic Acid (TXA) – follow TCCC Guidelines for Administration

PATIENT HAND-OFF (COMMUNICATION)

1. Provide receiving MTF with completed SF 518s for patients record
2. Report any adverse events; transfusion reactions ; and actions taken en route
3. Report interrupted transfusions and provide explanation
4. Report O POS blood given to female patients between the age of 10-50

APPENDIX G: REQUIRED DOCUMENTATION FOR TRANSFUSION

- SF 518 Blood or Blood Component Transfusion Record ASBP
- 151 Whole Blood Transfusion Checklist
- 147 Eldon Card ABO/Rh Typing Record
- 145 Infectious Disease Testing for Blood Donation
- 148 Pre-screen Whole Blood Sample Shipping Manifest
- 150A Emergency Release Letter of Understanding (tested)
- 150B Emergency Release Letter of Understanding (untested)
- 572 Emergency Whole Blood Donation Record
- AABB Medications Deferral List
- DHQ Medication Deferral List

APPENDIX H: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

The Prevention of Deep Venous Thrombosis – Inferior Vena Cava Filter (CPG ID: 36)

To establish guidance for 1) anti-thrombotic therapy for the prevention of deep venous thrombosis (DVT) and pulmonary embolism (PE) and 2) the management of inferior vena cava filters (IVCs) placed in the combat theater for the purpose of either primary or secondary prophylaxis of pulmonary embolism.

Appendix C: Additional Information Regarding Off-label Uses in CPGs 12

BACKGROUND

Trauma patients are known to be at high risk for Venous Thromboembolism (VTE) including Deep Venous Thrombosis (DVT) and Pulmonary Embolism (PE). Major trauma patients can have up to 58% incidence of DVT.[1] Sevitt and Gallagher reported an even higher incidence (65%) in injured and burned patients and reported a 16.5% incidence of PE found at autopsy in this cohort of patients.[2,3]

In addition to the hypercoagulable state induced by severe injury in trauma, combat casualties have additional risk factors for DVT, including:[1,4-8]

- Early transfusion of blood products (≤24 hours);
- Transfusion of old blood (≥28 days);
- Multiple and/or above the knee amputations

The use of Fresh Frozen Plasma (FFP) outside of large volume blood product transfusion (less than 4 U PRBC's) incurs an increased risk of VTE.[9] Early prophylaxis in this patient population is recommended provided hemostasis has been achieved.

The nature of the current combat theater has provided our deployed medical team's ample opportunity to care for children injured as non-combatants. The incidence of DVT after trauma is much lower (6.2%) than that of adults in the civilian literature.[10] The presence of multiple risk factors including immobility and central venous line, however, were associated with the development of DVT in pediatric trauma patients.

There is an increasing recognition of DVT in individuals who complete an extended period of travel on an airplane. One study noted a 10% prevalence of asymptomatic DVT in individuals undergoing flights of 8 hours or more.[11] Combat casualties are at high risk for VTE during recovery and evacuation, which can be associated with long flights and immobility, thus it is important to start VTE prophylaxis as soon as clinically possible.[12]

Landstuhl Regional Medical Center is uniquely positioned to receive patients who have undergone extensive periods of travel prior to admission.

Different medical societies and working groups have published varying recommendations for DVT prophylaxis.[13,14] The clinical guidance recommended here represent the guidelines with either a higher level of scientific evidence supporting the recommendation, or the more conservative recommendation. It is recommended to begin DVT prophylaxis therapy as soon as coagulopathy is corrected in patients not otherwise at increased risk of bleeding.

RECOMMENDATIONS FOR DVT PROPHYLAXIS

Unless contraindicated by lower extremity injury, all trauma patients should receive:

1. Sequential Compression Device (SCD) therapy as primary DVT prophylaxis in addition to;
2. Low dose Unfractionated Heparin (UFH)[13-15]; or
3. Low Molecular Weight Heparin (LMWH), Enoxaparin 30mg subcutaneous (SC) twice daily.[16]
4. Alternatively, low does LMWH such as Dalteparin 5000 U SC or Enoxaparin 40mg SC can be given daily and in one study has a lower incidence of DVT when compared to 30mg BID dosing in post-operative patients.[14,17,18]

5. Unfractionated Heparin (5000 U) administered subcutaneously three times daily has been demonstrated to be as effective as or at least non-inferior to Enoxaparin in the prevention of DVT in trauma patients.[19,20]

Consideration should be given to the use of LMWH in patients with impaired renal function (CrCL=30ml/min or less), as there is a concern for LMWH accumulation and increased risk of bleeding.

1. Despite this concern, no clear evidence exists for dose modification or contraindication to the use of LMWH for DVT prophylaxis in renal impaired patients.[21]

2. Godat et al. reported, however, that trauma patients who are considered to be at the highest risk to develop VTE (especially spinal cord injury with/without pelvic fracture) are at the greatest risk during the first three months after injury and that this risk decreases at six months post injury.[23]

The role of **duplex ultrasound** in the diagnosis of DVT should be reserved for the symptomatic patient. Serial screening duplex ultrasound for the diagnosis of DVT is not recommended.[14]

CHEMICAL DVT PROPHYLAXIS

Provided coagulopathy and ongoing bleeding is corrected, chemical DVT prophylaxis (<48 hours post injury) has been shown to be safe after blunt solid organ injuries.[24,25]

Chemical DVT prophylaxis (<48-72 hours) following traumatic brain injury with intracranial hemorrhage does not increase the progression of intracranial bleed.[26,27] Prior to starting chemical DVT prophylaxis, you should:

1. Consult a Neurosurgeon.

2. Obtain a stable CT scan of the head at 24 hours post injury.

Prophylaxis should be withheld in the setting of progression of intracranial hemorrhage or presence of an intracranial monitor.

Modification of enoxaparin dosing to 40mg daily in the combat casualty requiring an epidural pain catheter does not increase the incidence of venous thromboembolism.[28]

Inferior Vena Cava Filter (IVCF) placement in the combat theater may be used for:

1. Primary Prophylaxis (no evidence of VTE disease at the time of placement).

2. Secondary Prophylaxis (documented DVT) of PE in the polytrauma patient.

Patients felt to be at particularly **high risk for VTE development** and who have a clinical contraindication to prophylactic anticoagulation are the most likely to have an IVCF placed.

Most series examining the use of **IVCF placement for primary prophylaxis of PE** in the trauma patient support a low rate of subsequent PE (1.6%), although the studies are of variable design and a strong consensus supporting this clinical practice cannot be made based upon available data.[29]

There is no evidence that **prophylactic use of IVCF** is associated with a decreased PE rate or fatal PE rate. It should be noted that when IVCF are placed they are done so to prevent FATAL Pulmonary Emboli as DVT and PE still can occur.[30-34]

IVCF has no benefit in the prevention of DVTs and may be associated with the development of IVC and Deep Venous Thrombosis.[14,35]

RETRIEVABLE INFERIOR VENA CAVA FILTERS (RIVCF)

The vast majority of IVCF devices placed in the combat theater are Retrievable Inferior Vena Cava Filters (RIVCF).

RIVCF are preferred to avoid some of the long-term complications of filter placement. Additionally, many patients only need this form of VTE prophylaxis for a defined period of time early after injury.

Despite successful removal of IVCF beyond 180 days and high success and low complication rate for attempted **IVCF removal**, rates of eventual removal of RIVCFs in multiple studies of trauma patients in the United States have been as low as 14% to 22%.[36,37,38,39,40]

Combat injured patients from Operation Iraqi Freedom (OIF) and Operation Enduring Freedom (OEF) who had RIVCFs placed have an overall retrieval rate of 18%.[41]

It should be noted however; that the majority of patients was lost to follow up or did not have filters removed due to ongoing indications for use (82%). Therefore, the overall retrieval technical success rate may be much higher. Most series support removal of the most commonly used RIVCFs as early as they are no longer necessary and no later than approximately three months.[42] While it is possible to remove any of these later than this time period, the technical success declines significantly as potential complications associated with removal increase. Clear electronic documentation and a dedicated tracking system at the final CONUS MTF must be in place to improve retrieval rates and minimize loss to follow up.[43]

EDUCATION AND TREATMENT

Refer to Appendix A for specific guidance on different subsets of patients after various surgical procedures.

Refer to Appendix B for additional recommendations regarding IVC filters.

AEROMEDICAL EVACUATION CONSIDERATIONS

1. Aeromedical Evacuation (AE) from any area of responsibility to continental U.S. can require multiple flights over the course of days before the patient arrives at his or her final destination.
2. There is a clear association between long-distance travel and an increased risk of VTE, even in a "healthy traveler."
    3. Stresses of flight such as prolonged immobility and decreased humidity may contribute to VTE formation, especially in groups who already carry a high risk (trauma patients, recent surgeries, long bone fractures, smokers, pregnancy or post-partum, recent Myocardial Infarction, active cancer, presence of splint or cast, etc.).
4. Prophylaxis is essential to reduce the risk of VTE associated morbidity and mortality in all AE patients.
    a. AE crews will encourage patient ambulation every 2 hours for patients whose condition allows.
    b. SCD use should be universal for inpatients unless contraindicated by injury pattern. The Kendal SCD Express compression system is approved for use on military aircraft.
    c. Chemical VTE prophylaxis is also recommended as above for all trauma or medical inpatients unless specifically contraindicated by the medical condition such as ongoing bleeding or coagulopathy.
5. AE Patients with KNOWN acute VTE should be treated prior to flight unless there is a clear contraindication.
    a. Treatment depends on the clinical situation, but may include low-molecular-weight Heparin, Fondaparinux, oral Xa inhibitors, or Unfractionated Heparin.
    b. Oxygen and continuous pulse-oxygenation monitoring should be available during AE for patients with known VTE in case supportive measures are needed.

c. In the case of known or suspected Pulmonary Embolism, a Cabin Altitude Restriction should be considered to mitigate the effects of altitude on oxygenation and respiration.
d. Addition of a Critical Care Air Transport Team should also be considered in cases of PE with significant respiratory or hemodynamic compromise.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All trauma patients admitted to Role 2 or higher.

INTENT (EXPECTED OUTCOMES)

1. All patients in population of interest receive DVT prophylaxis with sequential compression device within 24 hours of injury.

2. All patients in population of interest start chemoprophylaxis (Heparin, Lovenox) within 48 hours of injury or contraindication documented.

3. When IVCF is inserted, there is documentation in the medical record regarding the indication for procedure, whether the IVCF is retrievable, manufacturer, brand, serial number, lot number, and exact location of placement.

4. Retrievable IVC filters are removed within 6 months.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who start DVT prophylaxis with sequential compression device within 24 hours of injury.

2. Number and percentage of patients in the population of interest who receive DVT chemoprophylaxis within 48 hours (Heparin, Lovenox) or have contraindication documented.

3. Number and percentage of patients who receive IVC filter placement who have complete documentation of indication for procedure, whether the IVCF is retrievable, manufacturer, brand, serial number, lot number, and exact location of placement.

4. Number and percentage of retrievable IVC filters placed that are removed within 6 months.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the Joint JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

All Health Care Providers will:

- Become familiar with the guidelines for the prevention of DVT (see Appendix A).
- Appropriately manage patients who may be at risk of developing DVT.
- Provide feedback on these guidelines and suggestions for changes to the CPG to the JTS Chief.

The senior surgeon and/or Intensivist at each Role 3 facility will:

- Review all thromboembolic events in the Level III facility to assess ways to reduce the risk to the patient.
- Coordinate with the JTS Performance Improvement Division Chief on the appropriateness of the guidelines being used and provide input for updates on an as needed basis.

APPENDIX A: PREVENTION OF VENOUS THROMBOEMBOLISM GUIDELINES

RISK GROUP	PROPHYLACTIC MEASURES
TRAUMA PATIENTS	
▪ Emergency trauma surgical procedures in patients with prohibitive risk of bleeding, or ongoing coagulopathy	▪ SCD (sequential compression device) until able to be anticoagulated (ideally start Lovenox within 12 hours of cessation of coagulopathy); see IVC filter and Duplex screening sections below.
▪ Emergency trauma surgical procedures in all patients, except patient with prohibitive risk of bleeding (once coagulopathy not present)	▪ SCD (unless contraindicated by injury) + Lovenox 30 mg SC BID or 40mg SC QD; alternatively Heparin 5000 U SC q 8 hours
▪ Isolated major orthopedic surgery of extremities, spine, and pelvis	▪ SCD (unless contraindicated by injury) + Lovenox 30 mg SC BID
IVC FILTER PLACEMENT	
Patients with: 1. Recurrent PE despite full anticoagulation 2. Proximal DVT and contraindications for full anticoagulation 3. Proximal DVT and major bleeding while on full anticoagulation 4. Progression of iliofemoral clot despite anticoagulation Patients with established DVT or PE and: 5. Large free-floating thrombus in the iliac vein or IVC 6. Following massive PE in which recurrent emboli may prove fatal 7. During/after surgical embolectomy Very High Risk Patients: those who cannot receive anticoagulation because of increased bleeding risk and : 8. Severe closed head injury (GCS<8) 9. Incomplete spinal cord injury with paraplegia or quadriplegia 10. Complex pelvic fractures with associated long-bone fractures 11. Multiple long-bone fractures	▪ Placement of retrievable IVC filter (RIVCF) ▪ **Document if the IVCF is retrievable or not, manufacturer, brand, MRI compatibility, serial number, lot number and exact location** in record and TMDS; PE may still occur despite IVC filter ▪ "Extended" indications for placement of IVC filter for patients with established DVT or PE ▪ Consideration of placement of prophylactic placement of IVC filter.
ROLE OF DUPLEX SCREENING	
▪ Asymptomatic patients	▪ Serial duplex ultrasound imaging of high-risk patients is not recommended.
▪ Symptomatic patients	▪ Duplex ultrasound may be used without confirmatory venography.
GENERAL, VASCULAR, UROLOGIC SURGERY	
LOW RISK:	
Minor procedure in patients < 40 years, no risk factors	Early mobilization
MODERATE RISK:	
▪ Minor procedure with additional risk factors for thrombosis; ▪ Non major surgery in patients 40-60 years, with no additional risk factors; ▪ Major surgery in patients < 40 years with no additional risk factors)	▪ SCD + Unfractionated Heparin 5000 units SCq 8 hours or Lovenox 40 mg SC QD ▪ Chemical DVT prophylaxis is withheld in patients with high risk of bleeding.

RISK GROUP	PROPHYLACTIC MEASURES
HIGH RISK:	
▪ Non major surgery in patients > 60 years or have additional risk factors; ▪ Major surgery in patients > 40 years or have additional risk factors	▪ SCD + Unfractionated Heparin 5000 units SC q 8 hours or Lovenox 40 mg SC QD ▪ Chemical DVT prophylaxis is withheld in patients with high risk of bleeding.
NEUROSURGERY	
▪ Intracranial neurosurgical procedures ▪ High Risk neurosurgery patients	▪ SCD ▪ SCD ▪ Chemical DVT prophylaxis following stable CT scan in consultation with neurosurgeon

APPENDIX B: IVCF RECOMMENDATIONS

1. All IVCFs placed in the combat theater should be retrievable.
2. Documentation detailing the ICVF brand, model, MRI compatibility, and exact location of placement should be documented in ALTHA T or TC2.
3. All RIVCFs placed in the combat theater should be removed as soon as contraindications to chemical prophylaxis of VTE disease no longer exist or there is no longer a need for VTE prophylaxis. Exceptions include those that were placed for secondary prophylaxis in a patient who demonstrated new VTE disease while on therapeutic anticoagulation or in patients who are still deemed to be high risk.
4. All RIVCFs should be removed within three months unless a long term indication for their continued use is present.
5. The decision to remove an RIVCF placed in the combat theater (versus leaving it in place permanently) should be made at the first CONUS Level V MTF the patient transitions through while returning from deployment. When possible, the removal should take place at this same facility prior to transition to the next level of care. This approach decreases the chance that a decision will be deferred until removal becomes technically prohibitive.
6. **The presence of a RIVCF in a patient receiving care at the Level IV MTF should be made known to the receiving Level V MTF. Typically, retrieval of the RIVCF will be accomplished at the Level V MTF.**
7. Any patient with a known DVT and without a current contraindication to therapeutic anticoagulation who has an IVCF in place should receive full dose anticoagulation. This is preferably accomplished with Coumadin to target an INR of 2.0-3.0. If further surgical procedures are planned, consideration may also be given to the use of low molecular weight heparin dosed at 1 mg/kg bid or an unfractionated heparin drip until such time as the use of Coumadin is felt to be appropriate.
8. The presence of an IVCF, brand, model, MRI compatibility, whether or not it is retrievable, its exact location and the date of insertion should be clearly annotated in TMDS and again in AHLTA when the patient has returned to the United States.
9. Efforts should be made in the future to standardize the type of RIVCF used at all combat theater locations.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

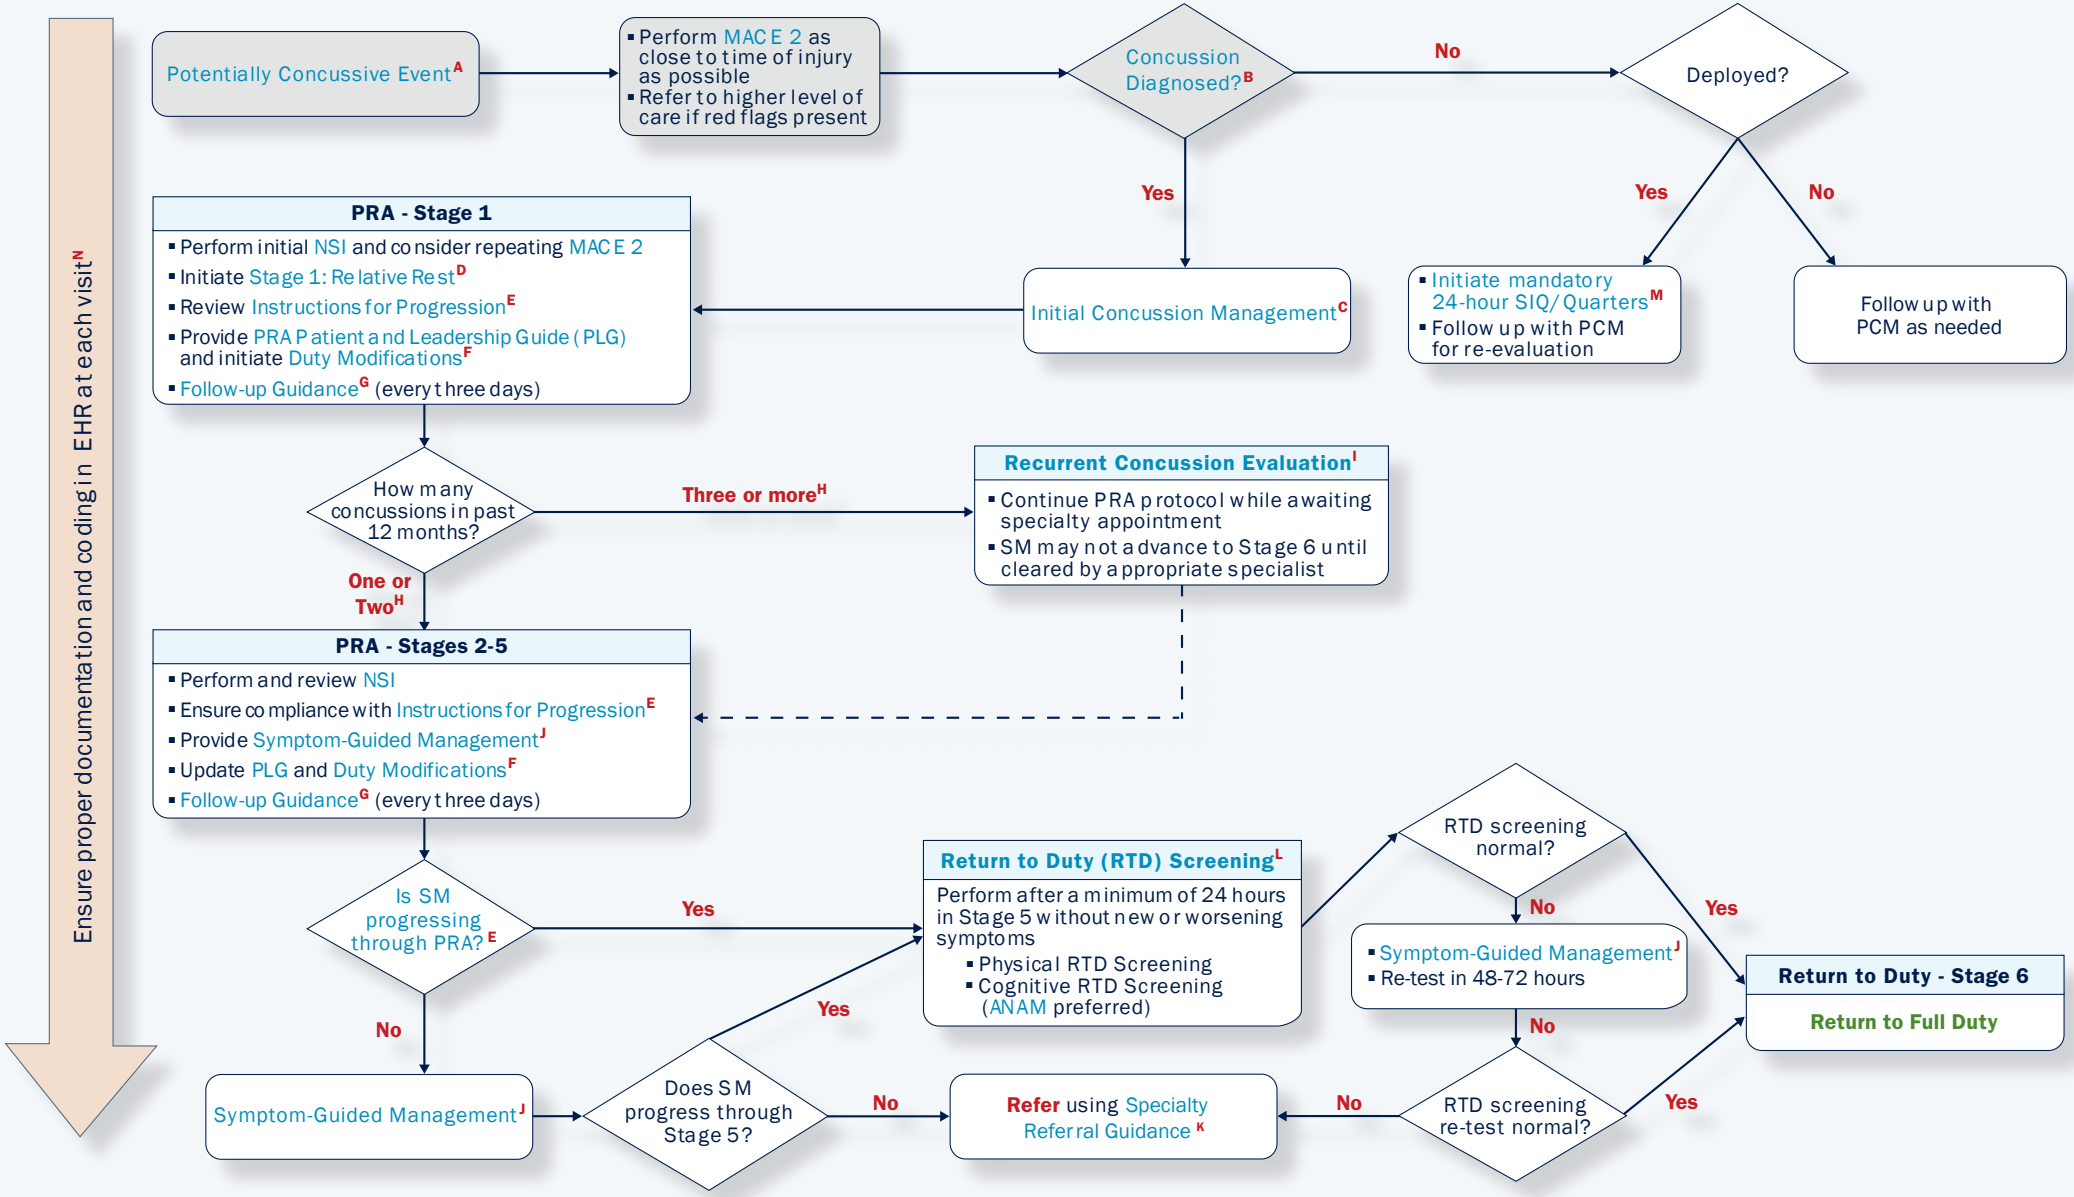
Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

MHS Military Health System
health.mil

Progressive Return to Activity Following Acute Concussion/Mild Traumatic Brain Injury

The algorithm below provides guidance on how to return a service member to full duty following a concussion. This is an interactive document. Please click the appropriate links in each box for detailed instructions and additional resources. To navigate back to this page use the 'Return to Algorithm' button at the bottom of each page.



Ensure proper documentation and coding in EHR at each visit[N]
Potentially Concussive Event[A]
Perform MACE 2 as close to time of injury as possible
Refer to higher level of care if red flags present
Concussion Diagnosed?[B]
No
Deployed?
Yes
No
Yes
Initial Concussion Management[C]
PRA - Stage 1
Perform initial NSI and consider repeating MACE 2
Initiate Stage 1: Relative Rest[D]
Review Instructions for Progression[E]
Provide PRA Patient and Leadership Guide (PLG) and initiate Duty Modifications[F]
Follow-up Guidance[G] (every three days)
Initiate mandatory 24-hour SIQ/Quarters[M]
Follow up with PCM for re-evaluation
Follow up with PCM as needed
How many concussions in past 12 months?
Three or more[H]
Recurrent Concussion Evaluation[I]
Continue PRA protocol while awaiting specialty appointment
SM may not advance to Stage 6 until cleared by appropriate specialist
One or Two[H]
PRA - Stages 2-5
Perform and review NSI
Ensure compliance with Instructions for Progression[E]
Provide Symptom-Guided Management[J]
Update PLG and Duty Modifications[F]
Follow-up Guidance[G] (every three days)
Is SM progressing through PRA?[E]
Yes
Return to Duty (RTD) Screening[L]
Perform after a minimum of 24 hours in Stage 5 without new or worsening symptoms
Physical RTD Screening
Cognitive RTD Screening (ANAM preferred)
RTD screening normal?
No
Yes
Symptom-Guided Management[J]
Re-test in 48-72 hours
Return to Duty - Stage 6
Return to Full Duty
No
RTD screening re-test normal?
No
Yes
No
Refer using Specialty Referral Guidance[K]
Does SM progress through Stage 5?
Yes
No
Symptom-Guided Management[J]

A. Potentially Concussive Event: Per DoDI 6490.11, events requiring mandatory rest periods and medical evaluations and reporting of exposure of all involved personnel include, but are not limited to:

- Involvement in a vehicle blast event, collision, or rollover
- Presence within 50 meters of a blast (inside or outside)
- A direct blow to the head or witnessed loss of consciousness
- Exposure to more than one blast event (the service member's commander shall direct a medical evaluation)

B. Concussion Diagnosis: 2015 DoD Definition of Traumatic Brain Injury: A traumatically induced structural injury or physiological disruption of brain function, as a result of an external force, that is indicated by new onset or worsening of at least one of the following clinical signs immediately following the event:

- Any alteration of mental status (e.g. confusion, disorientation, slowed thinking, etc.)
- Any period of loss of or a decreased level of consciousness, observed or self-reported
- Any loss of memory for events immediately before or after the injury

TBI Severity			
Criteria	**Mild/Concussion**	**Moderate**	**Severe**
Structural imaging	A CT scan is not indicated for most patients with a concussion*	Normal or abnormal	Normal or abnormal
Loss of consciousness (LOC)	0–30 minutes	>30 minutes and <24 hours	>24 hours
Alteration of consciousness (AOC)	up to 24 hours	>24 hours. Severity based on other criteria	
Post-traumatic amnesia (PTA)	0–1 day	>1 and <7 days	>7 days

* If obtained, the CT scan is normal

C. Initial Concussion Management: May be performed by first responder/medic/corpsman, emergency department provider, or PCM

- Provide concussion education and set expectations for full recovery
  - What You Should Know About Concussions
  - Healthy Sleep Following Concussion/mTBI
- Manage acute headache
  - Use acetaminophen every 6 hours for 48 hours followed by NSAIDs as needed
  - Delay use of NSAIDs for 48 hours after concussion
  - Avoid tramadol, acetaminophen/caffeine/butalbital, and opioids
  - Refer to Headache Following mTBI Clinical Recommendation for further guidance
- Review current medications and supplements
- Initiate 24-hour SIQ/Quarters
- Follow up with PCM in 24 hours

D. Relative Rest: Physical and cognitive activities that do not provoke symptoms

- Light physical activities
- Simple, familiar cognitive tasks
- Quiet environment with limited stimulation
- Healthy sleep and nutrition

Note: Stage 1 of the PRA consists of full-time relative rest. In Stages 2–5, service members should continue to utilize these guidelines to rest between more strenuous activities or if they exhibit any new or worsening symptoms.

E. Stages of the PRA: Instructions for Progression (Continued on next page)

Stage	Objective	Environment	Physical/Vestibular Activity	Cognitive/Oculomotor Activity	Restrictions Stages 1-5
Stage 1*: Relative Rest	Avoid symptom provocation, and rest to promote recovery	▪ Minimize light and noise ▪ Stay home/in quarters	▪ Daily activities that do not provoke symptoms ▪ Limit large or sudden changes in head position ▪ No exercise	▪ Limit screen time as needed to avoid symptom provocation ▪ Very light leisure activity (e.g. reading, television, conversation)	▪ Do not go outside the wire in a combat zone ▪ Maintain or reduce pre-injury levels of caffeine/energy drinks and nicotine ▪ No alcohol** ▪ No combatives or contact sports*** ▪ No driving until visual and vestibular symptoms have resolved ▪ No weapons fire or blast exposure***
Stage 2: Symptom-Limited Activity	Introduce and promote mild exertion	▪ Calm and familiar environment with limited distractions	▪ Limit large or sudden changes in head position ▪ Light routine exertion (e.g. walking on even terrain, light household chores, stationary bike) ▪ No weight or resistance training	▪ Simple, familiar activities performed one at-a-time (e.g. routine computer use, leisure reading)	
Stage 3: Light Activity	Introduce occupation-specific exertion and environmental distractions	▪ Introduce environmental distractions during activity ▪ Return to work on limited duty/profile without significant symptom provocation	▪ Initiate tasks requiring changes in head position ▪ Light aerobic exercise without resistance (e.g. elliptical, stationary bike, walking on uneven terrain) ▪ No lifting > 20 pounds ▪ No resistance training	▪ Simple, unfamiliar tasks or complex familiar tasks (e.g. grocery shopping, technical reading)	
Stage 4: Moderate Activity	Increase activity intensity and duration	▪ Distracting or busy environment during activity as tolerated	▪ Attempt tasks requiring more significant or sudden changes in head position ▪ Increase intensity and duration of activities (e.g. non-contact sports, hiking or running, push-ups, sit-ups) ▪ Introduce resistance training as tolerated	▪ Increase intensity and duration of activities (e.g. navigate busy environments, recall and follow complex instructions)	
Stage 5*: Intensive Activity**	Introduce exertion of duration and intensity that parallels service member's typical role ▪ Complete RTD Screening prior to advancement to Stage 6	▪ Typical daily environment EXCEPT listed restrictions	▪ Resume pre-injury exercise routine and training activities	▪ Complex problem solving or multi-tasking with exertion or distracting environment	
Stage 6: Return to Full Duty	Return to pre-injury activities	▪ Typical daily environment	▪ Unrestricted activity		

* Ensure SM adheres to Relative Rest guidelines and attempts to increase activity within 72 hours to avoid potentially detrimental effects of prolonged rest

** Alcohol use can exacerbate post-concussive symptoms of headache, depression, and anxiety and can cause impaired cognitive functioning, dehydration, and sleep disturbances

*** In Stage 5 the SM may gradually increase exposure to high risk activities in a *supervised* training environment based on mission requirements

E. Instructions for Progression:

- Review Stages of the PRA
- SM must spend at *least* 24 hours in each stage
- At the beginning of each day the SM should self-evaluate their symptoms
  - If symptoms are the **same as or better** than the previous day AND there are no **new** symptoms, advance to the next stage
  - If symptoms are **worse** OR there are **new symptoms**, remain in current stage for an additional 24 hours
  - For patients that are not improving or worsening, reference Follow-up Guidance, Symptom-Guided Management, or Specialty Referral Guidance
- If symptoms worsen during an activity, the SM should follow the guidelines for Relative Rest until the exacerbation resolves, and then return to the previously tolerated stage for the remainder of the day
- After 24 hours in Stage 5 without new or worsening symptoms, the SM should follow up with PCM for Return to Duty Screening

F. Duty Modifications:

- The Patient and Leadership Guide (PLG) provides answers to common questions that command leadership may have regarding the PRA process and duty modifications. In addition, it outlines activities that the SM should and should not perform for each stage of the PRA.
- Ensure that the PLG is given to every SM with a concussion and communicated with their chain of command.
- Policies and procedures are service and command specific. Consult duty and deployment standards for your organization when dispositioning patient.
- Specific restrictions based on the patient's MOS/NEC/AFSC, individual injury characteristics, or any other factors should be annotated on the chit/profile as well as any reasons for lack of adherence to uniform standards.

G. Follow-up Guidance:

- Schedule follow-up appointments every 3 days or sooner if symptoms acutely worsen
  - Consider virtual, telephone, or clinical support staff follow-ups if feasible in your practice setting
- If service member does not advance through a single stage for 3 consecutive days, upon follow-up:
  - Ensure compliance with activity recommendations
  - Refer to Symptom-Guided Management
- If symptoms persist >15 days, consult Specialty Referral Guidance

H. Multiple Concussion Guidance: Required for deployed SMs per DoDI 6490.11, and recommended for SMs in garrison

- **Two concussions in the last 12 months**:
  - SM must spend a minimum of 7 days in the PRA protocol prior to RTD Screening
- **Three or more concussions in the last 12 months**:
  - Refer for Recurrent Concussion Evaluation
  - Continue PRA protocol while awaiting specialty appointment
  - SM can only be returned to full duty (Stage 6) by a specialist
- For imaging recommendations refer to the Neuroimaging Following Mild TBI Clinical Recommendation

I. Recurrent Concussion Evaluation: Required for SMs who have sustained 3 or more concussions in a 12-month span

J. Symptom-Guided Management:

- The following table provides recommendations and resources for how to treat the most common symptoms associated with concussion.

Symptom Cluster	Signs and Symptoms	Evaluation	Primary Care Management
Anxiety/ Mood	▪ Depression/feeling sad ▪ Irritability ▪ Low tolerance to frustration ▪ Mood changes/lability ▪ Nightmares	▪ GAD-7 ≥10 ▪ NSI questions 17–22 ▪ PHQ-9 ≥10	▪ Refer immediately to Behavioral Health for any concerns about harm to self or others ▪ Consider acute intervention in cases of acute stress reaction: education, reassurance of safety, normalization, acute symptom management, social support ▪ Non-pharmacologic: mindfulness, deep breathing and relaxation, pleasurable activities, exercise (if appropriate) ▪ Depression Resources ▪ Primary Care Behavioral Health Clinical Pathways ▪ VA/DoD PTSD and ASD CPG
Cervical	▪ Dizziness (cervicogenic) ▪ Headache ▪ Neck pain ▪ Numbness	▪ Physical exam	▪ Non-pharmacologic: Traditional Chinese or Medical Acupuncture ▪ Pharmacologic: acetaminophen every 6 hours for up to 48 hours post-concussion followed by NSAIDs as needed; avoid tramadol, acetaminophen/caffeine/butalbital, and opioids ▪ Dizziness Following mTBI Clinical Recommendation ▪ Headache Following mTBI Clinical Recommendation
Cognitive	▪ Confusion/foggy thinking ▪ Delayed response ▪ Difficulty concentrating ▪ Difficulty with memory/forgetfulness	▪ MACE 2 cognitive score <25 ▪ NSI questions 13–16	▪ If there are any concerns about cognition, confirm patient report of symptoms and performance with third party when possible ▪ Physical and sleep-related symptoms may impact cognitive function- identify and treat contributing conditions ▪ Cognitive Rehabilitation Following mTBI Clinical Recommendation
Headache	▪ Auras ▪ Neck pain ▪ Numbness, tingling, weakness ▪ Phonosensitivity ▪ Photosensitivity	▪ HIT-6 ≥50 ▪ NSI questions 4–7, 9, 11	▪ Non-pharmacologic: Traditional Chinese or Medical Acupuncture ▪ Pharmacologic: acetaminophen every 6 hours for up to 48 hours post-concussion followed by NSAIDs as needed; avoid tramadol, acetaminophen/caffeine/butalbital, and opioids ▪ Headache Following mTBI Clinical Recommendation
Oculomotor	▪ Blurry vision ▪ Decreased attention for visual tasks ▪ Difficulty reading (paper or screen) ▪ Double vision ▪ Eye strain ▪ Headache ▪ Photosensitivity	▪ NSI questions 4, 6, 7 ▪ VOMS Abnormal Smooth Pursuits, Saccades, or Convergence testing	▪ Oculomotor symptoms often spontaneously resolve within a few weeks after injury ▪ Visual Dysfunction Following mTBI Clinical Recommendation ▪ VOMS Visual Guide
Sleep	▪ Difficulty falling/staying asleep ▪ Excessive daytime sleepiness ▪ Fatigue ▪ Nightmares ▪ Sleeping too much or too little	▪ ESS >10 ▪ ISI >11 ▪ NSI questions 17, 18	▪ Sleep disruption can exacerbate other symptom clusters and may prolong recovery ▪ Sleep Disturbances Following mTBI Clinical Recommendation
Vestibular	▪ Decreased coordination ▪ Dizziness/vertigo ▪ Loss of balance ▪ Motion sensitivity ▪ Nausea ▪ Nystagmus	▪ NSI questions 1–3, 8 ▪ VOMS Abnormal Vestibular/Ocular Reflex or Visual Motion Sensitivity testing	▪ If appropriate, evaluate and treat benign paroxysmal positional vertigo ▪ Dizziness Following mTBI Clinical Recommendation ▪ VOMS Visual Guide

K. Specialty Referral Guidance:

- Patients who do not respond to initial management and have symptoms persisting >15 days may benefit from referral to TBI specialty clinic, if available, or specialties listed below.

Symptom Cluster	Specialty Referral
Anxiety/ Mood	**Behavioral Health** ▪ Consider early referral in cases of acute stress reaction that do not rapidly resolve with simple measures ▪ Evaluation of new or premorbid behavioral health conditions
Cervical	**Physical Medicine and Rehabilitation (PM&R)** ▪ Assessment of persistent neck pain with comorbid chronic pain or persistent headache secondary to musculoskeletal dysfunction **Physical Therapy** ▪ Assessment and treatment of persistent neck pain following mTBI
Cognitive	**Neuropsychology** ▪ Formal evaluation to determine a need for work/home/school accommodations **Occupational Therapy** ▪ Strategies for daily living, functional cognition interventions, adaptive equipment/technology, driving evaluations **Speech Language Pathology** ▪ Cognitive rehabilitation strategies, speech disfluencies, organizational strategies
Headache	**Neurology** ▪ Assessment of persistent headaches when: (a) the diagnosis is not clear, (b) headaches do not respond to traditional treatment or prevention strategies, (c) there is a significant unresolved disability due to headache, (d) prolonged or persistent aura, or (e) headaches with accompanied motor weakness **Neuro-Optometry** ▪ Evaluation of headaches secondary to visual changes or eye strain **Physical Medicine and Rehabilitation (PM&R)** ▪ Assessment of persistent headaches with comorbid chronic pain or persistent headache secondary to musculoskeletal dysfunction
Oculomotor	**Neuro-Optometry** ▪ Assessment of visual disturbances that started or worsened after mTBI **Occupational Therapy** ▪ Strategies for daily living, functional vision interventions, adaptive equipment/technology, driving evaluations
Sleep	**Behavioral Health** ▪ Evaluation of behavioral health conditions that may impact sleep **Sleep Medicine** ▪ Evaluation of persistent or chronic sleep disturbance
Vestibular	**Vestibular Therapy** ▪ Specialized physical or occupational therapy to alleviate dizziness and other problems associated with vestibular disorders

L. Return To Duty (RTD) Screening:

- Before returning to full duty, SM should pass the Physical AND Cognitive RTD Screenings to ensure mission readiness.
- These tests should be performed after the service member has spent a minimum of 24 hours in Stage 5 without new or worsening symptoms.
- The purpose of the RTD screening is to give the provider a way to objectively measure readiness for return to duty. This may be used in conjunction with patient's subjective history of tolerated physical and cognitive activities.
- Consider MOS/NEC/AFSC service specific return to duty requirements (e.g. flight status, dive status, jump status, etc.) prior to RTD.

Physical RTD Screening:

- Physical exertion testing may be done in office, gym, or PT area.
- Have the service member perform 2 minutes of supervised aerobic activities at an exertion rate of 16 or greater on Borg RPE (Appendix C).
  - Preferred activities include modified burpees, sit-ups, or jumping jacks, as these activities will stress the vestibular system. Other activities may include high-knees, step-ups, push-ups, running, elliptical, or exercise bike.
  - Consider simulating combat environment if in a deployed setting.
  - Consider integrating MOS/NEC/AFSC specific-tasks and duty requirements.
- During exertion, observe service member for overt symptom provocation. If symptoms worsen, stop the test:
  - Remain in Stage 5 and re-test in 48–72 hours as appropriate.
  - Refer to Symptom-Guided Management while awaiting re-test.
- If the re-test is abnormal, refer to higher level of care based on Specialty Referral Guidance.
- If the Physical RTD Screening is normal, proceed to the Cognitive RTD Screening.

Cognitive RTD Screening:

- The preferred neurocognitive screening is the Automated Neuropsychological Assessment Metrics (ANAM). If ANAM is unavailable, repeat the Cognitive Exam portion of the MACE 2 (Questions 5–16).
- See ANAM Guidance (Appendix D) for further information.

M. Mandatory 24-hour SIQ/Quarters: Per DoDI 6490.11, service members involved in a potentially concussive event during deployment are required to rest for 24 hours, beginning at the time of the event. In certain circumstances, these recommendations can be superseded based on commanders' determination of mission requirements.

N. TBI Coding Guidance: Refer to TBICoE online resource for specific coding instruction.

Appendix A: Neurobehavioral Symptom Inventory (NSI)

Neurobehavioral Symptom Inventory (NSI)
Instructions: Please rate the following symptoms with regard to how much they have disturbed you **SINCE YOUR INJURY**.
0 = None: Rarely if ever present; not a problem at all.
1 = Mild: Occasionally present, but it does not disrupt my activities; I can usually continue what I'm doing; doesn't really concern me.
2 = Moderate: Often present, occasionally disrupts my activities; I can usually continue what I'm doing with some effort; I feel somewhat concerned.
3 = Severe: Frequently present and disrupts activities; I can only do things that are fairly simple or take little effort; I feel I need help.
4 = Very Severe: Almost always present and I have been unable to perform at work, school or home due to this.

Symptom	**None**	**Mild**	**Moderate**	**Severe**	**Very Severe**
1. Feeling dizzy	0	1	2	3	4
2. Loss of balance	0	1	2	3	4
3. Poor Coordination, clumsy	0	1	2	3	4
4. Headaches	0	1	2	3	4
5. Nausea	0	1	2	3	4
6. Vision problems, blurring, trouble seeing	0	1	2	3	4
7. Sensitivity to light	0	1	2	3	4
8. Hearing difficulty	0	1	2	3	4
9. Sensitivity to noise	0	1	2	3	4
10. Numbness or tingling on parts of my body	0	1	2	3	4
11. Change in taste and/or smell	0	1	2	3	4
12. Loss of appetite or increased appetite	0	1	2	3	4
13. Poor concentration, can't pay attention, easily distracted	0	1	2	3	4
14. Forgetfulness, can't remember things	0	1	2	3	4
15. Difficulty making decisions	0	1	2	3	4
16. Slowed thinking, difficulty getting organized, can't finish things	0	1	2	3	4
17. Fatigue, loss of energy, getting tired easily	0	1	2	3	4
18. Difficulty falling or staying asleep	0	1	2	3	4
19. Feeling anxious or tense	0	1	2	3	4
20. Feeling depressed or sad	0	1	2	3	4
21. Irritability, easily annoyed	0	1	2	3	4
22. Poor frustration tolerance, feeling easily overwhelmed by things	0	1	2	3	4
The purpose of this inventory is to track symptoms over time. Please do not attempt to score.					

Cicerone, K. D., & Kalmar, K. (1995). Persistent postconcussion syndrome: The structure of subjective complaints after mild traumatic brain injury. *Journal of Head Trauma Rehabilitation*, 10, 1–17. https://dx.doi.org/10.1097/00001199-199510030-00002

Appendix B: Patient and Leadership Guide (PLG)

Progressive Return to Activity Following Concussion/mTBI Patient and Leadership Guide (PLG)

FROM: _____ **TO:** _____ **DATE:** _____

RANK/NAME/UNIT: _____ **DoD ID#:** _____

DIAGNOSIS: Concussion/mTBI **Signature:** _____

DUTY STATUS:

Quarters: ❑ 24 hours ❑ 48 hours ❑ 72 hours

Light Duty/Profile (per stages chart) for ___ days

Follow-up Dates/Times: _____

NOTES: _____

_____

_____

Follow-up:

The above service member (SM) has been diagnosed with a concussion, or mild traumatic brain injury (mTBI), and will be following the TBICoE Progressive Return to Activity (PRA) Protocol throughout recovery. This process is unique in that the SM will progress at their own pace through the protocol but will have a **scheduled follow-up** with their provider **every three days**. Here are a few common questions related to concussions and this process:

What is the PRA?

The PRA is a six-step return to activity protocol. The earliest a SM can be returned to full duty after concussion is seven days. Following a gradual return to duty protocol has been shown to get SMs back to full duty safely and reduce long-term complications.

What could happen if a SM returns to duty too soon?

Returning a SM too soon places the SM and their unit at risk. Concussion can cause temporary disruption of mental and physical functioning, impairing reaction time, balance, marksmanship, etc. The SM should return to their primary care manager (PCM) and undergo a Return to Duty Screening before they may be returned to full duty.

What are common concussion symptoms?

Thinking/Remembering	Physical		Emotional/Mood	Sleep
Difficulty concentrating	Balance problems	Dizziness	Irritability	Excessive daytime sleepiness
Difficulty remembering new information	Feeling tired, having no energy	Fuzzy or blurry vision, difficulty reading	More emotional	Sleeping less than usual
Difficulty thinking clearly	Headache	Nausea or vomiting (early on)	Nervousness or anxiety	Sleeping more than usual
Feeling slowed down	Sensitivity to noise or light		Sadness	Trouble falling or staying asleep

What is the average recovery time from concussion/mTBI? When can the SM go back to work?

Most SMs fully recover from concussion. Recovery is different for each person, but most people are back to full duty in 2–4 weeks and will be treated solely by their PCM. However, some SMs may experience more severe symptoms that take longer to resolve and require a referral to a TBI Clinic or specialist.

How does a SM progress through the stages of the PRA?

The SM must spend at least 24 hours in each stage. At the beginning of each day the SM should evaluate how they feel:

- If symptoms are the same or better compared with the previous day **AND** they have no *new* symptoms — **they can move on to the next stage**
- If symptoms are worse compared with the previous day **OR** they have *new* symptoms – **they remain at the current stage for an additional 24 hours**

What does a SM do if there are new or worsening symptoms during the day?

Stop the activity until symptoms resolve. Then, return to the previously tolerated stage for the remainder of the day. The next day, reevaluate symptoms and continue progression through the PRA. Contact the provider with any questions or concerns.

Appendix B: Patient and Leadership Guide (PLG)

Stages of Progressive Return to Activity				
Stage	**Things Service Member *Should* Do**		**Things Service Member *Should Not* Do**	
Stage 1 – Relative Rest	▪ Light physical activities that don't make symptoms worse (e.g. walking at easy pace) ▪ Light leisure activities that don't make symptoms worse (e.g. TV, reading)	▪ Communicate with friends and family members for support ▪ Eat a healthy diet and drink plenty of water ▪ Get plenty of sleep, and take naps as needed in the early stages ▪ Maintain or reduce use of caffeine, energy drinks, and nicotine ▪ Take breaks if needed	▪ Do not go to work (SIQ/ Quarters) ▪ No physical training or exercise	▪ Do not go outside the wire in a combat zone ▪ No alcohol ▪ No combatives or contact sports ▪ No driving until dizziness or visual symptoms have resolved ▪ No weapons fire or blast exposure
Stage 2 – Symptom-Limited Activity	▪ Increase your physical activity (e.g. take a walk, ride a stationary bike without resistance, do light household activities) ▪ Light reading/computer work as tolerated		▪ Avoid crowded areas ▪ Avoid extreme temperatures ▪ No group physical training ▪ No resistance/weight training	
Stage 3 – Light Activity ▪ SM may be able to return to work at this stage with limitations based on symptoms	▪ Increase physical activities (e.g. elliptical or stationary bike without resistance, walk further, lift or carry light loads of less than 20 pounds) ▪ More technical reading and computer work, go out in more crowded areas (e.g. grocery shopping) ▪ Start military specific tasks (e.g. clean equipment, perform maintenance checks, clean weapons)		▪ No operating heavy machinery ▪ No resistance/weight training ▪ No riding in tactical vehicles ▪ No alternating shift work or shifts > 8 hours	
Stage 4 – Moderate Activity	▪ Increase physical activities (e.g. non-contact sports, hiking or running, resistance training as tolerated (e.g. push-ups, sit-ups), carry weight across uneven terrain) ▪ Increase complexity of military specific tasks (e.g. orienteering/land navigation, following complex instructions, begin wearing personal protective equipment as tolerated)		▪ No operating heavy machinery ▪ No riding in tactical vehicles ▪ No alternating shift work or shifts > 8 hours	
Stage 5 – Intensive Activity ▪ SM to follow up with PCM for Return to Duty Screening	▪ Gradually increase exposure to high risk activities (e.g. combatives, weapons fire or blast exposure, contact sports) in a supervised training environment based on mission requirements ▪ Resume usual exercise routine and military tasks/ training (e.g. use night vision goggles, take part in simulations, navigate uneven terrain/busy environment with flak jacket/Kevlar helmet/pack)		▪ No alternating shift work or shifts > 8 hours	
Stage 6 – Return to Full Duty	▪ Unrestricted activity			

Appendix C: Borg Rate of Perceived Exertion (RPE) Scale

Instructions: The Borg Rate of Perceived Exertion (RPE) is a way of measuring physical activity intensity level. When conducting the Physical RTD Screening, have the service member begin the activity and ask them to rate their level of exertion using the Borg RPE. When they reach a 14-16, begin the two minute timer.

6	**No exertion at all**
7–8	**Extremely light**
9	**Very light** exercise. For a healthy person, it is like walking slowly at his or her own pace for some minutes
10-12	**Light**
13	**Somewhat hard** exercise, but it still feels OK to continue.
14-16	**Hard** (heavy)
17-18	**Very Hard**. A healthy person can still go on, but he or she really has to push him- or herself. It feels very heavy, and the person is very tired.
19	**Extremely strenuous** exercise level. For most people this is the most strenuous exercise they have ever experienced
20	**Maximal exertion**

Borg, G. (1982). Psychophysical bases of perceived exertion. *Medicine and Science in Sports and Exercise*, 14 (5), 377 – 81.

Appendix D: ANAM Guidance

How to Request ANAM

1. Call ANAM Help Desk
   - Phone number: 1-855-630-7849 (toll free)
   - Hours of Operation: 24 hours, 365 days
2. Send a request to ANAM Results Request Inbox (cannot be encrypted): usarmy.jbsa.medcom.mbx.otsg--anam-baselines@mail.mil

Interpretation of the ANAM Clinical Report

A. If service member **has a baseline ANAM**, refer to the Reliable Change scores for each subtest. If the Reliable Change is less than -1.64 on any one subtest (appearing in a red box), or less than -1.28 on 2 or more subtests, remain in Stage 5 and repeat ANAM in 48–72 hours.

B. If service member **does not have a baseline ANAM**, refer to the overall Composite Score. If the Composite Score is less than -1.64, remain in Stage 5 and repeat ANAM in 48-72 hours.

Example ANAM Report

-1.13 SR2-Simple Reaction Time (R) (Reaction Time)
B
COMPOSITE SCORE
-3 -2 -1 0 1 2 3
Score: -1.78

- If service member does not meet criteria for return to duty after second attempt, refer to Neuropsychologist/ Speech Language Pathologist (SLP) for further evaluation.
- The ANAM Help Desk can answer general questions. For questions regarding ANAM interpretation, please consult a Neuropsychologist or specialist.

If ANAM is unavailable, repeat the Cognitive Exam portion of the MACE 2 (Questions 5-16)

- SM should score > 25 to be considered ready to return to full duty.
- If SM scores ≤ 25, remain in Stage 5 and repeat in 48-72 hours.
- If the score continues to be ≤ 25, refer for ANAM (see above) or to Neuropsychologist/Speech Language Pathologist (SLP) for further evaluation.

Appendix E: PRA Frequently Asked Questions (FAQs)

Responses to frequently asked questions are listed below to assist providers in implementation of the PRA.

GENERAL:

Question: What is the PRA?

Answer: The PRA is a gradual, evidence-based protocol that facilitates return-to-duty in a six-stage process. The earliest a SM can progress through all six stages and be returned to full duty is 7 days after concussion.

Question: Why should I use a PRA protocol after concussion?

Answer: Following a step-wise return to duty protocol has been shown to get SMs back to full duty safely and reduce long-term complications. Returning a SM too soon places the individual and their unit at risk. Concussion can cause temporary disruption of mental and physical functioning, impairing reaction time, balance, marksmanship, etc. The SM should return to their medical provider and undergo a Return to Duty Screening before they may be returned to full duty.

Question: Which patients can benefit from the PRA?

Answer: The PRA is designed for use in active-duty SMs who have sustained a concussion/mTBI. However, the PRA is appropriate for concussion recovery in civilians or reservists and can be utilized by modifying the activities in each stage to meet the patient's needs or lifestyle.

PRA ALGORITHM & PROGRESSION:

Question: Why are the first 3 boxes of the algorithm shaded a different color from the rest of the algorithm and what is their significance?

Answer: The PRA CR has incorporated aspects of the MACE 2 and combined the 2014 PRA for Primary Care Managers, the 2014 PRA for Rehabilitation Providers, and the Concussion Management Tool (CMT) into the PRA Algorithm, creating a more comprehensive product to manage concussion from point of injury to return to full duty. The MACE 2 and components of the CMT are typically used prior to entering the PRA protocol. To indicate this, we shaded the initial management steps a different color. Often, these actions are taken by providers/corpsman/medics that are outside of the SM's usual medical facility (i.e. emergency department or branch clinic).

Question: What special considerations should I make with SMs that have sustained multiple concussions in the past 12 months?

Answer: When considering the number of concussions the patient has had in the past 12 months, include the current concussion in that number. Per DoDI 6490.11, deployed SMs who have experienced two concussions in the last 12 months must spend a minimum of seven days in the PRA protocol prior to return to full duty. SMs who have experienced 3 or more concussions in the last 12 months must be referred for Recurrent Concussion Evaluation. The SM must stop progression at Stage 5 and can only be returned to full duty (Stage 6) by a specialist.

Question: Why are SMs treated differently if deployed?

Answer: If a SM is exposed to a potentially concussive event (PCE) while *deployed*, DoD Instruction (DoDI) 6490.11 mandates 24 hours of rest. If the SM is exposed to a PCE while in *garrison* and *does not* meet criteria for a concussion (i.e. mechanism of injury and AOC, LOC, or PTA), 24 hours rest is not mandatory but is still encouraged.

Question: What would you recommend for a SM who is advancing in one area (e.g. physical activity) but struggling in another area (e.g. cognitive activity)?

Answer: A SM should tolerate activities in both physical/vestibular and cognitive/oculomotor categories prior to advancing to the next stage of the PRA. The PCM should use the Symptom-Guided Management table to address specific areas with high symptom burden.

Question: How do you treat a SM who has delayed in presenting to their PCM for days or weeks after a PCE?

Answer: First, determine if they have been evaluated for a concussion (e.g. in the emergency department) and if a MACE 2 has been completed. If a MACE 2 has not been completed, consider performing at the initial evaluation. Then enter the algorithm at the large rectangle labeled "Initiate PRA Stage 1." Follow the instructions, but rather than beginning at Stage 1, evaluate at which stage the SM should enter the PRA based on the timeframe since the injury and the SM's activity level and symptoms. Example: It has been seven days since the SM was injured and seen in the ED where a MACE 2 was performed and documented in the EHR. The SM's overall NSI score is very low (e.g. one for headache and one for dizziness and zeros for all other symptoms), and it is their first concussion in the past 12 months. They report being able to run a half mile before feeling a worsening headache and being able to do push-ups, pull-ups, and light resistance training. Based on these criteria, the SM could enter the PRA at Stage 4 and progress per regular instructions.

Question: I'm concerned that my patient won't be able to see me every three days. Are there recommendations for how to accomplish this?

Answer: We strongly recommend scheduling at least five follow-up appointments (every three days) at their first visit. Since the average recovery time for concussion is 15 days, this allows the SM to provide dates and times to their chain of command for awareness and planning. Most patients will complete the entire PRA progression in this time period, though some may require additional recovery time (see risk factors for protracted recovery below). You can also consider utilizing telehealth appointments with the PCM or trained support staff to complete follow-up visits. However, RTD screening will require an in-person appointment.

Appendix E: PRA Frequently Asked Questions (FAQs)

RETURN TO DUTY CONSIDERATIONS:

Question: What is the Borg scale and how does it compare to heart rate monitoring during exercise?

Answer: The Borg Rating of Perceived Exertion (RPE) scale helps estimate how hard someone is working (activity intensity). The Borg RPE can be multiplied by 10 to get a fairly good estimate of the individual's actual heart rate.[1] For example, if the SM is on a treadmill and reports a 13 (Somewhat hard, but it still feels OK to continue), their estimated heart rate would be 13 x 10 = 130 bpm. Because this is only an *approximation* of heart rate, the actual heart rate can vary depending on age and physical condition.

Question: Why is the ANAM part of the RTD screening? What if the ANAM is not available in my setting?

Answer: Growing evidence supports the importance of both cognitive and physical readiness for return to duty. The ANAM is a neurocognitive assessment tool that has been normed and validated in military SMs. Additionally, many SMs have a baseline ANAM score from before their concussion, which allows for comparison. Thus, the ANAM provides the best evaluation of a SM's cognitive function in relation to their peers and their own pre-concussion performance. If the ANAM is not available, you can either refer to a nearby MTF that has ANAM testing or repeat the cognitive exam portion of the MACE 2.

Question: I'm deployed, and we need the SM back to duty before they have completed the full PRA for mission readiness. What should I do?

Answer: This clinical recommendation is intended to serve as a guideline, and while strongly encouraged to promote a safe recovery for concussed SMs, these recommendations may be superseded at medical or command discretion.

ADDITIONAL CONSIDERATIONS:

Question: Why should we avoid using tramadol, acetaminophen/caffeine/butalbital, and opioids in the acute stages of concussion?

Answer: All of these medications can cause CNS depression and alter cognitive function, which can mimic other conditions associated with traumatic brain injury (e.g. intracranial bleed) and obscure the clinical course of TBI. The sedating effects of these medications can also be intensified in patients with head injury.[2] In addition, all of these medications carry high risk of dependence, tolerance, and medication overuse (rebound) headaches. Lastly, tramadol and opioids can cause nausea and vomiting, and tramadol may increase the risk of seizures.

Question: Why should we wait 48 hours before using nonsteroidal anti-inflammatory drugs (NSAIDs) for treatment of post-traumatic headache?

Answer: Use of NSAIDs for post-traumatic headache should be delayed for 48 hours following concussion due to their anti-platelet effect and the potential risk of exacerbating an evolving intracranial bleed.

Question: Why should SMs minimize consumption of caffeine/energy drinks and nicotine and avoid alcohol after a concussion?

Answer: There is limited evidence on the impact of caffeine, energy drinks, nicotine, and alcohol on concussion recovery. However, these substances can cause dehydration, disrupt sleep patterns, and worsen post-concussion symptoms resulting in a delay in return to duty. Abrupt cessation of caffeine or nicotine may result in withdrawal symptoms, therefore, we recommend SMs minimize or maintain their pre-injury levels of these substances. We recommend abstinence from alcohol as any use may exacerbate concussion symptoms including headache, dizziness, nausea, vomiting, fatigue, cognitive disturbances, depression and anxiety. Additionally, excessive alcohol use may increase fall risk, which places a SM at higher risk for a 2nd concussion.

Question: My patient is not progressing or is progressing very slowly. What are the risk factors for protracted recovery?

Answer: There are several risk factors, both pre- and post-traumatic, associated with protracted recovery following concussion. The most consistent predictor of delayed recovery is the severity of acute and subacute symptoms.[3] Pre-traumatic factors include female sex, history of concussion, migraine headaches, sleep disorders, and psychological conditions (including PTSD, anxiety, depression, ADHD, and substance abuse).[4,5,6] Post-traumatic factors include post-traumatic migraine/headache and acute dizziness.[3,4] Particularly relevant in the military population is the prevalence of PTSD and its potential impact on concussion recovery. The risk for PTSD is elevated two-to-three fold following concussion, and the prevalence of co-morbid PTSD and TBI has been reported to range from 10-40%.[7,8] During early concussion care, providers should be aware of risk factors for PTSD, including acute stress disorder (ASD), which is diagnosed when acute stress reaction (ASR) or combat or operational stress reaction (COSR) persists beyond three days. Refer to the VA/DoD PTSD and ASD Clinical Practice Guideline for more information on ASR, ASD, and PTSD.

Question: When is it safe for a SM to have sexual intercourse following a concussion?

Answer: Sexual activity can be slowly reintroduced, as with other strenuous activity, during progression through the stages. It is safe to have sex when the SM is able to do so without exacerbating symptoms. Consider fatigue, mood, and dizziness in addition to other physical symptoms. During recovery, SMs may wish to modify sexual activity (e.g. position, frequency, intensity) in order to minimize symptoms.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Prolonged Casualty Care Guidelines (CPG ID:91)

The Prolonged Casualty Care (PCC) guidelines are a consolidated list of casualty-centric knowledge, skills, and best practices intended to serve as the DoD baseline clinical practice guidance to guide casualty management over a prolonged amount of time in austere, remote, or expeditionary settings, and/or during long-distance movements.

PROLONGED CASUALTY CARE BACKGROUND

***Prolonged Casualty Care (PCC)**: The need to provide patient care for extended periods of time when evacuation or mission requirements surpass available capabilities and/or capacity to provide that care.*

The PCC guidelines are a consolidated list of casualty-centric knowledge, skills, abilities, and best practices intended to serve as the DoD baseline clinical practice guidance (CPG) to direct casualty management over a prolonged period of time in austere, remote, or expeditionary settings, and/or during long-distance movements. These PCC guidelines build upon the DoD standard of care for non-medical and medical first responders as established by the Committee on Tactical Combat Casualty Care (CoTCCC), outlined in the Tactical Combat Casualty Care (TCCC) guidelines,[1] and in accordance with (IAW) DoDI 1322.24.

The guidelines were developed by the PCC Work Group (PCC WG). The PCC WG is chartered under the Defense Committee on Trauma (DCoT) to provide subject matter expertise supporting the Joint Trauma System (JTS) mission to improve trauma readiness and outcomes through evidence-driven performance improvement. The PCC WG is responsible for reviewing, assessing, and providing solutions for PCC-related shortfalls and requirements as outlined in DoD Instruction (DoDI) 1322.24, *Medical Readiness Training, 16 Mar 2018*, under the authority of the JTS as the DoD Center of Excellence pursuant to DoDI 6040.47, *JTS*, 05 Aug 2018.

Operational and medical planning should seek to avoid categorizing PCC as a primary medical support capability or control factor during deliberate risk assessment; however, an effective medical plan always includes PCC as a contingency. Ideally, forward surgical and critical care should be provided as close to casualties as possible to optimize survivability.[2] DoD units must be prepared for medical capacity to be overwhelmed, or for medical evacuation to be delayed or compromised. When contingencies arise, commanders' casualty response plans during PCC situations are likely to be complex and challenging. Therefore, PCC planning, training, equipping, and sustainment strategies must be completed prior to a PCC event. The following evidence-driven PCC guidelines are designed to establish a systematic framework to synchronize critical medical decisions points into an executable PCC strategy, regardless of the nature of injury or illness, to effectively manage a complex patient and to advise commanders of associated risks.

The guidelines build upon the accepted TCCC categories framed in the novel MARC^{2}H^3-PAWS-L treatment algorithm, (Massive Hemorrhage/MASCAL, Airway, Respirations, Circulation, Communications, Hypo/Hyperthermia and Head Injuries, Pain Control, Antibiotics, Wounds (including Nursing and Burns), Splinting, Logistics).

The PCC guidelines prepare the Service Member for "what to consider next" after all TCCC interventions have been effectively performed and should only be trained after having mastering the principles and techniques of TCCC.

The guidelines are a consolidated list of casualty-centric knowledge, skills, abilities, and best practices are the proposed standard of care for developing and sustaining DoD programs

required to enhance confidence, interoperability, and common trust among all PCC-adept personnel across the Joint force.

The JTS CPGs are foundational to the PCC guidelines and will be referenced throughout this document in an effort to keep these guidelines concise. General information on the Joint Trauma System is available on the JTS website (https://jts.health.mil/) and links to all of the CPGs are also available by using the following link: https://jts.health.mil/index.cfm/PI_CPGs/cpgs.

The TCCC guidelines are included in these guidelines as an attachment because they are foundational AND prerequisite to effective PCC. Remember, the primary goal in PCC is to get out of PCC!!!

PCC Principles

The principles and strategies of providing effective prolonged casualty care are meant to help organize the overwhelming amount of critical information into a clear clinical picture and proactive plan regardless of the nature of injury or illness. The following steps can be implemented in any austere environment from dispersed small team operations in permissive environments to large scale combat operations to make the care of a critically ill patient more efficient for the medic and their team. These mimic the systems and processes in typical intensive care units without relying on technology while leaving the ability to add technological adjuncts as they become available. The following checklist is meant to emphasize some of the most important principles in efficient care of the critically ill patient.

Figure 1. Steps of PCC Principles

1.1. Address and reassess all immediate life threats and interventions per current CoTCCC guidelines before moving onto prolonged casualty care (PCC) considerations.
1.2. Re-triage as required if caring for multiple patients using appropriate triage decision tool.
1.3. Confirm that notifications of the incident and requests for evacuation have been sent and received through the proper channels. This must be evaluated no later than the "C-Communications" in MARC³H³PAWS
1.4. When in doubt refer back to the initial assessment and treatments per current TCCC guidelines

1. **Perform initial lifesaving care using TCCC guidelines and continue resuscitation.**
   The foundation of good PCC is mastery of TCCC and a strong foundation in clinical medicine.
2. **Delineate roles and responsibilities, including naming a team leader.**
   A leader should be appointed who will manage the larger clinical picture while assistants focus on attention intensive tasks.
3. **Perform comprehensive physical exam and detailed history with problem list and care plan.**
   After initial care and stabilization of a trauma or medical patient, a detailed physical exam and history should be performed for the purpose of completing a comprehensive problem list and corresponding care plan.
4. **Record and trend vital signs.**
   Vital signs trending should be done with the earliest set of vital signs taken and continued at regular intervals so that the baseline values can be compared to present reality on a dedicated trending chart.
5. **Perform a teleconsultation.**
   As soon as is feasible, the medic should prepare a teleconsultation by either filling out a preformatted script or by writing down their concerns along with the latest patient information.
6. **Create a nursing care plan.**
   Nursing care and environmental considerations should be addressed early to limit any provider-induced iatrogenic injury.
7. **Implement team wake, rest, chow plan.**
   The medic and each of their first responders should make all efforts to take care of each other by insisting on short breaks for rest, food, and mental decompression.
8. Anticipate resupply and electrical issues
9. **Perform periodic mini rounds assessments.**
   Stepping back from the immediate care of the patient periodically and re-engaging with a mini patient round and review of systems can allow the medic to recognize changes in the condition of the patient and reprioritize interventions.
   - Is the patient stable or unstable?
   - Is the patient sick or not sick?
   - Is the patient getting better or getting worse?
   - How is this assessment different from the last assessment?
10. **Obtain and interpret lab studies.**
    When available, labs may be used to augment these trends and physical exam findings to confirm or rule out probable diagnoses.
11. **Perform necessary surgical procedures.**
    The decision to perform invasive and surgical interventions should consider both risks and benefit to the patient's overall outcome and not merely the immediate goal.
12. **Prepare for transportation or evacuation care.**
    If the medic is caring for the patient over a long tactical move or strategic evacuation, they should be prepared with ample drugs, fluids, supplies and be ready for all contingencies in flight.

13. **Prepare documentation for patient handover.**
    The preparation for transportation and evacuation care should begin immediately upon assuming care for the patient and should include hasty and detailed evacuation requests up both the medical and operational channels with the goal of getting the patient to the proper role of care as soon as possible.

Guideline User Notes

PCC operational context uses the following paradigm for phases of care for different periods of time one is in a PCC scenario:

Table 1. Roles of Care

Role	Definition	Time Period
1a	Carried/Point of Need/Ruck	<1 Hour
1b	Mission-specific transportation platform/Truck	1-4 Hours
1c	Mission support site/House	>4 Hours
1d	Evacuation platform/Plane (as planned or available)	No Timeframe

Where appropriate, a minimum-better-best format is included for situations in which the operational reality precludes optimal care for a given scenario:

- **Minimum**: This is the minimum level of care which should be delivered for a specified level of capability
- **Better**: When available or practical, this includes treatment strategies or adjuncts that improve outcomes while still not considered the standard of care.
- **Best**: This is the optimal medical for a given scenario based on the level of medical expertise of the provider

Expectations of prehospital care, based on TCCC's role-based standard of care, are included within each section:

- **Tier 1**: This is the basic medical knowledge for all service-members.
- **Tier 2**: Those who have been through approved CLS training are expected to be able to meet the standards at this level of care.
- **Tier 3** (Combat Medics/Corpsmen [CMC]): Those who are trained medics/corpsmen are expected to meet the medical standards for this tier.
- **Tier 4** (Combat Paramedic/Provider [CPP]): This is the highest level of prehospital capability and will have a significantly expanded scope of practice.

MASCAL/TRIAGE - PCC

Background

The foundation of effective PCC is accurate triage for both treatment in the PCC setting and for transportation to a higher level of care, as well as effective resource management across the entire trauma system. Resource management includes the appropriate utilization of medical and non-medical personnel, equipment and supplies, communications, and evacuation platforms. Like most Mass Casualty incidents (MASCAL), the purpose of triage in a PCC setting is to swiftly identify casualty needs for optimal resource allocation in order to improve patient outcomes. However, PCC presents unique and dynamic triage challenges while managing casualties over a prolonged period with a low likelihood of receiving additional medical supplies or personnel with enhanced medical capabilities apart from pre-established networks. MASCAL in a PCC environment will necessitate more conservative resource allocation than traditional MASCAL in mature theaters or fixed medical facilities where damage control surgery, intensive care, and medical logistical support are more readily available, and resupply is more likely. PCC dictates the need for implementing various triage and resource management techniques to ensure the greatest good for all. The objectives and basic strategies are the same for all MASCAL; however, tactics will vary depending on the available resources and situations.

MASCAL Decision Points

1. Determine if a PCC MASCAL is occurring – do the requirements for care exceed capabilities?
    - What is the threat? Has it been neutralized or contained? If not, security takes priority.
    - What is the total casualty estimate?
    - Are there resource limitations that will affect survival?
    - Can medical personnel arrive at the casualty location, or can the casualty move to them?
    - Is evacuation possible?
    - Communicate the situation to all available personnel conducting or enabling PCC.
    - Assess requirements for which class of triage you are facing (see Appendix C) and scale medical action to maximize lethality then survivability.
    - Remain agile and be ready to move based on the mission.
2. Determine if conditions require significant changes in the commonly understood and accepted standards of care (Crisis Standards of Care)[3] or if personnel who are not ordinarily qualified for a particular medical skill will need to deliver care. MASCAL in PCC requires both medical and non-medical responders initially save lives and preserve survivable casualties. Both groups will need skills traditionally outside existing paradigms, such as non-medical personnel taking and record vital signs or Tier 3 TCCC medical personnel maintaining vent settings on a stable patient. The MASCAL standard of care will be driven by the volume of casualties, resources, and risk or mortality/morbidity due to degree of injury/illness; as such, remain agile throughout the MASCAL and trend in both directions based upon resources available.
3. MASCAL management is often intuitive and reactive (due to lack of full mission training opportunities) and should rely on familiar terminology and principles. Treatment and casualty movement should be rehearsed to create automatic responses.

4. The tactical and strategic operational context will underpin every facet of MASCAL in a PCC environment, operational commanders MUST be involved in every stage of MASCAL response (The mere fact that a medical professional or team of medical professionals is forced to hold a casualty longer than doctrinal planning timelines means there is a failure in the operational/logistical evacuation chain. Battle lines, ground-to-air threat, etc. levels may have shifted.)
5. Logistical resupply may need to include non-standard means and involve personnel and departments not typically associated with Class VIII in other situations (i.e. aerial resupply, speedballs, caches, local national market procurement).
6. The most experienced person should establish MASCAL roles and responsibilities, as appropriate.

Key Considerations in MASCAL

- Usually, simpler is better.
- Focus on those that will preserve scarce resources, such as blood.
- Triage is a continuous process and should be repeated as often as is clinically and operationally practical.
- Avoid high resource and low yield interventions.
- Emergency airway interventions should prioritize REVERSIBLE pathology in salvageable patients.
- Decisions will depend on available resources and skillsets (i.e. penetrating traumatic brain injury [TBI] triaged differently if no neurosurgery is available in a timely manner or at all in theater).
- Conserve, ration, and redistribute additional scarce resources (i.e. blood, drug).

MASSIVE HEMORRHAGE - PCC

Background

Early recognition and intervention for life-threatening hemorrhage are essential for survival. The immediate priorities are to control life-threatening hemorrhage and maintain vital organ perfusion with rapid blood transfusion.[4]

Pre-deployment, Mission Planning, and Training Considerations

1. Conduct unit level blood donor testing (for blood typing, transfusion transmitted diseases and Low Titer blood type O titers) and develop operational roster.
2. Define Cold Chain Stored Whole Blood (CSWB) distribution quantities in area of responsibility.
3. Manage and equip prehospital blood storage program if unit policies and procedures allow for prehospital blood storage.

Table 2. PCC Role-Based Guidelines for Massive Hemorrhage Management

PCC Role-based Guidelines for Massive Hemorrhage Management				
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	**** All Personnel - Complete Basic TCCC Management Plan for Massive Hemorrhage then:*** ▪ Identify life-threatening bleeding that may have started or was not adequately controlled with initial interventions in TCCC Basic Management Plan for Massive Hemorrhage. ▪ Check tourniquets to ensure that they have not shifted or loosened.
				▪ Re-assess and re-apply MARCH interventions. ▪ Perform all recommended interventions from guidelines for above tier level.
				▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Role 1a** ▪ Conduct Triage – Time Assessment. ▪ Assess extremities distal to pressure dressings to ensure that they are not acting as a venous tourniquet which could result in compartment syndrome by checking pulses and the skin color distal to the dressing. ▪ Communicate evacuation and re-supply requirements (i.e. Blood resupply/Speedball). ▪ Administer Calcium and Tranexamic Acid (TXA) per TCCC guideline.
				Role 1b ▪ Re-assess and re-apply MARCH interventions. ▪ Consider tourniquet conversion (> 2 hours but before 6 hours). ▪ Assess for refractory shock – see Circulation Section.
				Role 1c ▪ Evaluate for compartment syndrome. ▪ Consider teleconsultation. ▪ Continue resuscitation until: min: palpable radial pulse or improved mental status better: SBP > 90 mmHg best: SBP between 100-110 mmHg. Discontinue fluid administration when one of the above end points have been achieved.

	▪ Ensure interventions noted above are completed by TCCC ASM, CLS and Combat Medic/Corpsmen (CMC) personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include:
	Role 1a Re-assess all prior MARCH interventions.
	Role 1b ▪ Assess using ultrasound (if available) including Extended Focused Assessment with Sonography in Trauma, Central Venous Pressure. ▪ Determine hypovolemia vs. refractory shock to drive decision on further resource utilization.
	Role 1c ▪ Convert to type-specific blood replacement, if testing available. ▪ Establish Foley catheter with goal Urine Output (UOP) of > ½ ml/kg per hour.

Link to Damage Control Resuscitation (DCR) in Prolonged Field Care CPG, 01 Oct 2018 [5]

AIRWAY MANAGEMENT - PCC

Background

Airway compromise is the second leading cause of potentially survivable death on the battlefield after hemorrhage.[6] Complete airway occlusion can cause death from suffocation within minutes. Austere environments present significant challenges with airway management. Limited provider experience and skill, equipment, resources, and medications shape the best management techniques. Considerations include: limited availability of supplemental oxygen; medications for induction/rapid sequence intubation, paralysis, and post-intubation management; and limitations in available equipment. Another reality is limitations in sustainment training options, especially for advanced airway techniques. Due to these challenges, some common recommendations that may be considered "rescue" techniques in standard hospital airway management may be recommended earlier or in a non-standard fashion to establish and control an airway in a PCC environment. Patients who require advanced airway placement tend to undergo more interventions, be more critically injured, and ultimately have a higher proportion of deaths. The ability to rapidly and consistently manage an airway when indicated, or spend time on other resuscitative needs when airway management is not indicated, may contribute to improved outcomes.[7,8]

Table 3. PCC Role-based Guidelines for Airway Management

PCC Role-based Guidelines for Airway Management				
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	**** All Personnel - Complete Basic TCCC Management Plan for Airway then:*** Assess for airway problem; use patient positioning per TCCC guidelines to maintain open airway.
				▪ Re-assess airway interventions performed in TCCC. ▪ Positive end-expiratory pressure (PEEP) valves should be used anytime you are using a bag valve mask. ▪ Use nasal pharyngeal airway (NPA). ▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Role 1a** ▪ Airway adjuncts should be assessed for efficacy by checking the patient's work of breathing, end-tidal CO2 (ETCO2) and pulse oximetry levels. ▪ Level of sedation should be continuously assessed every 5 minutes for patients sedated deep enough for endotracheal intubation.
				Role 1b ▪ Re-asses airway before, after and during any patient movement. ▪ Airway adjuncts with an inflatable cuff such as ET or cricothyrotomy tube or inflatable laryngeal mask airways (LMA) should be assessed for proper inflation levels to ensure that they are not under or over inflated. ▪ Inflate the cuff with a 10cc syringe and then releasing your thumb from the plunger to let the plunger equalize.

		Role 1c ▪ Airway adjuncts with an inflatable cuff such as ET or cricothyrotomy tube or inflatable LMA should be assessed for proper inflation levels to ensure that they are not under or over inflated. ▪ Mechanical suction device and yankauer suction for suctioning out the oropharynx. ▪ Airway adjuncts should be assessed for efficacy by checking the patient's work of breathing, ETCO2 and pulse oximetry levels. ▪ Mouth care should be performed per the attached nursing care checklist in appendix.
	▪ Ensure above interventions are completed by TCCC ASM, CLS and CMC personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Role 1a** Re-assess all prior MARCH interventions.	
		Role 1b ▪ Re-assess cuff pressures per above. ▪ Continued assessment of patient's work of breathing, ETCO2 and pulse oximetry levels.
		Role 1c ▪ Inflate and periodically check cuff pressures with a cuff manometer to a goal of 20 mmHg. ▪ Use heat moisture exchanger to keep contaminants out and endogenous heat and moisture in the lungs. ▪ Inline suction catheter for suctioning airway adjunct as indicated.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

Link to Airway Management in Prolonged Field Care, 01 May 2020 [9]

RESPIRATION AND VENTILATION - PCC

Background

Respiration is the process of gas exchange at the cellular level. Oxygen is conducted into the lung and taken up by the blood via hemoglobin to be transported throughout the body. In the peripheral tissues, carbon dioxide is exchanged for oxygen, which is transported by the blood to the lungs, where it is exhaled. This process is essential to cellular and organism survival. Dysfunction of this process is a feature of multiple-injury patterns that can lead to increased morbidity and mortality.

Table 4. PCC Role-based Guidelines for Respiration Management

PCC Role-based Guidelines for Respiration Management	

TCCC-ASM, TCCC-CLS, TCCC-CMC, TCCC-CPP	**** All Personnel - Complete Basic TCCC Management Plan for Respiration then:***
	▪ Identify Respiratory distress.
	▪ Some Level 1 providers may be trained in Basic Life Support (BLS), and if so, may offer the following interventions:
	  ▪ Open the airway using Head Tilt or Jaw Thrust maneuver.
	  ▪ Provide rescue breaths per BLS.

TCCC-CLS, TCCC-CMC, TCCC-CPP	▪ Perform all recommended interventions from guidelines for above Tier level
	▪ Additional interventions include:
	  ▪ Use Bag Valve Mask with PEEP Valve.
	  ▪ Use NPA.

TCCC-CMC, TCCC-CPP	▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel.
	▪ Conduct inventory of all resources.
	▪ Document all pertinent information on PCC Flowsheet (attached).
	▪ Additional interventions include:
	  ▪ Target ventilation to pulse oximetry level of 92%; use supplemental oxygen if available.
	  ▪ Use end-tidal carbon dioxide monitor and maintain ETCO2 between 35-45 mmHg.
	  ▪ If definitive airway is required, consider cricothyrotomy tube as less sedation and pain management is required to facilitate a patent and secure method for respirations.

TCCC-CPP	▪ Ensure interventions noted above are completed by TCCC ASM, CLS, and CMC personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Mechanical Ventilation (For trained providers)** ▪ Use of mechanical ventilators in the PCC environment requires experience and training, best accomplished under board-certified medical personnel and sustained routinely. ▪ Ensure appropriate amount of induction, sedation, and pain management to sustain the patient for up to 96 hours in a PCC environment.
	Role 1a ▪ BVM, NPA, Pulse oximetry to maintain >92%. ▪ Intubate if no gag reflex and casualty is salvageable (TBI).
	Role 1b Add ETCO2 monitoring, goal 35-45 mmHg; initiate mechanical ventilation.
	Role 1c ▪ Establish sedation, pain management maintenance plan for >96 hours; use non-invasive ventilation as able. ▪ Monitor ABGs.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

Additional Considerations

- When in a PCC environment, simple monitoring technologies are able to be used by most providers in each of the provider categories to ensure adequate gas exchange and oxygen delivery. Peripheral oxygen saturation can be measured using a pulse oximeter which provides a measurement of hemoglobin saturation and, by inference, the effectiveness of measures to oxygenate a patient. Ventilation can be monitored with end-tidal carbon dioxide. The use of these tools together in a PCC environment provides estimates of oxygen transport to the cells, tissue metabolism, and adequacy of ventilation.
- Providers in the PCC environment can adopt, implement, monitor, and sustain respiration using concepts of manipulating minute ventilation (respiratory rate multiplied by tidal volume). Put simply, it is the number of times a patient is breathing each minute multiplied by the amount of air breathed in with each breath.
- Support of adequate minute ventilation can be performed in an escalating algorithm with rescue breathing, bag valve mask assisted ventilation, and mechanical ventilation. Each of these methods may require escalation of airway management skills and respiratory skills. Manipulation of any of the variables of minute ventilation will alter gas exchange. Therefore, medical providers in the PCC environment at all levels will need to be competent with the monitoring devices appropriate to their level of training. At a minimum, all providers with specific medical training should be competent to use and interpret the previous paragraph's monitoring devices.
- The causes of respiratory failure can overlap and become confusing. When in doubt and whenever possible, initiate a Telemedicine Consultation for further guidance and input.

CIRCULATION AND RESUSCITATION - PCC

Background

PCC presents a unique challenge for implementing damage control resuscitation (DCR) as defined by the JTS guideline. PCC goes beyond DCR and should bridge the gap between the prevention of death, the preservation of life, and definitive care. The goals are a return to a normal level of consciousness (LOC), increase and stabilization of systolic blood pressure at 100 - 110 mm Hg when appropriate, and stabilization of vital signs – Heart rate, respiratory rate, oxygen saturation, etc.

Table 5. PCC Level for Circulation and Resuscitation

<table>
<tr><th colspan="5">PCC Level for Circulation and Resuscitation</th></tr>
<tr><td rowspan="5">TCCC-ASM</td><td rowspan="4">TCCC-CLS</td><td rowspan="3">TCCC-CMC</td><td rowspan="3">TCCC-CPP</td><td>* All Personnel - Complete Basic TCCC Management Plan for Massive Hemorrhage then:
Role 1a
▪ Re-assess all tourniquets and wound dressings.
▪ Ensure that bleeding has stopped.
▪ If bleeding persists, consider additional tightening of the tourniquet, the use of an additional tourniquet, or the use of hemostatic dressings with wound packing to stem the hemorrhage.
▪ Conduct the principles of wound care to avoid infection and possible follow-on sepsis.
▪ Initiate hypothermia prevention measures.</td></tr>
<tr><td>Role 1b/1c
▪ Continue and/or initiate above circulation interventions.
▪ Initiate hypothermia prevention measures, if not already completed.</td></tr>
<tr><td>▪ Perform all recommended interventions from guidelines for above Tier level.
▪ Additional interventions include:
Role 1a
▪ Re-assess all tourniquets and wound dressings.
▪ Ensure that bleeding has stopped.
▪ If bleeding persists, consider additional tightening of the tourniquet, the use of an additional tourniquet or the use of hemostatic dressings with wound packing to stem the hemorrhage.
▪ Replace any limb tourniquet placed proximal over the uniform with one applied directly to the skin 2-3 inches above the wound.
▪ Assess extremities distal to pressure dressings.
▪ Check pulses and the skin color distal to the dressing.
▪ Decreased pulses or skin mottling may indicate the dressing is acting as a venous tourniquet.
▪ If present, dressing may need to be replaced or readjusted.
▪ Ongoing venous tourniquet could result in limb damage or development of compartment syndrome.
▪ Conduct the principles of wound care to avoid infection and possible follow-on sepsis.
▪ Initiate hypothermia prevention measures.</td></tr>
<tr><td>Role 1b/1c
▪ Continue and/or initiate above circulation interventions.
▪ Initiate hypothermia prevention measures, if not already completed.</td></tr>
<tr><td colspan="2">▪ Re-assess and re-apply MARCH interventions.
▪ Review transfusion transmitted disease (TTD)/titer of present unit members.
▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel</td></tr>
</table>

PCC Level for Circulation and Resuscitation

- Conduct inventory of all shock treatment supplies including whole blood, testing equipment, IVs, and other resources.
- Document all pertinent information on PCC Flowsheet (attached).
- Additional interventions include:

Role 1a

- Re-assess tourniquets and wound dressings as noted in above tier recommendations.
- Convert tourniquets per TCCC guidelines.
  - In less than 2 hours if bleeding can be controlled with other means.
  - DO NOT remove a tourniquet that has been in place more than 6 hours.
- Initiate hypothermia prevention measures.
- If present, assess pelvic compression device and verify placement and tightness.
- IV or intraosseous (IO) access if not already initiated in MARCH interventions:
  - If the casualty remains in hemorrhagic shock or at significant risk of shock.
  - If the casualty needs medications, but cannot take them by mouth.
- Initiate resuscitation with fluid replacement:
  - For casualties in hemorrhagic shock.
  - Give blood products per DCoT and TCCC guidelines.
  - Give calcium per TCCC guidelines.
  - If not already done, give TXA per TCCC guidelines.
  - Re-assess the casualty after each unit of blood and note on PCC FC vitals tracker.
- The goals of resuscitation:
  - Return to a normal LOC.
  - Return of palpable radial pulse
  - Continue resuscitation until:
    - **Minimum**: palpable radial pulse or improved mental status
    - **Better**: SBP > 90 mmHg
    - **Best**: SBP between 100-110 mmHg.
  - Stabilization of vital signs – Heart rate, respiratory rate, oxygen saturation.
- If the patient has signs of ongoing shock despite hemorrhage control:
  - Re-assess look for bleeding!
  - Consider alternate causes of shock – hypovolemic (burn, sepsis, diarrheal illness and other causes of non-hemorrhagic shock), obstructive (tension pneumothorax or cardiac tamponade), distributive (spinal cord injury, sepsis, anaphylaxis, etc.).
  - If shock is not hemorrhagic, then treat for alternate cause of shock: judicious crystalloid for sepsis and burns, chest tube for tension pneumothorax; crystalloid and vasopressors* for evidence of spinal cord injury with neurogenic shock.
- If resuscitation goals can all be met, maintain crystalloid IV or discontinue IV/IO resuscitation and have the casualty orally rehydrate (avoid free water due to risk of hyponatremia) until 0.3 – 0.5 mL/kg/hr. UOP is achieved.
- Initiate hypothermia prevention measures.
- Differentiate between transient responder, non-responder, and refractory shock.
- Communicate evacuation and re-supply requirements (i.e. blood resupply/speedball).

PCC Level for Circulation and Resuscitation	
Roles 1b/1c	▪ Continue and/or initiate above circulation and resuscitation interventions. ▪ Manage IV or IO access for ongoing resuscitation. ▪ Initiate hypothermia prevention measures. ▪ Differentiate between transient responder, non-responder, and refractory shock. ▪ Communicate evacuation and re-supply requirements (i.e. blood resupply/speedball). ▪ Initiate teleconsultation to medical control.
	▪ Re-assess and re-apply MARCH interventions. ▪ Review TTD/titer of present unit members. ▪ Ensure all interventions noted above are completed by TCCC ASM, CLS and CMC personnel ▪ Conduct inventory of all shock treatment supplies including whole blood, testing equipment, IVs, and other resources etc. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Role 1a** Interventions for both Tier 3 and Tier 4 level providers at this phase are the same.
Role 1b	▪ Ultrasound may be used to further refine the cause of ongoing hemorrhage or other causes of shock if available and medical provider is trained in its use. ▪ If ultrasound is available, teleconsultation can also be used to guide the provider in its implementation. ▪ Continually observe for changes in patient status, signs of clinical deterioration, alternate causes of shock, and need for change in resuscitation strategies. ▪ Continue resuscitation until: ・ **Minimum**: palpable radial pulse or improved mental status ・ **Better**: SBP > 90 mmHg ・ **Best**: SBP between 100-110 mmHg.
Role 1c	▪ Convert to type-specific blood replacement. ▪ Ultrasound may be used to further refine the cause of ongoing hemorrhage or other causes of shock if available and medical provider is trained in its use. ▪ If ultrasound is available, teleconsultation can also be used to guide the provider in its implementation. ▪ Continually observe for changes in patient status, signs of clinical deterioration, alternate causes of shock and need for change in resuscitation strategies. ▪ Continue resuscitation until: ・ **Minimum**: palpable radial pulse or improved mental status ・ **Better**: SBP > 90 mmHg ・ **Best**: SBP between 100-110 mmHg. ▪ If SBP remains less than 100-110 mmHg despite appropriate resuscitation and hemorrhage control, a vasopressor agent should be started if available*.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

** All use of pressors should be administered by role-based approved protocols or teleconsultation approval:*

- *norepinephrine continuous infusion 0.1–0.4 mcg/kg/min*
- *vasopressin continuous infusion 0.01-0.04 units*

COMMUNICATION AND DOCUMENTATION - PCC

Background

Communication and documentation in PCC are linked priorities as they are activities that are synergistic. For instance, the standard documentation forms (see below) that are used to track the important medical interventions and trends are the recommended scripts that are used in a teleconsultation. Effective documentation leads to effective communication, both in the immediate PCC environment and as a long-term medical management tool for the casualty.

Communication

- Communicate with the casualty if possible. Encourage, reassure, and explain care.
- Communicate with tactical leadership as soon as possible and throughout casualty treatment as needed. Provide leadership with casualty status and evacuation requirements to assist with coordination of evacuation assets.
- Verify evacuation request has been transmitted and establish communication with the evacuation platform as soon as tactically feasible relaying: mechanism of injury, injuries sustained, signs/symptoms, treatments rendered, and other information as appropriate. Have a rehearsed script to relay vital information to the next echelon of care prioritize interventions that cannot be seen by the next provider, such as medications.
- Ensure appropriate notification up the chain of command that PCC is being conducted; requesting support based on the MASCAL decision points.
- Call for teleconsultation as early and as often as needed (e.g., higher medical capability in the Chain of Command, the Advanced VIrtual Support for OpeRational Forces system line, etc.).
- Remember, communication of the situation and medical interventions that have been done and are ongoing includes both teleconsultation and the “handoff report.”

Documentation of Care

- There are 3 levels of documentation, categorized in a minimum, better, best format:
  - Minimum - Documentation of care on the TCCC card (DD1380).
  - Better - Utilization of a standard PCC flowsheet (if available), example attached.
  - Best - Completion of a formal After Action Report (AAR) after patient handoff.
- Transfer documented clinical assessments and treatments rendered. If the availably to scan and/or transmit this information to all parties involved teleconsultation (using all approved and available means), do so for them to have as much of the information as possible.
- Perform a detailed head-to-toe assessment and record all findings as a problem list so that a comprehensive care plan can then be constructed using the attached flow sheet.

Table 6. PCC Role-based Guidelines for Communications and Documentation

PCC Role-based Guidelines for Communication and Documentation				
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	*Complete Basic TCCC Communication and Documentation Principles then:* ▪ Identify requirements for communicating care to the casualty, leadership, and medical personnel in accordance with TCCC Guidelines. ▪ Document casualty information on the DD Form 1380 TCCC Card and ensure proper placement of that card on the casualty, in accordance with DHA-PI 6040.01. ▪ Initiate scripted teleconsultation.
				▪ Monitor the documentation for each casualty and ensure that it is completed by those service members assisting with care. ▪ Initiate scripted teleconsultation.
				Ensure documentation and communication is completed for each casualty in accordance with PCC standards: ▪ Ensure that communication is established with evacuation assets and/or receiving facilities. ▪ Prepare evacuation request and set up priorities for evacuation for each casualty. ▪ Ensure DD1380 TCCC Cards are completed for every casualty. ▪ Initiate scripted teleconsultation. ▪ Complete AAR.
				Ensure documentation and communication is completed for each casualty in accordance with PCC standards: ▪ Ensure communication is established with evacuation assets and/or receiving facilities. ▪ Initiate scripted teleconsultation, if needed. ▪ Prepare evacuation request and set up priorities for evacuation for each casualty. ▪ Ensure DD1380 TCCC Cards are completed for every casualty. ▪ Complete After Action Report with an emphasis on the scenario's impact on future unit-level medical training and logistics requirements.

* Link to Documentation Requirements for Combat Casualty Care, 18 Sep 2020 CPG [11]

HYPOTHERMIA - PCC

Background

Prevention of hypothermia must be emphasized in combat operations and casualty management at all levels of care. Hypothermia occurs regardless of the ambient temperature; hypothermia can, and does, occur in both hot and cold climates. Because of the difficulty, time, and energy required to actively re-warm casualties, significant attention must be paid to preventing hypothermia from occurring in the first place. Prevention of hypothermia is much easier than treatment of hypothermia; therefore prevention of heat loss should start as soon as possible after the injury. This is optimally accomplished in a layered fashion with rugged, lightweight, durable products that are located as close as possible to the point of injury, and then utilized at all subsequent levels of care, including ground and air evacuation, through all levels of care.[12]

Table 7. PCC Role-based Guidance for Hypothermia Management

PCC Role-based Guidance for Hypothermia Management					
TCCC-ASM	**TCCC-CLS**	**TCCC-CMC**	**TCCC-CPP**		
				Complete Basic TCCC Management Plan for Hypothermia then:	
				Role 1a	▪ Take early and aggressive steps to prevent further body heat loss and add external heat when possible for both trauma and severely burned casualties. ▪ Minimize casualty's exposure to cold ground, wind and air temperatures. Place insulation material between the casualty and any cold surface as soon as possible. ▪ Keep protective gear on or with the casualty, if feasible. ▪ Replace wet clothing with dry clothing, if possible, and protect from further heat loss. If unable to replace the dry clothing, wrap an impermeable layer around the casualty. ▪ Place an active heating blanket on the casualty's anterior torso and under the arms in the axillae. ▪ **Caution**: DO NOT place any active external heating directly on the skin or in areas of skin which are under pressure or have poor blood flow as this increases risk of injury and/or skin burns. ▪ Enclose the casualty with the exterior impermeable enclosure bag, if available. ▪ Protect the casualty from exposure to wind and precipitation on any evacuation platform.
				Role 1b	▪ Continue and/or initiate above hypothermia interventions. ▪ Pre-stage an insulated hypothermia enclosure system with external active heating for transition from the non-insulated hypothermia enclosure systems; seek to improve upon existing enclosure system when possible. ▪ Upgrade hypothermia enclosure system to a well-insulated enclosure system using a hooded sleeping bag or other readily available insulation inside the enclosure bag/external vapor barrier shell. ▪ **Best**: Improvised hypothermia wrap with high-quality insulation with cold-rated sleeping bag combined with heat source, internal vapor barrier, outer impermeable enclosure. ▪ When using the Hypothermia Prevention and Management Kit (HPMK) ready-heat-blanket, perform frequent skin checks to monitor for contact burns. ▪ Protect the casualty from exposure to wind and precipitation on any evacuation platform.

PCC Role-based Guidance for Hypothermia Management
Role 1c ▪ Continue and/or initiate the Role 1a/Role 1b phases as detailed above. ▪ Replace ready-heat-blanket when using >10 hours.
▪ Perform all recommended interventions from guidelines for above Tier level ▪ Additional interventions include: **Role 1a** Communicate re-supply requirements.
Role 1b Protect the casualty from exposure to wind and precipitation on any evacuation platform.
Role 1c ▪ Continue and/or initiate the Role 1a/Role 1b phases as detailed above ▪ Replace ready-heat-blanket when using >10 hours.
▪ Interventions for both CMC and CPP are the same. ▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include: **Role 1a** ▪ Use a battery-powered warming device to deliver IV resuscitation fluids, in accordance with current TCCC guidelines, at flow rate up to 150 ml/min with a 38°C output temperature. ▪ Communicate re-supply requirements.
Role 1b ▪ Convert to continuous temperature monitoring. ▪ **Minimum**: Scheduled temperature measurement with vital sign evaluations. ▪ **Better**: Continuous forehead dot monitoring. ▪ **Best**: Continuous core temperature monitoring. ▪ Protect the casualty from exposure to wind and precipitation on any evacuation platform.
Role 1c ▪ Continue and/or initiate the Role 1a/Role 1b phases as detailed above. ▪ Replace ready-heat-blanket when using >10 hours.
Interventions for both CMC and CPP are the same.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

*Link to Hypothermia Prevention, Monitoring and Management, 18 Sep 2012 CPG [12]

HYPERTHERMIA - PCC

Background

1. Hyperpyrexia is elevated body temperature.
2. Fever is elevated body temperature in response to a change in hypothalamic set point (infections).
3. Hyperthermia is elevated body temperature without a change in hypothalamic set point (heat illness, hyperthyroid, drugs).
4. The Second Law of Thermodynamics states that heat flows from hot to cold.
5. Heat transfer can occur through several processes:
    a. Radiation
    b. Conduction
    c. Convection
    d. Evaporation

Heat exhaustion

Symptoms: weak, dizzy, nauseated, headache, sweating, normal mental status. Heat exhaustion requires replacement of fluids and electrolytes.

Heat stroke

Symptoms: Hyperthermia + mental status changes. Heat stroke requires immediate cooling.

Table 8. PCC Role-based Guideline for Hyperthermia Management

PCC Role-based Guidance for Hyperthermia Management				
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	***Complete Basic TCCC Management Plan for Hyperthermia then:***
				Role 1a ▪ Move the casualty to the shade if possible. ▪ Insulate the casualty from the ground (conduction). ▪ Remove the casualty from a vehicle (radiation). ▪ If situation allows, remove the casualty's helmet and vest (evaporation). ▪ Fan the casualty (convection). ▪ If the casualty is conscious and not vomiting, give liquids. ▪ Protect the casualty from exposure to sources of heat if possible. ▪ DO NOT give acetaminophen, aspirin or ibuprofen for hyperthermia, only for fever. ▪ Prevent heat illness/injury in casualties by maintaining hydration, adding salt to food, resting in shade, staying off hot surfaces (ground or vehicle), removing tactical gear when possible.
				Role 1b Continue and/or initiate above hyperthermia interventions.
				Role 1c Continue and/or initiate the Role 1a/Role 1b phases as detailed above.
				▪ Perform all recommended interventions from guidelines for above tier level ▪ Additional interventions include:

PCC Role-based Guidance for Hyperthermia Management	
Role 1a	▪ If the casualty is unconscious or vomiting, use IV/IO fluids. ▪ Communicate re-supply requirements.
Role 1b	Continue and/or initiate above hyperthermia interventions.
Role 1c	Continue and/or initiate the Role 1a/Role 1b phases as detailed above.
	▪ Interventions for both CMC and CPP providers are the same. ▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include:

Role 1a	▪ If the casualty is unconscious or vomiting, use IV/IO fluids.
	▪ Monitor for signs and symptoms of heat exhaustion - if present: Immediately replace fluids and electrolytes.
	▪ Monitor for signs and symptoms of heat stroke - if present:
	  ▪ Immediate cooling must be initiated.
	  ▪ **Minimum**: Wetting clothing.
	  ▪ **Better**: Fanning the casualty after wetting clothing.
	  ▪ **Best**: Immersion in water.
	▪ Casualties should eat, if possible, to prevent sodium loss, which may lead to dilutional hyponatremia (low sodium).
	▪ Dilutional hyponatremia may look like heat illness, but is due to drinking and not eating.
	▪ Seizures should be treated with benzodiazepines.
	▪ Communicate re-supply requirements.

Role 1b	▪ Convert to continuous temperature monitoring.
	  ▪ **Minimum**: Scheduled temperature measurement with vital sign evaluations.
	  ▪ **Better**: Continuous forehead dot monitoring.
	  ▪ **Best**: Continuous core temperature monitoring.
	▪ Prevent heat illness/injury in casualties by maintaining hydration, adding salt to food, resting in shade, staying off hot surfaces (ground or vehicle), removing tactical gear when possible.

Role 1c	▪ Continue and/or initiate the Role 1a/Role 1b phases as detailed above.
	Interventions for both CMC and CPP are the same.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

HEAD INJURY/TBI - PCC

Background

TBI occurs when external mechanical forces impact the head and cause an acceleration/deceleration of the brain within the cranial vault which results in injury to brain tissue. TBI may be closed (blunt or blast trauma) or open (penetrating trauma).[13] Signs and symptoms of TBI are highly variable and depend on the specific areas of the brain affected and the injury severity. Alteration in consciousness and focal neurologic deficits are common. Various forms of intracranial hemorrhage, such as epidural hematoma, subdural hematoma, subarachnoid hemorrhage, and hemorrhagic contusion can be components of TBI. The vast majority of TBIs are categorized as mild and are not considered life threatening; however, it is important to recognize this injury because if a patient is exposed to a second head injury while still recovering from a mild TBI, they are at risk for increased long-term cognitive effects. Moderate and severe TBIs are life-threatening injuries.

Pre-deployment, Mission Planning, and Training Considerations

1. Conduct unit level TTD/Titer testing and develop an operational roster.
2. Conduct baseline neurocognitive assessment per Service guideline.
3. When possible and practical, keep patient in an elevated orientation to approximately 30 degrees while maintaining C-spine precautions (as clinically indicated) and airway control (don't just elevate the head by bending the neck).
4. Define CSWB distribution quantities in area of responsibility.
5. Determine feasibility and requirement for pre-deployment unit level blood draw.
6. Conduct unit level pre-deployment blood draw as required.
7. Ensure critical head-injury adjunct medications appropriately stocked and storage requirements met.

Treatment Guidelines

Table 9. PCC Role-based Guideline for Head Injury/TBI Management

PCC Role-based Guidance for Head Injury/TBI Management				
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	***Complete Basic TCCC Management Plan for Heat Injury/TBI then:***
				Role 1a ▪ Identification and local wound management of any open head wounds/skull fractures. Priorities should include hemorrhage control, removal of gross contamination, and protection/coverage of any exposed dura or brain matter. ▪ Military Acute Concussive Evaluation 2 (MACE2) (*See Appendix E) examination per DoD/TCCC guideline. ▪ Communicate evacuation requirements (need for TBI evaluation, neurosurgery) ▪ Communicate re-supply requirements.
				Role 1b/1c ▪ Re-assess and re-apply MARCH interventions. ▪ Serial neurologic checks, including pupil exam and identify signs of elevated or rising intracranial pressure (Appendix E) - at least hourly. ▪ Identify catastrophic/non-survivable brain injury. ▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for any patient with initial mild TBI who deteriorates to moderate/severe TBI category.
				▪ Re-assess and re-apply MARCH interventions. ▪ Conduct inventory of all treatment supplies. ▪ Document all pertinent information on PCC Flowsheet (attached).
				Role 1a ▪ Identification and local wound management of open head wounds/skull fractures. Priorities should include hemorrhage control, removal of gross contamination, and protection/coverage of any exposed dura or brain matter. ▪ MACE2 examination per TCCC guideline. ▪ Communicate evacuation requirements (need for TBI evaluation, neurosurgery). ▪ Communicate re-supply requirements.
				Role 1b/1c ▪ Re-assess and re-apply MARCH interventions. ▪ Serial neurologic checks and identify signs of elevated or rising intracranial pressure (Appendix E). ▪ Administer appropriate antibiotics for any open head wounds or skull fracture (see antibiotics section). ▪ Identify the critical observations that should be reported to medical personnel for trauma casualties with a suspected head injury, in accordance with the MACE2. ▪ Teleconsultation with trauma surgeon and/or neurosurgeon as available. ▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for any patient with initial mild TBI who deteriorates to moderate/severe TBI category.
				▪ Re-assess and re-apply MARCH interventions. ▪ Ensure all interventions noted above are completed by non-medical TCCC ASM and CLS personnel and CLS-trained service members. ▪ Conduct inventory of all treatment supplies. ▪ Document all pertinent information on PCC Flowsheet (attached).
				Role 1a ▪ Identification and local wound management of any open head wounds/skull fractures. Priorities should include hemorrhage control, removal of gross contamination, and protection/coverage of any exposed dura or brain matter.

PCC Role-based Guidance for Head Injury/TBI Management	
	▪ Identify signs of elevated or rising intracranial pressure (ICP) per Appendix E. Initiate immediate treatment for signs of elevated ICP including initial bolus of 3% hypertonic saline (HTS) 250-500 ml if available. Alterative: 23.4% sodium chloride. ▪ Administer TXA as single 2gram IV or IO bolus (no second dose required). ▪ Communicate evacuation requirements (need for TBI evaluation, neurosurgery). ▪ Communicate re-supply requirements.

Role 1b	▪ Re-assess and re-apply MARCH interventions.
	▪ Administer appropriate antibiotics for any open head wounds or skull fracture (see antibiotics section).
	▪ Maintain goal SBP >90 mmHg with initial fluid/blood product resuscitation.
	▪ Serial neurologic checks and identify signs of elevated or rising intracranial pressure (Appendix E); If noted, the following interventions are recommended, if possible:
	  ▪ HTS administration (intermittent bolus versus continuous infusion) per Appendix E. Alterative: 23.4% sodium chloride.
	  ▪ Supplemental oxygen to maintain O2 sats > 94% and <99%, ETCO2 if intubated with goal of mild hyperventilation to 35-40.
	  ▪ Brief (less than 30 minutes) moderate hyperventilation to goal pCO2/ETCO2 20-30 may be performed for signs of impending/active herniation (pupil becomes fixed and dilated); if there is a neurosurgical capability.
	  ▪ ** Note: Use hyperventilation only as a temporizing measure while additional ICP treatments are being administered or tactical evacuation is in process.
	▪ Repeat primary and secondary survey for any abrupt decline in the Glasgow Coma Scale (GCS) or change in pupil exam to rule out non-neurologic causes.
	▪ Minimize analgesia and sedation agents, and avoid paralyses, if possible, to preserve ability to obtain neurologic exam, but medical and operational considerations should take priority if deeper sedation or paralysis required.
	▪ Teleconsultation with Trauma Surgeon and/or Neurosurgeon as available.
	▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for any patient with initial mild TBI who deteriorates to moderate/severe TBI category.
	▪ Repeat triage evaluation and identification of likely non-survivable condition (or associated injuries) based on injury types/severity and required vs available resources.

Role 1c	▪ Continue serial neurologic checks including GCS and pupil exam at least hourly. ▪ Immediate seizure treatment with benzodiazepines, consider ketamine for refractory seizures. ▪ Temperature management and aggressive fever control. ▪ Teleconsultation with trauma surgeon and/or neurosurgeon as available. ▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for any patient with initial mild TBI who deteriorates to moderate/severe TBI.
	▪ Re-assess and Re-apply MARCH interventions. ▪ Ensure all basic nursing interventions noted above are completed by non-medical TCCC ASM and CLS personnel, CLS-trained service members and medics/corpsmen. ▪ Conduct inventory of all treatment supplies. ▪ Document all pertinent information on PCC Flowsheet (attached).
Role 1a	▪ Identification and local wound management of any open head wounds/skull fractures. Priorities should include hemorrhage control, removal of gross contamination, and protection/coverage of any exposed dura or brain matter. ▪ MACE2 examination per TCCC guideline. ▪ Serial GCS exams (Appendix E.) ▪ Identify signs of elevated or rising ICP per Appendix E.

PCC Role-based Guidance for Head Injury/TBI Management	
	▪ Initiate immediate treatment for signs of elevated ICP including initial bolus of 3% hypertonic saline (HTS) 250-500 ml. Alterative: 23.4% sodium chloride. ▪ Administer TXA as single 2gram IV or IO bolus (no second dose required). ▪ Communicate evacuation requirements (need for TBI evaluation, neurosurgery). ▪ Communicate re-supply requirements.

Role 1b	▪ Re-assess and re-apply MARCH interventions.
	▪ Administer antibiotics for any open head wounds or skull fracture. (See Antibiotics). Continue resuscitation until:
	  ▪ **Minimum**: palpable radial pulse or improved mental status
	  ▪ **Better**: SBP > 90 mmHg
	  ▪ **Best**: SBP between 100-110 mmHg
	  ▪ If SBP remains less than 100-110 mmHg despite appropriate resuscitation and hemorrhage control, a vasopressor agent should be started if available.
	  ▪ norepinephrine continuous infusion 0.1–0.4 mcg/kg/min
	  ▪ vasopressin continuous infusion 0.01-0.04 units
	** All use of pressers should be administered by role-based approved protocols or teleconsultation approval*
	▪ Serial neurologic checks and identify signs of elevated or rising intracranial pressure (Appendix E); If noted, the following interventions are recommended, if possible:
	  ▪ HTS administration (intermittent bolus versus continuous infusion) per Appendix E. Alternative: 23.4% sodium chloride.
	  ▪ Administer seizure prophylaxis (1G Levetiracetam), if available.
	  ▪ Supplemental oxygen to maintain O2 sats > 94%, ETCO2 if intubated with goal of norocapnia with pCO2 of 35-40.
	  ▪ Brief (less than 30 min) moderate hyperventilation to goal pCO2/ETCO2 20-30 may be performed for signs of impending/active herniation (pupil becomes fixed and dilated).
	  ▪ ** **Note**: Use hyperventilation only as a temporizing measure while additional ICP treatments are being administered or tactical evacuation is in process.
	▪ Repeat primary and secondary survey for any abrupt decline in the GCS or change in pupil exam to rule out non-neurologic causes.
	▪ Minimize analgesia and sedation agents, if possible, to preserve ability to obtain neurologic exam, but medical and operational considerations should take priority if deeper sedation or paralysis required.
	▪ Teleconsultation with trauma surgeon and/or neurosurgeon as available.
	▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for patients with initial mild TBI who deteriorates to moderate/severe TBI category.
	▪ Repeat triage evaluation and identification of non-survivable condition (or associated injuries) based on injury types/severity and required vs available resources.

Role 1c	▪ Continue serial neurologic checks including GCS and pupil exam at least hourly. ▪ Immediate seizure treatment with benzodiazepines, consider ketamine for refractory seizures. ▪ Temperature management and aggressive fever control. ▪ Teleconsultation with trauma surgeon and/or neurosurgeon as available. ▪ Upgrade evacuation priority and destination (facility with neurosurgical capabilities) for patients with initial mild TBI who deteriorates to moderate/severe TBI category.

PAIN MANAGEMENT (ANALGESIA AND SEDATION) FOR PCC

Background

A provider of PCC must first and foremost be an expert in TCCC and then be able to identify all the potential issues associated with providing analgesia with or without sedation for a prolonged (4-48 hr.) period.

These PCC pain management guidelines are intended to be used after TCCC Guidelines at the Role 1 setting, when evacuation to higher level of care is not immediately possible. They attempt to decrease complexity by minimizing options for monitoring, medications, and the like, while prioritizing experience with a limited number of options versus recommending many different options for a more customized fashion. Furthermore, it does not address induction of anesthesia before airway management (i.e. rapid sequence intubation).

Remember, YOU CAN ALWAYS GIVE MORE, but it is very difficult to take away. Therefore, it is easier to prevent cardiorespiratory depression by being patient and methodical. TITRATE TO EFFECT.

Priorities of Care Related to Analgesia and Sedation

1. Keep the casualty alive. DO NOT give analgesia and/or sedation if there are other priorities of care (e.g., hemorrhage control).
2. Sustain adequate physiology to maintain perfusion. DO NOT give medications that lower blood pressure or suppress respiration if the patient is in shock or respiratory distress (or is at significant risk of developing either condition).
3. Manage pain appropriately (based on the pain categories below).
4. Maintain safety. Agitation and anxiety may cause patients to do unwanted things (e.g., remove devices, fight, fall). Sedation may be needed to maintain patient safety and/or operational control of the environment (i.e. in the back of an evacuation platform).
5. Stop awareness. During painful procedures, and during some mission requirements, amnesia may be desired. If appropriate, disarm or clear their weapons and prevent access to munitions/ mission essential communications.

General Principles

- Consider pain in three categories:
    1. Background: the pain that is present because of an injury or wound. This should be managed to keep a patient comfortable at rest but should not impair breathing, circulation, or mental status.
    2. Breakthrough: the acute pain induced with movement or manipulation. This should be managed as needed. If breakthrough pain occurs often or while at rest, pain medication should be increased in dose or frequency as clinically prudent but within the limits of safety for each medication.
    3. Procedural: the acute pain associated with a procedure. This should be anticipated and a plan for dealing with it should be considered.

- Analgesia is the alleviation of pain and should be the primary focus of using these medications (treat pain before considering sedation). However, not every patient requires (or should receive) analgesic medication at first, and unstable patients may require other therapies or resuscitation before the administration of pain or sedation medications.
- Sedation is used to relieve agitation or anxiety and, in some cases, induce amnesia. The most common causes of agitation are untreated pain or other serious physiologic problems like hypoxia, hypotension, or hypoglycemia. Sedation is used most commonly to ensure patient safety (e.g., when agitation is not controlled by analgesia and there is need for the patient to remain calm to avoid movement that might cause unintentional tube, line, dressing, splint, or other device removal or to allow a procedure to be performed) or to obtain patient amnesia to an event (e.g., forming no memory of a painful procedure or during paralysis for ventilator management).
- In a Role 1 (or PCC) setting, intravenous (IV) or interosseous (IO) medication delivery is preferred over intramuscular (IM) therapies. The IV/IO route is more predictable in terms of dose-response relationship.
- Each patient responds differently to medications, particularly with respect to dose. Some individuals require substantially more opioid, benzodiazepine, or ketamine; some require significantly less. Once you have a "feel" for how much medication a patient requires, you can be more comfortable giving it to patient with a broad range of injuries.
- Similar amounts during redosing. In general, a single medication will achieve its desired effect if enough is given; however, the higher the dose, the more likely the side effects.
- Additionally, ketamine, opioids, and benzodiazepines given together have a synergistic effect: the effect of medications given together is much greater than a single medication given alone (i.e., the effect is multiplied, not added, so go with less than what you might normally use if each were given alone).
- Pain medications should be given when feasible after injury or as soon as possible after the management of MARCH and appropriately documented (medication administered, dose, route and time). Factors for delayed pain management (other than Combat Pill Pack) are need for individual to maintain a weapon/security and inability to disarm the patient.
- PCC requires a different treatment approach than TCCC. Go slowly, use lower doses of medication, titrate to effect, and re-dose more frequently. This will provide more consistent pain control and sedation. High doses may result in dramatic swings between over sedation with respiratory suppression and hypotension alternating with agitation and emergence phenomenon.

Drips and Infusions

For IV/IO drip medications: Use normal saline to mix medication drips when possible, but other crystalloids (e.g., lactated Ringer's, Plasmalyte, and so forth) may be used if normal saline is not available. DO NOT mix more than one medication in the same bag of crystalloid. Mixing medications together, even for a relatively short time, may cause changes to the chemical structure of one or both medications and could lead to toxic compounds.

If a continuous drip is selected, use only a ketamine drip in most situations, augmented by push doses of opioid and/or midazolam if needed. Multiple drips are difficult to manage and should only be undertaken with assistance from a Teleconsultation with critical care experience. Multiple drips are

most likely to be helpful in patients who remain difficult to sedate with ketamine drip alone and can "smooth out" the sedation (e.g., fewer peaks and troughs of sedation with corresponding deep sedation mixed with periods of acute agitation).

Other medications that should be available when providing narcotic pain control is Naloxone. If the patient receives too much medication, consider dilution of 0.4mg of naloxone in 9ml saline (40mcg/mL) and administer 40mcg IV/IO PRN to increase respiratory rate, but still maintaining pain control.

The PCC Pain Management Guideline Tables

These tables are intended to be a quick reference guide but are not standalone: you must know the information in the rest of the guideline. The tables are arranged according to anticipated clinical conditions, corresponding goals of care, and the capabilities needed to provide effective analgesia and sedation according to the minimum standard, a better option when mission and equipment support (all medics should be trained to this standard), and the best option that may only be available in the event a medic has had additional training, experience, and/or available equipment.

Medications in the table are presented as either give or consider:

- **Give**: Strongly recommended.
- **Consider**: Requires a complete assessment of patient condition, environment, risks, benefits, equipment, and provider training.

Use these steps when referencing the tables:

Step 1. Identify the clinical condition

- Standard analgesia is for most patients. The therapies used here are the foundation for pain management during PCC. Expertise in dosing fentanyl (OTFC or IV) and ketamine IV or IO is a must. Intramuscular and intranasal dosing of medications isn't recommended in a PCC setting.
- Difficult analgesia or sedation needed is for patients in whom standard analgesia does not achieve adequate pain control without suppressing respiratory drive or causing hypotension, OR when mission requirements necessitate sedating a patient to gain control over their actions to achieve patient safety, quietness, or necessary positioning.
- Protected airway with mechanical ventilation is for patients who have a protected airway and are receiving mechanical ventilatory support or are receiving full respiratory support via assisted ventilation (i.e. bag valve).
- Shock present is for patients who have hypotension, active hemorrhage, and/or tachycardia.

Step 2. Read down the column to the row representing your available resources and training.

Step 3. Provide analgesia/sedation medication accordingly.

Step 4. Consider using the Richmond Agitation-Sedation Scale (RASS) score (Appendix E) as a method to trend the patient's sedation level.

Table 10. PCC Role-based Guideline for Pain Management (Analgesia and Sedation)

PCC Role-based Guideline for Pain Management (Analgesia and Sedation)

TCCC-ASM | TCCC-CLS | TCCC-CMC | TCCC-CPP

Complete Basic TCCC Communication Plan for Pain Management then:

- Administer meloxicam and acetaminophen (pain medications in Joint First Aid Kit [JFAK]) per TCCC guidelines if not already given.
- Identify painful conditions that can be treated without the use of medications.
  - Fractures - apply splint per TCCC guidelines.
  - Exposed burns - burn care per TCCC guidelines.
  - Tourniquets will cause significant pain - DO NOT remove a tourniquet in an attempt to alleviate pain unless directed to do so by a higher medical authority.

Drug/Interactions/Dose	Onset	Duration	Side Effects
Acetaminophen ▪ Mild-moderate pain, able to fight ▪ Use with meloxicam ▪ 1 gram every 6 hours	<1 hr when given by mouth	4-6 hours	▪ Allergic Reaction (rare) ▪ Liver damage: limit daily dose of acetaminophen and acetaminophen-containing products (e.g., Percocet) to 4,000mg/day
Meloxicam ▪ Mild-moderate pain, able to fight ▪ Use with acetaminophen ▪ 15 mg daily	<1 hr when given by mouth	24 hours	▪ Reflux ▪ Abdominal pain ▪ Nausea/vomiting ▪ Diarrhea and/or constipation

Administer meloxicam and acetaminophen (in JFAK) per TCCC guidelines if not already given.

- Pain medications should be given when feasible after injury or as soon as possible after the management of MARCH and appropriately documented (medication administered, dose, route and time).
- Pain meds initiated in TCCC can often be continued in the PCC environment for both ongoing analgesia and sedation, as long as the duration and cumulative side effects are well understood and mitigated.

Drug/Interactions/Dose	Onset	Duration	Side Effects
OTFC (Oral Transmucosal Fentanyl Citrate) ▪ Moderate to severe pain, unable to fight without hemorrhagic shock or respiratory distress ▪ 800 mcg every 30 min	5 mins when given by mouth	20-40 minutes	▪ Respiratory/cardiac/mental status depression ▪ Nausea/vomiting ▪ Pruritus (itching) ▪ Constipation
Ketamine ▪ Moderate to severe pain, unable to fight with hemorrhagic shock or respiratory distress ▪ 30 mg (or 0.3 mg/kg) slow IV or IO push every 20 min ▪ May repeat ▪ Ketamine 50-100 mg (or 0.5-1 mg/kg) IM or IN every 20-30 min	30 secs IV or 1-5 mins IM	10-15 mins IV or 20-30 mins IM	▪ Cataleptic-like state (dissociated from the surrounding environment) ▪ Respiratory depression at higher doses (>1mg/kg), especially with fast administration IV/IO ▪ Hypersalivation (can be problematic in an austere setting) ▪ Increased blood pressure and heart rate. ▪ Nausea/vomiting

PCC Role-based Guideline for Pain Management (Analgesia and Sedation)			
▪ May repeat **For Sedation** ▪ 1-2 mg/kg slow IV push initial dose ▪ 300 mg IM (or 2-3 mg/kg IM) initial dose ▪ May repeat			
Ondansetron (Zofran) ▪ For nausea/vomiting ▪ 1-2 tabs PO/SL every 4-6 hours PRN ▪ 4 mg IV, may repeat 1 time in 2 hours if N/V returns	30 min - hr when given PO or SL, 5-10 mins when given IV	3-6 hours	▪ Drowsiness ▪ Fatigue ▪ Anxiety
Naloxone (Narcan) ▪ For complete or partial reversal of opioid depression (respiratory/cardiac/mental) ▪ 0.4-2 mg IV/IM/IO ▪ May repeat every 2-3 minutes (MAX dose 10 mg)	1-2 minutes IV or 2–5 minutes IM/IO	30-90 mins Note: some opioids have longer duration so naloxone may need to be repeated	▪ Abrupt withdrawal reaction from opioid depression should be anticipated and preparations should be made. ▪ This reaction may include vomiting, sweating, tachycardia, increased blood pressure, agitation.
▪ Pain medications should be given when feasible after injury or as soon as possible after the management of MARCH and appropriately documented (medication administered, dose, route and time). ▪ Pain meds that are initiated in TCCC can often be continued in the PCC environment for both ongoing analgesia and sedation, as long as the duration and cumulative side effects are well understood and mitigated.			
Drug/Interactions/Dose	Onset	Duration	Side Effects
Fentanyl ▪ Moderate to severe pain, unable to fight without hemorrhagic shock or respiratory distress ▪ 50 mcg IV (0.5-1 mcg/kg) or 100 mcg IN, may repeat every 1-2 hours	1-2 minutes when given IV	30-60 minutes	▪ Respiratory/cardiac/ mental status depression ▪ Nausea/vomiting ▪ Pruritus (itching) ▪ Constipation
Ketamine ▪ Moderate to severe pain, unable to fight with hemorrhagic shock or respiratory distress ▪ 30 mg (or 0.3 mg/kg) slow IV or IO push every 20min ▪ May repeat ▪ Ketamine 50-100 mg (or 0.5-1 mg/kg) IM or IN every 20-30 min	30 secs IV or 1–5 mins IM	10–15 mins IV or 20–30 mins IM	▪ Cataleptic-like state (dissociated from the surrounding environment) ▪ Respiratory depression at higher doses (>1mg/kg), especially with fast administration IV/IO ▪ Hypersalivation (can be problematic in an austere setting) ▪ Increased blood pressure and heart rate. ▪ Nausea/vomiting

PCC Role-based Guideline for Pain Management (Analgesia and Sedation)			
▪ May repeat **For sedation** ▪ 1-2 mg/kg slow IV push initial dose ▪ 300 mg IM (or 2-3 mg/kg IM) initial dose **For longer duration analgesia** ▪ Slow IV infusion 0.3 mg/kg in 100 ml 0.9% sodium chloride over 5-15 minutes every 45 minutes prn for IV or IO			
▪ When available and applicable, other medications can be considered. ▪ These medications should be used based on local protocols and policies put in place by your medical director or through direct teleconsultation guidance.			
Drug/Interactions/Dose	Onset	Duration	Side Effects
Midazolam (Versed) ▪ For sedation and anxiolysis; will also cause anterograde amnesia ▪ 2-4 mg IM ▪ 0.5-1mg IV (push slowly over 1-2 minutes)	15-20 mins when given IM, 2 mins when given IV	1-6 hrs when given IM, 15 min-6 hrs (HIGH variability)	▪ Drowsiness ▪ Respiratory depression ESPECIALLY when used with any narcotic ▪ Nausea/vomiting
Acetaminophen/Hydrocodone (Norco) ▪ For moderate-severe pain ▪ Comes in multiple strengths of hydrocodone - 5/7.5.10 mg ▪ 1-2 tabs PO every 4-6 hours PRN for 5mg hydrocodone strength	10-20 minutes	3-4 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation ▪ Nausea/vomiting ▪ Itching Note: contains acetaminophen. Be aware of total dose when given with other drugs that contain acetaminophen
Acetaminophen/Oxycodone (Percocet) ▪ For moderate-severe pain ▪ Comes in multiple strengths of oxycodone - 5/7.5/10 mg ▪ 1-2 tabs PO every 4-6 hours PRN for 5mg oxycodone dose	10-20 minutes	3-4 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation ▪ Nausea/vomiting ▪ Itching Note: contains acetaminophen. Be aware of total dose when given with other drugs that contain acetaminophen
Hydromorphone (Dilaudid) ▪ For severe pain ▪ 1-2 mg IM ▪ 0.5 - 1 mg IV	15-20 mins when given IM, 2 mins when given IV	3-4 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation ▪ Nausea/vomiting ▪ Itching
Morphine ▪ For severe pain ▪ 5-10 mg IM	15-20 mins when given IM, 2-5	3-4 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation

PCC Role-based Guideline for Pain Management (Analgesia and Sedation)				
	▪ 2 - 4 mg IV	mins when given IV		▪ Nausea/vomiting ▪ Itching
	Tramadol (**Ultram**) ▪ For moderate-severe pain ▪ 1-2 tabs PO every 4-6 hours PRN (DO NOT exceed 400 mg tramadol/day)	10-20 minutes	4-6 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation ▪ Nausea/vomiting ▪ CNS stimulation including seizures at high doses ▪ Note: Some preparations (i.e., Ultram) contain acetaminophen. Be aware of total dose when given with other drugs that contain acetaminophen.
	Codeine/acetaminophen ▪ For moderate-severe pain ▪ 1-2 tabs PO every 4-6 hours PRN (for tabs with 15mg Codeine)	30 minutes - 1 hour	4-6 hours	▪ Drowsiness ▪ Respiratory depression ▪ Sedation ▪ Nausea/vomiting ▪ Itching ▪ Note: Contains acetaminophen. Be aware of total dose when given with other drugs that contain acetaminophen.
	▪ In some cases, local anesthetics or even limited regional anesthesia is the best option for pain control (For more information, see Military Analgesia Regional Anesthesia Guidelines.) ▪ While side effects are real and toxic levels of these drugs must be understood and avoided, the benefit can often be achieved without sedation when appropriate for the tactical environment.			

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

Special Considerations

Patient Monitoring During Sedation

Patients receiving analgesia and sedation require close monitoring for life-threatening side-effects of medications.

- **Minimum**: Blood pressure cuff, stethoscope, pulse oximeter; document vital signs trends.
- **Better**: Capnography in addition to minimum requirements
- **Best**: Portable monitor providing continuous vital signs display and capnography; document vital signs trends frequently.

Analgesia and Sedation for Expectant Care (i.e. End-of-Life Care)

An unfortunate reality of our profession, both military and medical, is that we encounter clinical scenarios that will inevitably end in a patient's death. In these situations, it is a healthcare provider's obligation to give palliative therapy to minimize the person's suffering. In these circumstances, the use of opioid analgesics and sedative medications is therapeutic and indicated, even if these medications worsen a patient's vital signs (i.e., cause respiratory depression and/or hypotension). If a patient is expectant:

- Teleconsultation
- Prepare to:
  - Give opioid until the patient's pain is relieved. If the patient is unable to communicate their pain, give opioid medication until the respiratory rate is less than 20/min.
  - If the patient complains of feeling anxious (i.e., is worrying about the future but not complaining of pain) or he cannot express himself but is agitated despite having a respiratory rate less than 20/min, give a benzodiazepine until the anxiety is relieved or the patient is sedated (i.e., is not feeling anxious or is no longer agitated).
- Position the patient as comfortably as possible. Pad pressure points.
- Provide anything that gives the patient comfort (e.g., water, food, cigarette).
- Under no circumstances should paralytics be used without analgesia/sedation

*Link to Pain, Anxiety and Delirium, 26 April 2021 CPG [16]

ANTIBIOTICS, SEPSIS, AND OTHER DRUGS - PCC

Background

Complete Basic TCCC Management Plan for Antibiotics then:

Antibiotics should be given immediately after injury or as soon as possible after the management of MARCH and Pain Management and appropriately documented (medication administered, dose, route and time).

Confirm that initial TCCC dose of moxifloxacin (Avelox®) or Ertapenem (Invanz®) have already been given for any penetrating trauma. If available, administer tetanus toxoid IM as soon as possible.

Antibiotics should be given daily for seven to 10 days, depending on the type of antibiotic given (see below tables for antibiotics). When able/available, transition IV/IO antibiotics to PO as soon as possible to conserve supplies and equipment.

Table 11. TCCC Antibiotics

TCCC Antibiotics	
Moxifloxacin (Avelox®)	Administer 400mg PO daily for 10 days
Ertapenem (Invanz®)	Administer 1g daily IV/IO/IM for 10 days
IV/IO to PO transition	When transitioning from Ertapenem to Moxifloxacin, begin Moxifloxacin immediately after the final dose of Ertapenem for antibiotic overlap

Table 12. Alternative Antibiotics

(used if supplies of TCCC antibiotics are limited, or as directed by medical control)

Alternate Antibiotics			
	Good	**Better**	**Best**
Soft Tissue Injury	Cefalexin PO or Bactrim DS PO Topical: Bacitracin	Cefazolin IM/IV/IO	Moxifloxacin PO or Ertapenem IV/IO Topical: Mupriocin
Suspected MRSA	Topical: Mupirocin	Ertapenem IV/IO	Moxifloxacin PO or Ertapenem IV/IO + Vancomycin
Open Fx (I/II)	Beta-lactam Allergy: Clindamycin IV/IO	Cefazolin IV/IO	Ertapenem IV/IO or Moxifloxacin PO
Open Fx (III) no contamination	Beta-lactam Allergy: Clindamycin IV/IO + Levofloxacin IV/IO	Ceftriaxone IV/IO	Ertapenem IV/IO or Moxifloxacin PO
Open Fx (III) soil or fecal contamination	Beta-lactam Allergy: Levofloxacin IV/IO + Metronidazole IV/IO	Ceftriaxone IV/IO + Metronidazole IV/IO	Ertapenem IV/IO or Moxifloxacin PO
Penetrating Head Injury		Ceftriaxone IV/IO + Metronidazole IV/IO	Ertapenem IV/IO or Moxifloxacin PO
Penetrating Chest Injury			Ertapenem IV/IO or Moxifloxacin PO
Penetrating Abdominal Injury		Ceftriaxone IV/IO + Metronidazole IV/IO	Ertapenem IV/IO or Moxifloxacin PO

Alternate Antibiotics			
Burns (*only* when sepsis is suspected)			Ertapenem IV/IO or Moxifloxacin PO
Eye Injuries	Erythromycin ointment/drops	Ciprofloxacin drops (or if penicillin allergy)	Moxifloxacin PO or Ertapenem IV/IO
Dental Injuries	Pen-VK or Augmentin PO	Clindamycin PO (or IV/IO) or if penicillin allergy	Moxifloxacin PO or Ertapenem IV/IO

Sepsis Management

- Blunt or penetrating injuries may cause sepsis in untreated or undertreated patients
- Early recognition of impending sepsis and immediate treatment are imperative to improve changes of survival
- Maintain a high degree of suspicion for signs of early and/or progressing sepsis while performing continuous triage
- Sepsis is defined as suspected or proven infection plus evidence of end organ dysfunction.
- The National Early Warning Score (NEWS)[17] is an aggregate scoring system indicating early physiologic derangements:

Table 13. Physiologic Parameters and NEWS Score

Physiologic Parameters	**3**	**2**	**1**	**0**	**1**	**2**	**3**
Respiratory Rate	≤8		9-11	12-20		21-34	≥25
Oxygen Saturation	≤91	92-93	94-95	≥96			
Temperature	≤35.0		35.1-36.0	36.1-38.0	38.1-39.0	≥39.1	
Systolic BP	≤90	91-100	101-110	111-219			
Heart Rate	≤40		41-50	51-90	91-110	111-130	≥131
Level of Consciousness				A			V,P,U

- For the purposes of this guideline, a NEWS score of >2 is used to increase the sensitivity for detection of and evaluation for sepsis.
- Early teleconsultations should be used for any signs of sepsis
- Additional parenteral antibiotics may be required to treat sepsis as well as vasopressors.
- All use of pressers should be administered by role-based approved protocols or teleconsultation approval.

NOTE: Surgical telemedicine consultation is highly recommended to guide management of intra-abdominal infections (i.e. appendicitis, cholecystitis, diverticulitis, abdominal abscess).

Sepsis Treatment

Table 14. Sepsis Treatments/Interventions

Intervention	Paradigm
Antimicrobial Therapy	▪ **Minimum** - Moxifloxacin 400 mg PO daily ▪ **Better** - Ertapenem 1 gram IV/IO every 24 hours OR ceftriaxone 2 grams IV/IO every 24 hrs ▪ **Best -** ceftriaxone 2 grams IV/IO every 24 hrs., PLUS vancomycin 1.5 mg/kg IV/IO every 12 hours, PLUS metronidazole 500 mg IV/PO/IO every 8 hours
Antiparasitic Regimens	▪ **Minimum** - Atovaquone/progauanil (Malarone) 4x3 regimen - 4 tablets PO daily for 3 days ▪ **Better/Best** - Artemether/lumefantrine (Coartem) 4 tablets PO initially, then 4 tablets after 8 hours, then 4 tablets PO twice daily for 2 more days (24 tablets total)
Antifungal Regimens	▪ **Minimum/Better/Best** - Fluconazole 400 mg PO/IV daily

Fluid Resuscitation	▪ **Minimum** - In the absence of IV/IO capability, have the patient drink water
	▪ If available, include electrolyte oral rehydration solution, especially for patients who cannot consume food
	▪ **Better** - IV/IO crystalloids:
	  ▪ Initial rapid infusion of 30 ml/kg should be given upon identification of sepsis
	  ▪ LR or NS to maintain SBP > 90mmHg or MAP ≥ 65 mmHg
	  ▪ If plasma is being given that volume can count toward the 30 ml/kg goal
	▪ **Best** - The same fluid resuscitation strategy as above with the addition of a urinary catheter for more precise measuring of UOP

Vasopressors	▪ After fluid resuscitation, if there is no observed positive change in SBP, MAP, UOP and/or mental status, vasopressor medications should be given ▪ *All use of pressers should be administered by role-based approved protocols or teleconsultation approval* ▪ **First-line** - norepinephrine infusion ▪ **Second-line** - epinephrine infusion ▪ Refer to Drip table below for preparation, starting dose, and drip rates
Additional Medications	▪ Consider hydrocortisone or dexamethasone administration for possible adrenal insufficiency if there is a poor response to vasopressor initiation/titration ▪ Administer antipyretics (acetaminophen, if available. Non-steroidal anti-inflammatory drugs [NSAIDs] should be avoided as they may impair renal function)

Table 15. Epinephrine 1:10,000 (Adrenaline) or Norepinephrine (Levophed) Drip

0.9% NaCl IVF Bag Size	Add to bag: EPI (or NOREPI): 1:10,000 (0.1 mg or 100mcg)/mL	Starting Dose (mcg/min)	DRIP SET:10gtts (Drops/mL) DRIP RATE: (Drops/min or gtts/min)	DRIP SET: 15gtts (Drops/mL) DRIP RATE: (Drops/min or gtts/min)
50 mL	1mL (100mcg)	4 mcg/min	20 drops/min	30 drops/min
100 mL	2mL (200mcg)	4 mcg/min	20 drops/min	30 drops/min
250 mL	5mL (500mcg)	4 mcg/min	20 drops/min	30 drops/min
500 mL	10mL (1mg)	4 mcg/min	20 drops/min	30 drops/min
1000 mL (1L)	20mL (2mg)**	4 mcg/min	20 drops/min	30 drops/min

**This is the least recommended approach as it commits a high volume of epinephrine to a large bag. If the patient's vital signs (BP/MAP/HR) stabilize, the bag must be discontinued and the medic risks wasting some of their resources – "you can mix a drug in an IV bag, but you can't take it out."

Ancillary Medications

During PCC, additional medications may be required during the extended treatment of casualties, in addition to pain and antibiotic medications. These medications may have synergistic effects to further reduce pain or fever. Some medications may be utilized to treat side-effects of medications, to include nausea or other GI related issues.

Deep vein thrombosis (DVT) prophylaxis is also recommended for patients that are expected to be in a PCC setting for greater than 48 hours that have achieved hemostasis from wounds or are not at risk for further hemorrhage.

Table 16. Ancillary Medications

	Minimum	Better	Best
Airway	Albuterol MDI Suctioning: Sterile water or 0.9% saline	Albuterol (Neb)	Albuterol (Neb) + Atrovent (Neb)
*Antipyretic	Meloxicam	Acetaminophen PO/PR or Ibuprofen	Acetaminophen IV/IO or Ketoralac IM/IV/IO
Anxiety / Behavioral	See "Pain and Sedation"		
DVT Prophylaxis	Aspirin PO	Heparin SQ	Lovenox SQ
Hydration (PO)	Water	Water + salt + sugar	Water + Gatorade (or other oral rehydration salt)
Hydration (IV/IO)	0.9% Saline or Lactated Ringers	Plasma-Lyte	
Nausea / Vomiting	Alcohol Pad (inhale vapor)	Ondansetron PO or ODT	Ondansetron IV/IO or Metoclopramide IV/IO
GI Medications	Ranitidine PO	Prilosec PO	Protonix IV/IO H1/H2 Blockers IV/IO
GI - Constipation	Bisacodyl PO Glycerin Suppository	Mirilax PO Senna PO	Enema
Sleep	Melatonin PO	Diphenhydramine PO	Zolpidem PO Temazepam PO
Other Medications:	▪ Oral Care (toothbrush/tooth paste and chapstick) ▪ Eye drops (intubated/sedated) ▪ Multi-Vitamins (PO daily) ▪ Animal Bites: Rabies Vaccine and Rabies Immunoglobulin ▪ HIV Prophylaxis (exposure from combat: civilians or enemy forces): PEP Guidance ▪ Regional Medications: Ensure continuing prophylaxis (malaria, etc)		

*Antipyretic: Use caution with NSAIDs with urgent or priority patients. Ensure patient can void normally (no impaired renal function).

*Link to Sepsis Management in Prolonged Field Care, 28 Oct 2020 CPG [19]

WOUND CARE AND NURSING - PCC

Background

Nursing interventions may not appear important to the medical professionals caring for a patient, but such interventions greatly reduce the possibility of complications such as DVT, pneumonia, pressure sores, wound infection, and urinary tract infection; therefore, essential nursing and wound care should be prioritized in the training environment. Critically ill and injured casualties are at high risk for complications that can lead to adverse outcomes such as increased disability and death. Nursing care is a core principle of PCC to reduce the risk of preventable complications and can be provided without costly or burdensome equipment.[20]

- Using a nursing care checklist assists with developing a schedule for performing appropriate assessments and interventions.
- Cross training all team members on these interventions prior to deployment will lessen the demand on the medic, especially when caring for more than one patient.
- Prolonged Casualty Care Flowsheets, Nursing Care Checklists, Nursing Care Plans, Assessment/Intervention Packing List, and Recommended Nursing Skill Checklist for Clinical Rotations are included as a PCC Guidelines Appendix. (Also located in JTS Nursing Intervention in Prolonged Field Care CPG, 22 Jul 2018 [18]).

Pre-deployment, Mission Planning, and Training Considerations

- Hands-on experience is optimal; simulation is a reasonable substitute
- Practice with minimal technology so you are prepared when you lose access to electricity, water
- Regular monitoring, reassessment, and intervention is lifesaving but can be resource-intensive
- Utilize the Recommended Nursing Skill Checklist for Clinical Rotations included in Appendix B to maximize training opportunities.

Table 17. PCC Role-based Guidelines for Nursing Care and Wound Management

PCC Role-based Guidelines for Nursing Care and Wound Management						
TCCC-ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP	**** All Personnel - Complete Basic TCCC Management Plan for Nursing/Wound Management then:*** ▪ Many "nursing" interventions are actually basic soldier skills that need to be performed on those casualties who cannot perform them on themselves. ▪ Therefore, many traditional non-medical tasks are listed at the Tier 1 level since they can essentially be performed by anyone, but the activity can be overseen by medical personnel.		
				Interventions	Frequency	Paradigm
				Lip care	Every hour	▪ **Minimum**: Commercial lip balm ▪ **Better**: Moisturizing lotion ▪ **Best**: Petroleum jelly
				Oral/Nasal Care	24 hours	▪ **Minimum**: Rotate site around mouth/nares, as feasible. ▪ **Better**: Rotate site and suction. ▪ **Best**: Rotate and suction with commercial device.
				Oral/Dental Care	Every 12 hours	▪ **Minimum**: Brush with gauze, water and gloved finger ▪ **Better**: Brush with tooth brush with toothpaste. ▪ **Best**: Use tooth brush with Chlorhexidine rinse.
				Cough/Deep Breathing	Every hour	▪ **Minimum**: Encourage deep breathing/forced cough x 10. ▪ **Better**: Sit up. Encourage deep breathing/forced cough x 10. ▪ **Best**: Sit up, turn, and encourage deep breathing with incentive spirometer/forced cough x 10.
				Repositioning/ Check Padding	Every 2 hours	▪ **Minimum**: Turn to opposite side, pad with clothing or textiles. ▪ **Better**: Turn to opposite side, pad with pillows or blankets. ▪ **Best**: Turn to opposite side, pad with pillows to all bony prominences and between legs.
				Splint Care	Every 2 hours	▪ **Minimum**: Use improvised splints (i.e. wood fence, plank). ▪ **Better**: Use commercial splinting device (e.g., SAM splint). ▪ **Best**: Use ortho-fiberglass splint with fluffing and elastic wrap. ▪ ** Re-check all pulses after splint placemen.t
				Hypothermia Prevention	Continuous	▪ **Minimum**: Wrap patient in dry clothes or blankets. ▪ **Better**: Wrap patient in commercially available hypothermia prevention kit, using air-activated heating element. ▪ **Best**: As above, add use of warmed, forced air and infusion of warmed fluids using commercially available devices.
				Head Injury	Continuous	Elevate head of bed 30 degrees and then: ▪ **Minimum**: Lay patient against ruck sack/backpack ▪ **Better**: Pillows or blankets ▪ **Best**: NATO litter back rest
				Non-medical Interventions	Every hour	▪ **Minimum**: Distract the patient and perform guided imagery. ▪ **Better**: Splint wounds, pad boney prominences, provide ice packs to injured/swollen areas (or, alternate with warm packs). ▪ **Best**: As above, combine both elements.
				Psycho-social Needs	Continuous	▪ **Minimum**: Speak in calm tone, addressing casualty concerns, to reduce fear and anxiety. ▪ **Better**: Support with caring touch, listening to fears/concerns; explain all procedures. ▪ **Best**: Institute rest/sleep cycle system to minimize delirium.

Nutrition	Every 4-6 hours	▪ **Minimum**: If patient is alert, encourage oral food/water intake. ▪ **Better**: As above, use MRE protein powder mixed with water. ▪ **Best**: As above, use commercially available tube feeding products or protein shakes.
Hygiene	Every 24 hours	▪ **Minimum**: Rinse face, armpits, and groin with warm water, soap, and gauze roll. ▪ **Better**: As above, use baby wipes or wash cloth. ▪ **Best**: As above, use chlorhexidine-impregnated cleansing wipes.
Bowel Management	As required	▪ **Minimum**: Cleanse soiled skin as described for bath; reapply new dressings/hypothermia management as appropriate. ▪ **Better**: As above, add a cloth/linen/plastic barrier to protect wounds/hypothermia management kit from future soiling. ▪ **Best**: As above, add barrier cream to skin for protection against breakdown.

▪ Perform all recommended interventions from guidelines for above Tier level.
▪ Additional interventions include:

Intervention	Frequency	Paradigm
IV/IO Site Care		▪ **Minimum**: Flush intravenous catheter every 12 hours; change intravenous infusion tubing every 96 hours. ▪ **Better**: Flush intravenous catheter every 8 hours; change intravenous infusion tubing every 72 hours. ▪ **Best**: Flush intravenous catheter every 4 hours. Change intravenous infusion tubing every 48 hours. ▪ For IO: monitor the site closely for skin compromise (underneath the hub of the IO); if possible, convert to an IV within 24 hours.
Wound Irrigation	Every 24 hours	▪ **Minimum**: Irrigate wound with potable water (cooled before use if boiled) poured across wound ▪ **Better**: As above, use 10cc syringe and 18-gauge angio-catheter. ▪ **Best**: As above, using sterile saline or sterile water or appropriate antimicrobial cleaning solution (i.e. Dankins).
Dressing Change		▪ **Minimum**: Reinforce dressings. ▪ **Better**: Replace when soiled. ▪ **Best**: Change every 24 hours.

▪ Ensure above nursing interventions are completed by non-medical TCCC ASM and CLS personnel.
▪ Conduct inventory of all resources.
▪ Document all pertinent information on PCC Flowsheet (attached).
▪ Additional interventions include:

Intervention	Frequency	Paradigm
Suction mouth/airway, if indicated	As often as required	▪ **Minimum**: Toomey syringe attached to thin tubing ▪ **Better**: Manual suction device ▪ **Best**: Powered suction device
Monitor assisted ventilation	Continuous: every hour	▪ **Minimum**: Use bag-valve-mask ventilation. ▪ **Better**: Mechanical ventilator (without oxygen support), titrate settings based on pulse oximetry. ▪ **Best**: Mechanical ventilator (with oxygen support).
IV Fluid Calculation		▪ **Minimum**: Estimate fluid rate using infusion drip rate calculation. ▪ **Better**: Use “dial-a-flow” technology to control rate of infusion. ▪ **Best**: Use commercial infusion pump.

Deep Vein Thrombosis Prevention ***Pay attention to any wounds to the affected limb***	Every 1-2 hours	▪ **Minimum**: Massage lower extremities ▪ **Better**: As above; add application of compression stockings or elastic bandages to improve venous return. ▪ **Best**: As above; add application of commercial mechanical compression stockings.
Head Injury (Serial Neuro Exams)		▪ **Minimum**: Assess pupillary response, GCS and level of consciousness/orientation, every 8-12 hours; MACE Exam x 1. ▪ **Better**: Neuro exam (as above) every 4 hrs; MACE exam every 24 hrs. ▪ **Best**: Neuro exam (as above) every 1 hr, MACE exam every 24 hrs.
Hyperthermia Prevention/ Treatment		▪ **Minimum**: Expose skin to air. ▪ **Better**: Place cold, wet cloths to groin, neck, armpits (ice packs may cause hypothermia). ▪ **Best**: Use of cooled, forced air and infusion of cooled fluids using commercially available devices.
Administer Antibiotics		▪ **Minimum**: Provide oral or intramuscular injection of antibiotics per CPG. ▪ **Better**: Administer intravenous infusion of broad-spectrum antibiotics, per CPG. ▪ **Best**: Administer wound- or mechanism-specific antibiotics via intravenous infusion, as directed by provider oversight.
Pain Control		▪ **Minimum**: Intermittent dosing of analgesics, given: oral/intramuscular/intravenous/subcutaneous ▪ **Better**: Continuous infusion of analgesics ▪ **Best**: Regional nerve blocks

- Ensure nursing interventions noted above are completed by non-medical TCCC ASM and CLS personnel
- Conduct inventory of all resources
- Document all pertinent information on PCC Flowsheet (attached)
- Additional interventions include:

Intervention	Frequency	Paradigm
Suction Advanced Airway	Every hour	▪ **Minimum**: Manual suction device or improvised suction device, such as a 25cm length portion of IV tubing connected to a 60mL syringe ▪ **Better**: Open suction tube, suction machine ▪ **Best**: Closed inline suction tube, suction machine
Oro/naso-gastric Tube Management		▪ **Minimum**: Cleanse area and rotate position every 12 hours; flush with water every 12 hours (check residuals prior) ▪ **Better**: As above, every 8 hours (check residuals prior) ▪ **Best**: As above, every 4 hours (check residuals prior)
Foley Care	24 hours	▪ **Minimum**: Cleanse around catheter insertion site as part of bath, every 24 hours. ▪ **Better**: Cleanse around catheter insertion site using soap and water, every 12 hours. ▪ **Best**: Cleanse around catheter insertion site using chlorhexidine-impregnated cleansing wipes, every 12 hours.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

*Link to Acute Traumatic Wound Care in the Prolonged Field Care Setting, 24 Jul 2017 CPG [21]

SPLINTING AND FRACTURE MANAGEMENT - PCC

Table 18. Splinting and Fracture Treatment

Intervention	Paradigm
Litter Padding	▪ **Minimum** - Excess uniforms or other textiles ▪ **Better** - Blankets or military sleep pad ▪ **Best -** Blankets or military sleep pad
Splint Placement	▪ **Minimum** - Improvised splints (wood fence, metal plank, etc.) ▪ **Better** - Commercial splinting device (e.g., SAM splint) ▪ **Best -** Commercial splinting device (e.g., SAM splint) ▪ *Re-check all pulses after splint placement*
Pressure Injury Prevention	▪ Examine skin, including nares and mouth, for changes and ensure splints are fitted properly and pulses are present below splint. ▪ Monitor for allergic reactions to tape, developing erythema, excessive dryness, pressure indenting the skin, cracking, or breakdown. ▪ **Minimum** - As described above, every 2 hours ▪ **Better** - As above, adding padding to elevate bony prominences off of ground/litter/bed ▪ **Best -** As above, adding commercial barrier creams and pressure injury dressings (e.g., Mepilex) to bony prominences

Straps	▪ Patient secured for transport with padding/hypothermia considerations
	▪ All patient care items secured for flight or seaboard transport
	  ▪ Waterproof outer shell (HPMK)
	  ▪ Packaged to resist heavy wind from rotor wash and wind

Litter Padding	▪ **Minimum** - Allow casualty to maintain airway ▪ **Better** - Facial burns may be associated with inhalation injury. Aggressively monitor airway status and place the casualty in a recovery position IAW TCCC Guidelines ▪ **Best -** Given a trauma casualty who is unresponsive or has an airway obstruction, perform a Head-Tilt Chin Lift or Jaw-thrust maneuver to open the airway IAW with TCCC guidelines

Link to JTS Orthopaedic Trauma: Extremity Fractures CPG, 26 Feb 2020[22]

BURN TREATMENT - PCC

Background

- Interrupt the burning process
- Address any life-threatening process based on MARCH assessment as directed by TCCC.
- A burned trauma casualty is a trauma casualty first
- All TCCC skills can be performed through burned tissue

Burn Characteristics

- **Superficial burns (1st degree)** appear red, do not blister, and blanch readily.
- **Partial thickness burns (2nd degree)** are moist and sensate, blister, and blanch.
- **Full thickness burns (3rd degree)** appear leathery, dry, non-blanching, are insensate, and often contain thrombosed vessels

Table 19. PCC Role-Based Guidelines for Burn Management

▪ PCC Role-based Guidelines for Burn Management					
TCCC-ASM	**TCCC-CLS**	**TCCC-CMC**	**TCCC-CPP**	▪ Perform primary and secondary surveys for any trauma patient. Acute injuries found in the primary and secondary survey should be addressed as per standard trauma protocols ▪ Avoid becoming distracted by the appearance of burned tissues.	
				Intervention	Paradigm
				Airway (Roles 1a/1b/1c)	▪ **Minimum** - Allow casualty to maintain airway. ▪ **Better** - Facial burns may be associated with inhalation injury. Aggressively monitor airway status and place the casualty in a recovery position IAW TCCC Guidelines. ▪ **Best** - Given a trauma casualty who is unresponsive or has an airway obstruction, perform a Head-Tilt Chin Lift or Jaw-thrust maneuver to open the airway in accordance with TCCC guidelines.
				Fluid Resuscitation (Roles 1a/1b/1c)	▪ Estimate body total surface area (TBSA) burned using the Rule of Nines initially (DD Form 1380). ▪ Note - Superficial (First-degree burns) are NOT used in the TBSA calculation. ▪ If burns >20% TBSA, fluid resuscitation should be initiated as soon as IV/IO access is established. ▪ **Minimum** - Oral intake of water ▪ **Better** - Oral intake of electrolyte solution ▪ **Best** - Oral intake of electrolyte solution
				Hypothermia (Roles 1a/1b/1c)	▪ Hypothermia prevention is extremely important for burn patients. ▪ For Burns >20%, place the casualty in the Heat-Reflective Shell or Blizzard Survival blanket for the Hypothermia Prevention Kit to both cover the burned areas and prevent hypothermia.

Pain Control	Analgesia in accordance with the PCC Guidelines may be administered to treat burn pain.
Wounds (Roles 1a/1b)	▪ **Minimum** - Cover with clean sheet or dry gauze. Leave blisters intact. Avoid wet dressings. ▪ **Better** - Clean wounds by washing with any clean water (preferably with antibacterial soap if available), dress wounds with any available dressings; optimize wound and patient hygiene to the extent possible given the environment. ▪ **Best** - Clean wounds by scrubbing gently with gauze and clean water, followed by gauze dressing.
Wounds (Role 1c)	▪ **Best** - Clean wounds by scrubbing gently with gauze and **chlorhexidine gluconate solution (if available)** in clean water, followed by gauze dressing. Repeat daily. ▪ Monitor vital signs.
▪ Ensure all interventions noted above are completed by TCCC ASM and CLS personnel. ▪ Conduct inventory of all resources. ▪ Document all pertinent information on PCC Flowsheet (attached). ▪ Additional interventions include:	
Intervention	Paradigm
Airway (Roles 1a/1b/1c)	▪ **Minimum** - Allow casualty to maintain airway. ▪ **Better** - Facial burns may be associated with inhalation injury. Aggressively monitor airway status and consider early surgical airway for respiratory distress or oxygen saturation and/or EtCO2 (purple-gold colorimetric device). ▪ **Best** - Given a trauma casualty who is unresponsive or has an airway obstruction, consider early surgical airway.
Fluid Resuscitation (Roles 1a/1b/1c)	▪ **Minimum** - Oral intake of water. Rectal infusion of up to 500mL/h can be supplemented with oral hydration. ▪ **Better** - Oral intake of electrolyte solution. ▪ **Best** - Start intravenous (IV) or intraosseous (IO) administration immediately. NOTE - an IV/IO can be placed through burned skin if necessary. ▪ Use isotonic crystalloids (i.e. Lactated Ringers). ▪ DO NOT circumferentially tape lines around extremities; this may further impede circulation and cause limb ischemia as extremities swell during resuscitation. ▪ NO bolus (unless hypotensive, in which case, bolus only until palpable pulses are restored). ▪ Initial IV rate 500mL/h; start while completing initial assessment ▪ Give fluids per TCCC burn treatment guidelines. ▪ If resuscitation is delayed, DO NOT try to “catch up” by giving extra fluids. ▪ Blood products may be used in major burn resuscitation due to coagulopathy, anemia, and bleeding from escharotomy sites or other traumatic injuries. ▪ Maintain a UOP of 30-50mL/hr. in adults; decrease or increase isotonic fluid rate by 20-25% per hour. ▪ If UOP > 50 mL/hr., then decrease the fluid rate by 20-25% for the next hour and reassess. ▪ Minimize fluid administration while maintaining organ perfusion; hour-to-hour fluid management is critical.

	▪ **8-12 hours post-burn**, if the hourly IV fluid rate exceeds 1500mL/hr. or if the projected 24- hour total fluid volume approaches 250 mL/kg consult burn team or medical director. ▪ **24–48 hours post burn**, plasma is lost into the burned and unburned tissues, causing hypovolemic shock (when burn size is >20%). The goal of burn-shock resuscitation is to replace these ongoing losses while avoiding over-resuscitation. ▪ **48-72 hours post-burn**, completion of the resuscitation is marked by stabilizing hemodynamic parameters and reduction of IV fluid rate to a maintenance level.
Hypothermia (Roles 1a/1b/1c)	▪ Hypothermia prevention is extremely important for burn patients. ▪ For Burns >20%, place the casualty in the Heat-Reflective Shell or Blizzard Survival blanket for the Hypothermia Prevention Kit to both cover the burned areas and prevent hypothermia. ▪ Use Blood/Fluid Warmer as needed and if available.
Pain Control (Roles 1a/1b/1c)	Analgesia in accordance with the PCC Guidelines may be administered to treat burn pain.
Medications (Roles 1a/1b)	▪ Prophylactic antibiotics (oral or IV) are not indicated for burn injury in the absence of infection. ▪ Penetrating wounds or open fractures should be treated with antibiotics according to current TCCC guidelines.
Medications (Role 1c)	▪ After several days, if the patient develops cellulitis (spreading erythema around edges of burn), treat for gram-positive organisms, (e.g., cefazolin or clindamycin). ▪ If patient develops invasive burn wound infection (signs: sepsis/septic shock, changes in color of wound, possible foul smell of wound), treat with broad-spectrum antibiotics.
Wounds (Role 1a)	▪ **Minimum** - Cover with clean sheet or dry gauze. Leave blisters intact. Avoid wet dressings. ▪ **Better** - Clean wounds by washing with any clean water (preferably with antibacterial soap if available), dress wounds with any available dressings; optimize wound and patient hygiene to the extent possible given the environment. ▪ **Best** - Clean wounds by scrubbing gently with gauze and clean water, followed by gauze dressing. ▪ DO NOT debride blisters until the patient has reached a facility with surgical capability. ▪ Every patient with facial burns should have a thorough eye exam. Conduct an eye exam early, before edema begins. ▪ If a corneal injury is identified, use a rigid shield to cover the eyes and apply ophthalmic erythromycin or neomycin ointment every 2 hours.
Wounds (Roles 1b/1c)	▪ **Better** - Clean wounds and **debride loose skin** by washing with any clean water (preferably with antibacterial soap if available), dress wounds with any available dressings; optimize wound and patient hygiene to the extent possible given the environment. ▪ **Best** - Clean wounds by scrubbing gently with gauze and **chlorhexidine gluconate solution (if available**) in clean water, apply topical antimicrobial cream followed by gauze dressing.

Monitoring	▪ Monitor vital signs and urine output (UOP) closely. ▪ **Minimum** - Use other measures If unable to measure UOP, adjust IV rate to maintain HR less than 140, palpable peripheral pulses, good capillary refill, intact mental status. ▪ **Better** - Capture all spontaneously voided urine in premade or improvised (i.e. Nalgene® water bottle) graduated cylinder; >180mL every 6 hours is adequate for adults. ▪ **Best** - Measure UOP with Foley catheter (burns to the penis are NOT a contraindication to catheter placement).

- Ensure all above interventions are completed by TCCC ASM, CLS and CMC personnel.
- Conduct inventory of all resources.
- Document all pertinent information on PCC Flowsheet (attached.)
- Additional interventions include:

Intervention	Paradigm
Airway (Roles 1a/1b/1c)	▪ **Minimum** - Allow casualty to maintain airway. Edema after burn injury causes most supraglottic airway devices such as LMAs to be inadequate. ▪ **Better** - Facial burns may be associated with inhalation injury. Aggressively monitor airway status and consider early surgical airway for respiratory distress or oxygen saturation and/or EtCO2 (purple-gold colorimetric device). ▪ **Best** - Indications for endotracheal intubation include: a comatose patient, symptomatic inhalation injury, deep facial burns, and burns over 40% TBSA. ▪ Utilize an EMMA (or other Capnography) EtCO2 device if possible. ▪ Use a large-bore endotracheal tube if inhalation injury is suspected (Size 8 ETT or larger is preferred for adults). ▪ Secure ETT with cotton umbilical ties (standard adhesive ETT holders do not work around burned skin). ▪ Frequently reassess position of the ETT during the acute resuscitation period as edema waves and wanes.

Legend:	TCCC - ASM	TCCC-CLS	TCCC-CMC	TCCC-CPP

*Link to Burn Wound Management in Prolonged Field Care, 13 Jan 2017 CPG [23]

Special Considerations in Burn Injuries

Chemical Burns

NOTE: Refer to the JTS Inhalation Injury and Toxic Industrial Chemical Exposure CPG for additional information.

- Expose body surfaces, brush off dry chemicals, and copiously irrigate with clean water. Large volume (>20L) serial irrigations may be needed to thoroughly cleanse the skin of residual agents. Do not attempt to neutralize any chemicals on the skin.
- Use personal protective equipment to minimize exposure of medical personnel to chemical agents.
- White phosphorous fragments ignite when exposed to air. Clothing may contain white phosphorous residue and should be removed. Fragments embedded in the skin and soft tissue should be irrigated out if possible or kept covered with soaking wet saline dressings or hydrogels.
- Seek early consultation from the USAISR Burn Center (DSN 312-429-2876 (BURN); Commercial (210) 916-2876 or (210) 222-2876; email usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil).

Electrical Burns

- TCCC ASM and CLS personnel should remove the patient from the electricity source while avoiding injury themselves.
- For cardiac arrest due to arrhythmia after electrical injury, follow advanced cardiac life support (ACLS) protocol and provide hemodynamic monitoring if spontaneous circulation returns.
- Small skin contact points (cutaneous burns) can hide extensive soft tissue damage.
- Observe the patient closely for clinical signs of compartment syndrome.
- Tissue that is obviously necrotic must be surgically debrided.

NOTE: Escharotomy, which relieves the tourniquet effect of circumferential burns, will not necessarily relieve elevated muscle compartment pressure due to myonecrosis associated with electrical injury; therefore, fasciotomy is usually required.

- Compartment syndrome and muscle injury may lead to rhabdomyolysis, causing pigmenturia and renal injury.
- Pigmenturia typically presents as red-brown urine. In patients with pigmenturia, fluid resuscitation requirements are much higher than those predicted for a similar-sized thermal burn.
- Isotonic fluid infusion should be adjusted to maintain UOP 75-100 mL/hr. in adult patients with pigmenturia.
- If the pigmenturia does not clear after several hours of resuscitation consider IV infusion of mannitol, 12.5 g per liter of lactated Ringer's solution, and/or sodium bicarbonate (150 mEq/L in D5W). These infusions may be given empirically; it is not necessary to monitor urinary pH. In patients receiving mannitol (an osmotic diuretic), close monitoring of intravascular status via CVP and other parameters is required.

- Seek early consultation from the USAISR Burn Center (DSN 312-429-2876 (BURN); Commercial (210) 916-2876 or (210) 222-2876; email usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil).

Pediatric Burn Injuries

- Children with acute burns over 15% of the body surface usually require a calculated resuscitation.
- Place a bladder catheter if available (size 6 Fr for infants and 8 Fr for most small children).
- The Modified Brooke formula (3 mL/kg/%TBSA LR or other isotonic fluid divided over 24 hours, with one-half given during the first 8 hours) is a reasonable starting point. This only provides a starting point for resuscitation, which must be adjusted based on UOP and other indicators of organ perfusion. Goal UOP for children is 0.5-1mL/kg/hr.
- Very young children do not have adequate glycogen stores to sustain themselves during resuscitation. Administer a maintenance rate of D5LR to children weighing < 20 kg. Utilize the 4-2-1 rule: 4ml/kg for the first 10kg + 2ml/kg 2nd 10kg + 1ml/kg over 20kg.
- In children with burns > 30% TBSA, early administration may reduce overall resuscitation volume.
- Monitor resuscitation in children, like adults, based on physical examination, input and output measurements, and analysis of laboratory data.
- The well-resuscitated child should have alert sensorium, palpable pulses, and warm distal extremities; urine should be glucose negative.
- Cellulitis is the most common infectious complication and usually presents within 5 days of injury. Prophylactic antibiotics do not diminish this risk and should not be used unless other injuries require antimicrobial coverage (penetrating injury or open fracture).
- Most antistreptococcal antibiotics such as penicillin are successful in eradicating infection. Initial parenteral administration is advised for most children presenting with fever or systemic toxicity.
- Nutrition is critical for pediatric burn patients. Nasogastric feeding may be started immediately at a low rate in hemodynamically stable patients and tolerance monitored. Start with a standard pediatric enteral formula (i.e. Pediasure) targeting 30-35 kcal/kg/day and 2g/kg/day of protein.
- Children may rapidly develop tolerance to analgesics and sedatives; dose escalation is commonly required. Ketamine and propofol are useful procedural adjuncts.
- When burned at a young age, many children will develop disabling contractures. These are often very amenable to correction which may be performed in theater with adequate staff and resources.
- Seek early consultation from the USAISR Burn Center (DSN 312-429-2876 (BURN); Commercial (210) 916-2876 or (210) 222-2876; email burntrauma.consult.army@mail.mil).
- Opportunities for pediatric surgical care provided by Non-Governmental Organizations (NGOs) may be the best option but require the coordinated efforts of the military, host nation, and NGOs.

Rule of Nines

On the DD Form 1380 the percentage of coverage on the casualty's body will need to be documented. The Rule of Nines will help with the estimation. The below figure shows the approximation for each area of the body:

- Eleven areas each have 9% body surface area (head, upper extremities, front and backs of lower extremities, and front and back of the torso having two 9% areas each).
- General guidelines are that the size of the palm of the hand represents approximately 1% of the burned area.
- When estimating, it is easiest to round up to the nearest 10.
- If half of the front or rear area is burned, the area would be half of the area value.
- For example, if half of the front upper/lower extremity is burned, it would be half of 9%, or 4.5%. If half of the front torso is burned, say either the upper or lower part of the front torso, then it would be half of 18%, or 9%.
- Remember, the higher the percentage burned, the higher the chance for hypothermia.
- For children, the percentage of BSA is calculated differently due to the distinctive proportion of major areas.

Figure 2. Adult Rule of Nines

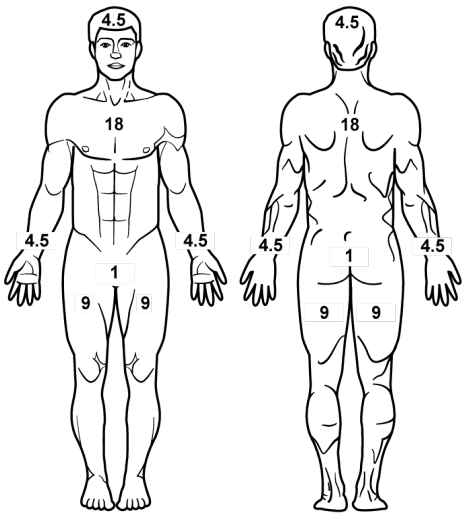

Figure 3. Pediatric Rule of Nines

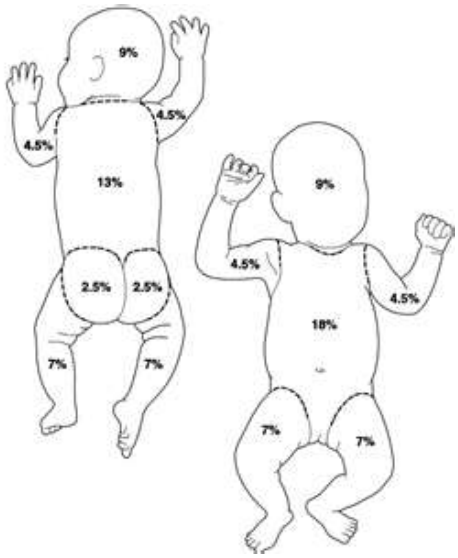

Link to Burn Wound Management in Prolonged Field Care, 13 January 2017 CPG [23]

LOGISTICS - PCC

Background

Reducing the time to required medical or surgical interventions prevents death in potentially survivable illness, injuries and wounds. When evacuation times are extended, en route care (ERC) capability must be adequately expanded to mitigate the delay. In January 2010, the J*oint Force Health Protection Joint Patient Movement Report stated* "the current success of the medical community is colored by the valiant ability to overcome deficiencies through 'just-in-time workarounds;' many systemic shortfalls are resolved and become transparent to patient outcomes. However, future operations may not tolerate current deficiencies." [24]

- Patient packaging is highly dependent upon the transportation or evacuation platform that is available
- If possible, rehearse patient packaging internally and with the external resources.
- Train with all possible assets, familiarizing them with standard operating procedures
- Ensure the patient is stable before initiating a critical patient transfer

Table 20. Logistics Interventions

Intervention	Paradigm
Prepare Documentation	▪ **Minimum** - TCCC Card - DA1380 ▪ **Better** - Prolonged Field Care Casualty Work Sheet ▪ **Best** - PCC Card with TCCC Card and any additional information, reference DA Form 4700 (SMOG 2021) for transport documentation standard.
Prepare Report	▪ Report should give highlights, expected course, and possible complications during transport. ▪ *The hand-off is the most dangerous time for the patient;* it is as important as treatments or medications. ▪ If it is rushed, things can easily be missed. ▪ Make sure you highlight non-obvious interventions and aspects of care (drugs given, repeat doses, etc.). ▪ **Minimum** - Verbal report describing the patient from head to toe with interventions or a SOAP note. ▪ **Better -** MIST (Mechanism, Interventions, Symptoms, Treatments) ▪ **Best** - MIST with appropriate SBAR (Situation, Background, Assessment, Recommendations) and pertinent labs and other diagnostic information
Prepare Medications	▪ **Minimum** - Prepare medication list with doses and time of next dose. ▪ **Better** - Above with additionally preparing next dose of medication for transport crew appropriately labeled. ▪ **Best** - Above with fresh IV fluids if indicated and fresh bags of drip medications with appropriate labeling and 72 hours of antibiotic for extended transports..
Hypothermia Management	▪ **Minimum** - Blankets ▪ **Better** - Sleep system and blankets. ▪ **Best** - HPMK with Ready Heat or Absorbent Patient Litter System (APLS). ▪ If possible, identify with tape the location of interventions or access points *on top of* hypothermia management to allow transport teams quick identification of location.

Intervention	Paradigm
Flight Stressor/ Altitude Management	▪ **Minimum** - Ear Protection and Eye Protection, if nothing available sunglasses and gauze may be used, if patient is sedated and intubated eyes can be taped shut. ▪ **Better** - Ear Pro and Eye Pro and blankets in all bony areas, Ear Protection and Eye Protection – foam ear plugs or actual hearing protection inserts, goggles. ▪ **Best** - Above with gastric tube (NG/OG) or chest tube for decompression, if indicated. Depending on altitude/platform, consider bleeding air of out bags of fluid.

Secure Interventions and Equipment	▪ **Minimum** - Tape:
	  ▪ Securely tape all interventions to include IVs, IOs, airway interventions, gastric tubes and TQs).
	  ▪ Oxygen tanks should be placed between the patients' legs and the monitor should be secured on the oxygen cylinder to prevent injury to the patient.
	  ▪ Pumps should be secured to the litter.
	▪ **Better** - Additional litter straps to secure equipment and extend the litter with back support as indicated for vented patients to prevent VAP
	▪ **Best** - Above. Use the Special Medical Emergency Evacuation Device (SMEED) to keep the monitor and other transport equipment off patient.

Prepare Dressings	▪ AE and Other MEDEVAC assets *do not routinely change dressings during transport*; therefore, ensure all dressings are changed, labeled, and secured before patient pick up. ▪ **Minimum** - Secure and reinforce dressings with tape, date, and time all dressings. ▪ **Better** - Change dressings within 24 hours of departure, secure as above. ▪ **Best** - Change and reinforce dressings within 4 hours of departure. Ensure additional Class VIII is available for any unforeseen issues in flight. ▪ **CAUTION -** Circumferential/constricting dressings MUST be limited/monitored due to swelling during prolonged aerial transport.
Secure the Patient	▪ **Minimum** - Litter with minimum of 2 litter straps. ▪ **Better** - Litter with padding (example: AE pad or Sleep Mat) with minimum of 3 litter straps. ▪ **Best -** Litter with padding and flight approved litter headrest with minimum of 3 litter straps. ▪ Additional litter straps can be used to secure patient or equipment.
Moving a Critical Care Patient	▪ **Minimum** - Two-person litter carry to CASEVAC/MEDEVAC platform. ▪ **Better** - Three-person litter carry to CASEVAC/MEDEVAC platform. ▪ **Best -** Four-person litter carry to CASEVAC/MEDEVAC platform.

APPENDIX C: MASCAL RESOURCES

Triage Guiding Principles

- Priorities change based on time from injury
- Activities in first hour are **CRITICAL**
- Don't waste time with formal triage tools
  Just extricate/stop threat, stop external bleeding, clear airway
- Transfusion and ventilator support within the first hour identify a resource-intensive patient
- Damage control surgery has little impact after the first hour

Figure 4. TRIAGE cheat cards START

<table>
<tr><td colspan="4">START TRIAGE: Assess, Treat (use bystanders)
When you have a color: STOP – TAG – MOVE ON</td></tr>
<tr><td rowspan="8">MINOR</td><td colspan="3">Move walking wounded</td></tr>
<tr><td rowspan="7">DECEASED</td><td colspan="2">No RESPIRATIONS after head tilt</td></tr>
<tr><td rowspan="6">IMMEDIATE</td><td>Breathing but UNCONSCIOUS</td></tr>
<tr><td>Respirations over 30</td></tr>
<tr><td>Perfusion capillary refill > 2 or NO RADIAL PULSE
Control bleeding</td></tr>
<tr><td>Mental Status: unable to follow simple commands</td></tr>
<tr><td rowspan="2">DELAYED</td><td>Otherwise</td></tr>
<tr><td>Remember:
Respirations – 30
Perfusion – 2
Mental Status – Can Do</td></tr>
</table>

Table 21. Triage Assessment

Each Patient Triage Assessment Should Be Complete in Less Than 60 Seconds	
Category	**Examples**
Category I: Immediate (red chemlite)	▪ (Any MARCH issue) ▪ Airway obstruction ▪ Flail/open chest wound ▪ Tension- Pneumothorax/hemothorax ▪ Massive hemorrhage ▪ 20-70% Burns ▪ Unstable Vital Signs ▪ Severe TBI (unconscious alive Pt)
Category II: Delayed (green chemlite)	▪ Open fractures w/PMS intact ▪ Soft tissue injuries ▪ Moderate TBI (stable vital signs) ▪ Open abdominal wounds
***Category III: Minimal (no chemlite) remain armed continue to engage**	▪ Minor abrasions, burns, sprains lacerations ▪ Moderate/Mild anxiety ▪ Fractures/dislocations w/PMS ▪ Mild TBI
****Category IV: Expectant or Hero (blue chemlite)**	▪ Massive head or spinal injury ▪ Third degree burns > 70% BSA ▪ Injuries incompatible with life

** In combat, it is assumed that minimals will continue to stay armed/engaged if no mental status altering pharmaceuticals are given for pain.*

**Expectant category is ONLY used in combat operations and/or when the requirements to adequately treat these patients exceed the available resources. In peacetime, it is generally assumed that all patients have a chance of survival.

Source: Special Operations Force Medic Handbooks (PJ, Ranger)

Triage Class 1 (MASCAL)

Adequate medics to treat critical patients and handle the rest

- Many casualties
- Threat controlled
- Resources not severely limited
- Medical personnel can arrive
- Evacuation possible

Table 22. Triage Class 1 Actions and Goals

<1 Hour After Injury	1 – 4 Hours After Injury	>4 Hours After Injury
Goals	**Goals**	**Goals**
▪ Eliminate Threat ▪ Establish CCP ▪ Blood transfusion within 30 minutes ▪ Evacuate to DCR/DCS within 1 hour	▪ DCR/DCS as soon as possible ▪ Use advanced resuscitation to "extend the Golden Hour"	Evacuate
Actions	**Actions**	**Actions**
▪ Stop external bleeding ▪ Clear airway ▪ Ensure ventilation ▪ Formal triage ▪ Transfuse	▪ MARCH PAWS ▪ Transfuse	Use prolonged care to optimize outcomes

Triage Class 2 (MASCAL)

Unable to manage the number of critical patients

- Numerous casualties or MASCAL (i.e. < 100 Casualties)
- Threat has been controlled or partially controlled
- Resources are very limited
- Medical personnel can arrive (may be delayed > 1 hour)
- Evacuation is possible (may be delayed > 1 hour)

Table 23. Triage Class 2 Actions and Goals

<1 Hour After Injury	1 – 4 Hours After Injury	>4 Hours After Injury
Goals	**Goals**	**Goals**
▪ Eliminate threat ▪ Get medical personnel on scene ▪ Begin evacuation of urgent but survivable patients	▪ Evacuate urgent and priority patients ▪ DCR/DCS as soon as possible	Evacuate remainder of patients
Actions	**Actions**	**Actions**
▪ Stop external bleed ▪ Clear airway ▪ Reserve intubation/transfusion ▪ CCP if able, otherwise get a count	▪ Formal triage ▪ MARCH PAWS if able ▪ Transfuse ▪ Establish CCP ▪ Utilize minimals/returns to duty	▪ Re-triage ▪ Complete MARCH PAWS ▪ Use prolonged care to optimize outcomes ▪ Wound/fracture management

Triage Class 3 (Ultra-MASCAL)

Absolutely overwhelming number of casualties

- Ultra-MASCAL (i.e. >100, possibly thousands of casualties)
- Threat is ongoing
- Resources are severely limited
- Medical personnel unable to arrive in < 1 Hour
- Evacuation not possible in < 1 Hour

Table 24. Triage Class 3 Actions and Goals

<1 Hour After Injury	1 – 4 hours After Injury	>4 Hours After Injury
Goals	**Goals**	**Goals**
▪ Respond to threat ▪ Self-aide, buddy care ▪ Separate ambulatory/ non-ambulatory	▪ Eliminate threat ▪ Get medical personnel on scene ▪ Begin evacuation	▪ Evacuate ▪ Distribute patients
Action	**Action**	**Action**
▪ Stop external bleed ▪ Clear airway ▪ Reverse intubation/ transfusion ▪ Get a count	▪ Stop external bleed ▪ Reserve intubation/transfusion ▪ Begin to establish CCPs ▪ Utilize minimals/return to Duty	▪ Formal triage ▪ Use prolonged care to optimize outcomes ▪ Wound/fracture management ▪ Utilize minimals/return to duty

APPENDIX E: TBI RESOURCES

Neurological Examination

MENTAL STATUS

Level of Consciousness: Note whether the patient is:

- Alert/responsive
- Not alert but arouses to verbal stimulation
- Not alert but responds to painful stimulation
- Unresponsive

Orientation: Assess the patient's ability to provide:

- Name
- Current location
- Current date
- Current situation (e.g., ask the patient what happened to him/her)

Language: Note the fluency and appropriateness of the patient's response to questions. Note patient's ability to follow commands when assessing other functions (e.g., smiling, grip strength, wiggling toes). Ask the patient to name a simple object (e.g., thumb, glove, watch).

Speech: Observe for evidence of slurred speech.

CRANIAL NERVES

All patients:

- Assess the pupillary response to light.
- Assess position of the eyes and note any movements (e.g., midline, gaze deviated left or right, nystagmus, eyes move together versus uncoupled movements).
- Noncomatose patient:
- Test sensation to light touch on both sides of the face.
- Ask patient to smile and raise eyebrows, and observe for symmetry.
- Ask the patient to say "Ahhh" and directly observe for symmetric palatal elevation.
- Comatose patient:
- Check corneal reflexes; stimulation should trigger eyelid closure.
- Observe for facial grimacing with painful stimuli.
- Note symmetry and strength.
- Directly stimulate the back of the throat and look for a gag, tearing, and/or cough.

MOTOR

Tone: Note whether resting tone is increased (i.e. spastic or rigid), normal, or decreased (flaccid).

Strength: Observe for spontaneous movement of extremities and note any asymmetry of movement (i.e. patient moves left side more than right side). Lift arms and legs, and note whether the limbs fall immediately, drift, or can be maintained against gravity. Push and pull against the upper and lower extremities and note any resistance given. Note any differences in resistance provided between the left and right sides.

(NOTE: it is often difficult to perform formal strength testing in TBI patients. Unless the patient is awake and cooperative, reliable strength testing is difficult.)

Involuntary movements: Note any involuntary movements (e.g., twitching, tremor, myoclonus) involving the face, arms, legs, or trunk.

SENSORY

If patient is not responsive to voice, test central pain and peripheral pain.

Central pain: Apply a sternal rub or supraorbital pressure, and note the response (e.g., extensor posturing, flexor posturing, localization).

Peripheral pain: Apply nail bed pressure or take muscle between the fingers, compress, and rotate the wrist (do not pinch the skin). Muscle in the axillary region and inner thigh is recommended. Apply similar stimulus to all four limbs and note the response (e.g., extensor posturing, flexor posturing, withdrawal, localization).

NOTE: In an awake and cooperative patient, testing light touch is recommended. It is unnecessary to apply painful stimuli to an awake and cooperative patient.

GAIT

If the patient is able to walk, observe his/her casual gait and note any instability, drift, sway, and so forth.

Ultrasonic Assessment of Optic Nerve Sheath Diameter

If a patient is unconscious (i.e. does not follow commands or open eyes spontaneously), they may have elevated ICP. There is no reliable test for elevated ICP available outside of a hospital; however, optic nerve sheath diameter (ONSD) measurement is a rapid, safe, and easy-to-perform ultrasonographic assessment that may help identify elevated ICP when more definitive monitoring devices are not available.

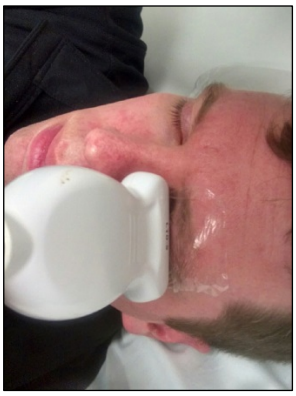
- The optic nerve sheath directly communicates with the intracranial subarachnoid space. Increased ICP, therefore, displaces cerebrospinal fluid along this pathway. Normal ONSD is 4.1–5.9mm.[30]
- A 10–5-MHz linear ultrasound probe can be used to obtain ONSDs. ONSD is measured from one side of the optic nerve sheath to the other at a distance of 3mm behind the eye immediately below the sclera.[31]
- In general, ONSDs >5.2mm should raise concern for clinically significant elevations in ICP in unconscious TBI patients.[5,32] The ONSD can vary significantly in normal individuals, so one single measurement may not be helpful; however, repeated measurements that detect gradual increases in ONSD over time may be more useful than a single measurement.
- ONSD changes rapidly when the ICP changes, so it can be measured frequently.[33] If ONSD is used, it is best to check hourly along with the neurologic examination.

Technique

1. Check to make sure there is no eye injury. A penetrating injury to the eyeball is an absolute contraindication to ultrasound because it puts pressure on the eye.
2. Ensure the head and neck are in a midline position. Gentle sedation and/or analgesia may be necessary to obtain accurate measurements.
3. Ensure the eyelids are closed.
4. If available, place a thin, transparent film (e.g., Tegaderm; 3M, http://www.3m.com) over the closed eyelids.
5. Apply a small amount of ultrasound gel to closed eyelid.
6. Place the 10(–5) MHz linear probe over the eyelid. The probe should be applied in a horizontal orientation (Figure 1) with as little pressure as possible applied to the globe.
7. Manipulate the probe until the nerve and nerve sheath are visible at the bottom of screen. An example of a proper ultrasonagraphic image of the optic nerve sheath can be seen in Figure 2.
8. Once the optic nerve sheath is visualized, freeze the image on the screen.
9. Using the device's measuring tool, measure 3mm back from the optic disc and then obtain a second measurement perpendicular to the first. The second measurement should cover the horizontal width of the optic nerve sheath (Figure 2). An abnormal ONSD is shown in Figure 3.
10. Repeat the previous sequence in the opposite eye. Annotate both ONSDs on the PFC Casualty Card.
11. ONSDs should be obtained, when possible, at regular intervals to help assess changes in ICP, particularly when the neurologic examination is poor and/or unreliable (i.e. with sedation). Serial measurements with progressive diameter enlargement and/or asymmetry in ONSDs should be considered indicative of worsening intracranial hypertension.

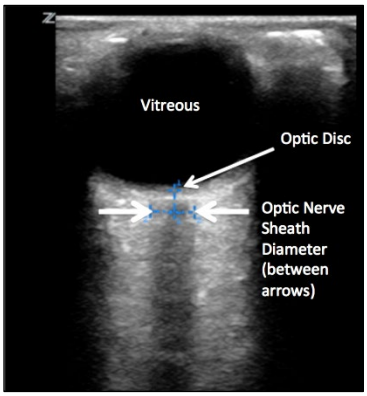
CAUTION: ONSD measurements are contraindicated in eye injuries. NEVER apply pressure to an injured eye.

Figure 1. *Appropriate placement of the linear probe.*



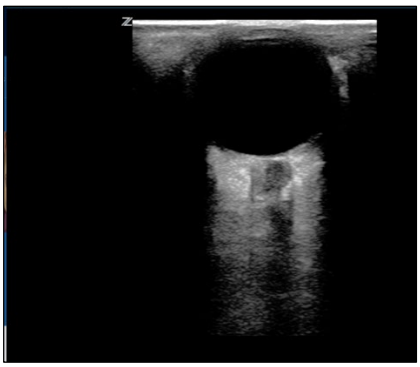
Ultrasound gel is placed over a closed eyelid and the probe placed horizontally over the eyelid, applying as little pressure to the globe as possible. If available, Tegaderm or other thin covering (e.g., Latex glove) should be placed over a closed eyelid for further protection.

Figure 2 *An ultrasonographic view of a normal eye and optic nerve sheath.*



To measure ONSD, apply the ultrasound measuring device to the optic disc and measure back 3mm along the length of the optic nerve. A second, perpendicular measurement is obtained at the previously measured point that spans the horizontal width of the optic nerve sheath. In this image, ONSD was determined to be 5.1mm, a normal value.

Figure 3*. Ultrasound image of the right optic nerve sheath of a 61-year-old man with a traumatic subdural hematoma.*



The optic nerve sheath measured 6.8mm in diameter. Elevated ICP was subsequently confirmed (26mmHg) after the placement of an ICP bolt monitor.

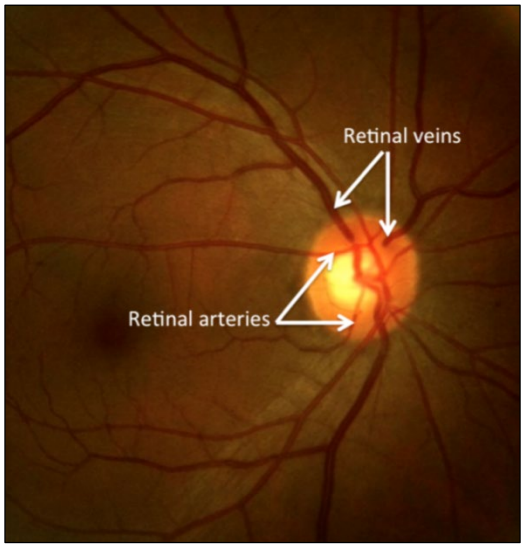
Spontaneous Venous Pulsations

- Spontaneous venous pulsations (SVPs) are subtle, rhythmic variations in retinal vein caliber on the optic disc and have an association with ICP.
- It is difficult to see SVPs without advanced equipment; however, if a handheld ophthalmoscope is available, it is worth an attempt to visualize the retinal veins.
- Don't worry if you cannot see SVPs; this may actually be normal. However, if you do see them, it is very reassuring that ICP is normal.[10]
- If SVPs are initially present and can no longer be seen on subsequent examinations, the provider should be concerned for increasing ICP.

Technique

1. Gently lift the eyelid until the pupil is in view.
2. Using a handheld ophthalmoscope, the provider should maneuver himself or herself to a position where the optic disc can be visualized.
3. Identify the retinal veins as they emerge from the optic disc. Retinal veins are typically slightly larger and darker than retinal arteries. Figure at right demonstrates the typical appearance of the retina.
4. Observe the retinal veins for pulsations. Note the presence or absence of spontaneous venous pulsations
5. Repeat the step 1–4 sequence in the contralateral eye.

Figure 6. Typical appearance of a healthy retina.



The retinal vessels can be seen emerging from the optic disc. Retinal veins can be identified by their slightly larger, thicker size and darker color. Retinal arteries are small, thin, and lighter in color than retinal veins.

Glasgow Coma Scale

TBI severity classification using the GCS score:

- Mild: 13–15
- Moderate: 9–12
- Severe: 3–8

Eye Opening	Verbal Response	Motor Response
4 – Spontaneous 3 – To verbal command 2 – To painful stimuli 1 – No response	5 – Oriented 4 – Confused 3 – Inappropriate words 2 – Incomprehensible sounds 1 – No response	6 – Obeys commands 5 – Localizes to painful stimuli 4 – Withdraws from pain 3 – Flexion to pain 2 – Extension to pain 1 – No response

Richmond Agitation Sedation Scale (RASS)

Score	Term	Description	
+4	Combative	Overtly combative, violent, immediate danger to staff.	
+3	Very Agitated	Pulls or removes tube(s) or catheter(s); aggressive.	
+2	Agitated	Frequent non-purposeful movement, fights ventilator.	
+1	Restless	Anxious but movements not aggressive vigorous.	
0	Alert, Calm		
-1	Drowsy	Not fully alert, but has sustained awakening (eye-opening/eye contact) to voice (≥10 seconds).	Verbal Stimulation
-2	Light Sedation	Briefly awakens with eye contact to voice (<10 seconds).	
-3	Moderate Sedation	Movement or eye opening to voice (but no eye contact).	
-4	Deep Sedation	No response to voice, but movement or eye opening to physical stimulation.	Physical Stimulation
-5	Unarousable	No response to voice or physical stimulation.	

Procedure for RASS Assessment	
1. Observe patient: Patient is alert, restless, or agitated.	Score 0 to+4
2. If not alert, state patient's name and say to open eyes and look at speaker	
- Patient awakens with sustained eye opening and eye contact.	Score -1
- Patient awakens with eye opening and eye contact, but not sustained.	Score -2
- Patient has any movement in response to voice but no eye contact.	Score -3
3. When no response to verbal stimulation, physically stimulate patient by shaking shoulder and/or rubbing sternum.	
- Patient has any movement to physical stimulation.	Score -4
- Patient has no response to any stimulation.	Score -5

Signs and Symptoms of Elevated Intracranial Pressure

- GCS<8 and suspected TBI
- Rapid decline in mental status
- Fixed dilated pupils(s)
- Cushing's triad hemodynamics (hypertension, bradycardia, altered respirations)
- Motor posturing (unilateral or bilateral)
- Penetrating brain injury and GCS <15
- Open skull fracture

Hypertonic Saline (HTS) Protocol (goal Na 140-165 meq/L)

- 3% HTS: 250-500 cc bolus, then 50 ml/hr infusion, rebolus as needed for clinical signs
- 7.5% HTS: decrease above doses by 50%
- 23.4%: dilute to 3% and use as above. If unable to dilute, can be given as 30 ml bolus and re-dose as needed.
- Central venous line (CVL) preferred for 3% (can be given initially via peripheral IV/IO)
- CVL **REQUIRED** for 7.5% or higher concentration

APPENDIX F: LOGISTICS RESOURCES

Prolonged Field Care – Patient Packaging, 11 Aug 2021

Patient packaging is highly dependent upon the Casualty Evacuation (CASEVAC) / Medical Evacuation (MEDEVAC) platform that is operationally available. If possible, rehearse patient packaging internally and with the external resources. Train with MEDEVAC assets understand transporting teams' standard operating procedures in order to best prepare the patient for transport. (Example some teams want to secure the patient and interventions themselves while others may be okay with a fully wrapped patient).

Ensure the patient is stable before initiating a critical patient transfer. For POI/unstable patients ensure the appropriate transport team (MEDEVAC with en route critical care nurse or advanced provider). Interfacility transfers should meet the following minimum:

1. Hemorrhage control
2. Resuscitation adequate (SBP 70-80 mmHg, MAP >60, or UOP >0.5ml/kg/hr)
3. Initial post-op recovery as indicated
4. Stabilization of fractures

Prepare Documentation

- **Good**: TCCC Card - DA1380
- **Better**: Prolonged Field Care Casualty Work Sheet
- **Best**: PFC Card with TCCC Card and any additional information, reference DA Form 4700 (SMOG 2021) for transport documentation standard

*preference: secure to patient strip of 3in Tape with medications administered attached to blanket or HPMK

Prepare Report

Report should give highlights, expected course, and possible complications during transport. The hand-off is the most dangerous time for the patient it is as important as treatments or medications. If it is rushed things can easily be missed.

- **Good**: Verbal report describing the patient from head to toe with a SOAP note.
- **Best**: MIST (Mechanism, Interventions, Symptoms, Treatments)
- **Better**: MIST with appropriate SBAR (Situation, Background, Assessment, Recommendations) and pertinent labs and other diagnostic information

Prepare Medications

- **Good:** Prepare medication list with doses and time of next dose
- **Better**: Above with additionally preparing next dose of medication for transport crew appropriately labeled.
- **Best**: Above with fresh IV fluids if indicated and fresh bags of drip medications with appropriate labeling and 72 hours of antibiotic for extended transports.

Hypothermia Management

- **Good**: Blankets
- **Better**: Sleep system and blankets
- **Best**: HPMK with Ready Heat or Absorbent Patient Litter System (APLS)

Flight Stressor/ Altitude Management

- **Good**: Ear Protection and Eye Protection, if nothing available sunglasses and gauze may be used, if patient is sedated and intubated eyes can be taped shut
- **Better**: Ear Pro and Eye Pro and blankets in all bony areas, Ear Protection and Eye Protection – foamies or actual hearing protection inserts, goggles
- **Best**: Above with gastric tube (NG/OG) or chest tube for decompression, if indicated. Depending on altitude/platform, consider bleeding air of out bags of fluid.

Secure Interventions and Equipment

- **Good**: Tape (securely tape all interventions to include IVs, IOs, Airway interventions, Gastric Tubes and TQs). Oxygen tanks should be placed between the patients legs and the monitor should be secured on the oxygen cylinder to prevent injury to the patient. Pumps should be secured to the litter
- **Better**: Additional litter straps to secure equipment and extend the litter with back support as indicated for vented patients to prevent VAP.
- **Best**: Above and use the SMEED to keep the monitor and other transport equipment off patient

*if possible, identify with tape the location of interventions or access points on top of hypothermia management to allow transport teams quick identification of location.

Prepare Dressings

Air Evacuation and other MEDEVAC assets do not routinely change dressings during transport; therefore, ensure all dressings are changed, labeled, and secured before patient pick up

- **Good**: Secure and reinforce dressings with tape, date, and time all dressings.
- **Better**: Change dressings within 24 hours of departure, secure as above.
- **Best**: Change and reinforce dressings within 4 hours of departure. Ensure additional Class VIII is available for any unforeseen issues in flight.

Secure the Patient

- **Good**: Litter with minimum of 2 litter straps
- **Better**: Litter with padding (example: AE pad or Sleep Mat) with minimum of 3 litter straps
- **Best**: Litter with padding and flight approved litter headrest with minimum of 3 litter straps (additional litter straps can be used to secure patient or equipment)

Moving a Critical Care Patient

- **Good**: Two person little carry to CASEVAC/MEDEVAC platform
- **Better**: Three person little carry on a rickshaw to CASEVAC/MEDEVAC platform
- **Best**: Four person little carry on a rickshaw to CASEVAC/MEDEVAC platform

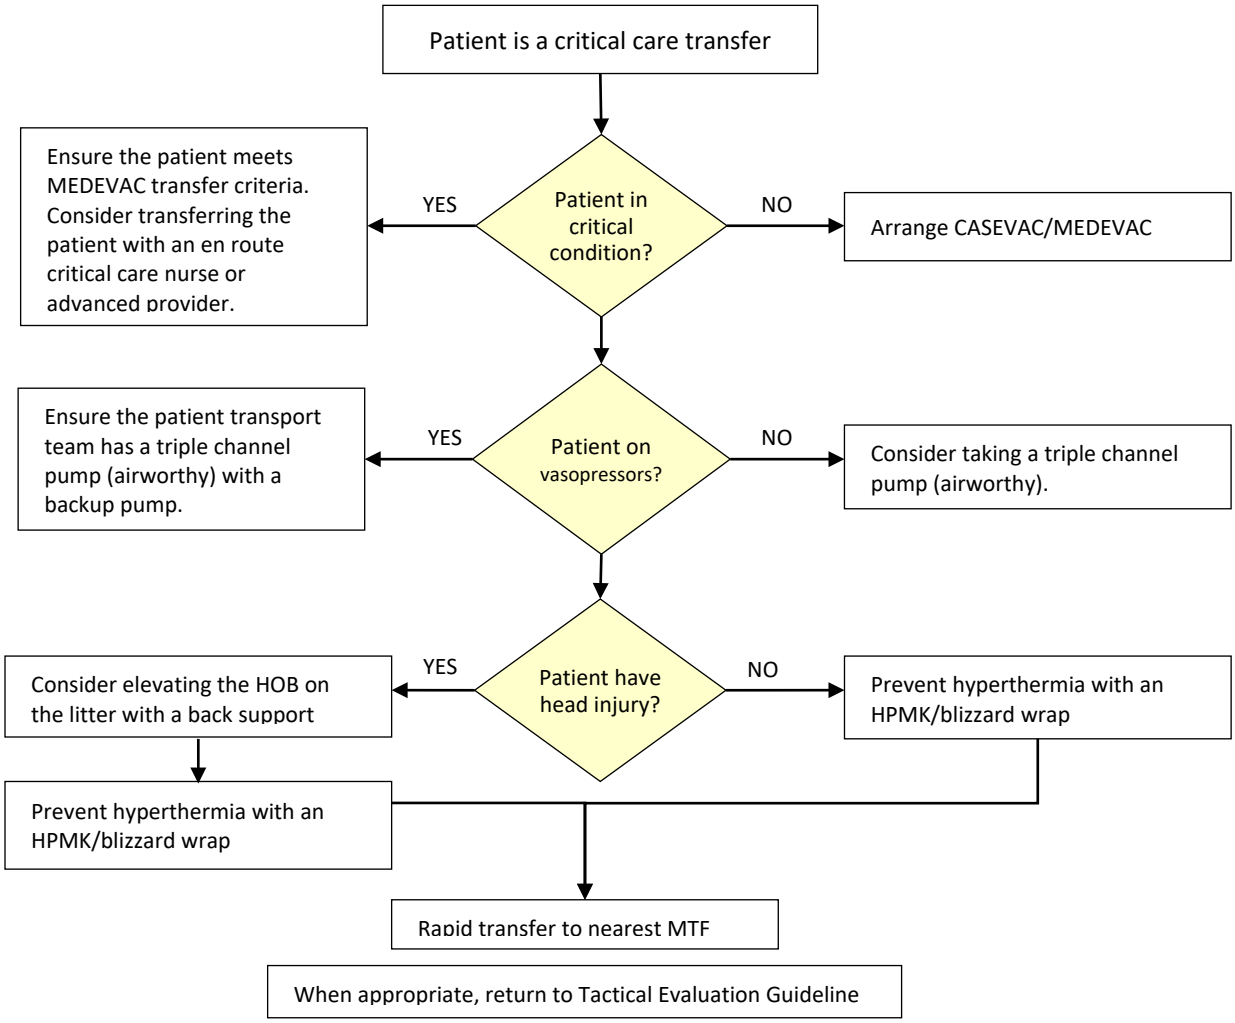
Prolonged Casualty Care Patient Packaging Flowchart

Equipment:

- Litter with at least three litter straps
- Three channel IV pump (airworthy)
- Cardiac monitor and cables
- Suction Device

Possible Complications:

- Inadequate medications
- Injuries not addressed before transport
- Inexperienced provider on flight
- Equipment issues



Patient is a critical care transfer
Patient in critical condition?
YES
Ensure the patient meets MEDEVAC transfer criteria. Consider transferring the patient with an en route critical care nurse or advanced provider.
NO
Arrange CASEVAC/MEDEVAC
Patient on vasopressors?
YES
Ensure the patient transport team has a triple channel pump (airworthy) with a backup pump.
NO
Consider taking a triple channel pump (airworthy).
Patient have head injury?
YES
Consider elevating the HOB on the litter with a back support
Prevent hyperthermia with an HPMK/blizzard wrap
NO
Prevent hyperthermia with an HPMK/blizzard wrap
Rapid transfer to nearest MTF
When appropriate, return to Tactical Evaluation Guideline

Pearls:

- Document all times – TCCC Card or DA4700.
- Assist Ensure the patient is stable before initiating a critical patient transfer.
- POI/unstable patients ensure the appropriate transport team (MEDEVAC W/ECCN or Advanced provider)
- Interfacility transfers should meet the following minimum:
  - Hemorrhage control
  - Resuscitation adequate (SBP 70-80 mmHg, MAP >60, or UOP >0.5ml/kg/hr)
  - Initial post-op recovery as indicated
  - Stabilization of fractures

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Radiology: Imaging Trauma Patients in a Deployed Setting (CPG ID: 01)

Provides general imaging guidelines for Radiologist and Emergency Providers when performing trauma patient assessment in a deployed setting.

BACKGROUND

Medical imaging plays a critical role in the rapid diagnosis, effective triage, and management of complex poly-trauma patients. High quality medical imaging can be accomplished successfully in a deployed or wartime setting. Due to advances in aggressive resuscitation techniques and the speed of the latest generation Computed Tomography (CT) scanners (64-detector and beyond), rapid trauma scans utilizing CT and Ultrasound (US) imaging can routinely be performed prior to taking the patient to the operating room potentially providing the trauma team with lifesaving information. This Clinical Practice Guideline (CPG) provides an overview of the imaging modalities available in austere settings, the equipment required, and the role that each plays in triaging and diagnosis of the acutely injured poly-trauma patients.

Given the catastrophic injuries sustained by high-energy mechanisms, including high velocity ballistic trauma and blast injuries often seen during the current conflict, rapid diagnosis and treatment is required to optimally treat these critically injured patients. Advances in aggressive resuscitation techniques and the speed of the latest generation Computed Tomography (CT) scanners (64-detector and beyond), rapid trauma scans utilizing CT and Ultrasound (US) imaging routinely allows for imaging to be performed prior to taking the patient to the operating room potentially providing the trauma team with lifesaving information.

Imaging has become a critical component of the care of any patient in the age of modern medicine. The goal of this CPG is to provide guidelines and recommendations for the optimum integration of high quality diagnostic imaging into the treatment and management of casualties with multiple mechanisms of traumatic injuries and how to facilitate the transfer of this information with the patient across the continuum of care.

IMAGING EVALUATION

RADIOGRAPHS

The initial radiographic evaluation of a trauma patient begins with supine Anterior-Posterior (AP) chest and pelvis radiographs taken in the trauma bay usually with a portable x-ray machine. The initial focus being major cardiopulmonary injury and fracture dislocations of the pelvis, the latter can be an indicator of life-threatening internal hemorrhage and/or need for pelvic stabilization.

Fragments

Radiographs can easily demonstrate metallic fragments common in military specific trauma that can be helpful in determining potential sites of injury and injury tracts.

Cervical Spine

Cervical spine radiographic evaluation has been largely replaced by CT and should only be performed when a CT is unavailable. Refer to the JTS CPG, *Cervical and Thoracolumbar Spine Injury Evaluation, Transport, and Surgery in the Deployed Setting*, for further guidance.[1,2]

Extremity Injuries

If extremity injury is suspected, radiographs can be obtained; however, these can be time-consuming and should not delay more diagnostic imaging with CT, if available (Role 3 and above). Additionally with CT, extremity osseous and soft tissue injuries can be easily identified with the added benefit of a lower extremity angiogram as well. See Trauma CT Scan section below.[3]

Retrograde Urethrogram

When there is a clinical suspicion of possible urethral injury, which can occur with significant pelvic fractures or penetrating perineal injury, a retrograde urethrogram may be helpful to further characterize the injury. One field expedient method uses the portable x-ray machine with a single oblique AP scout image of the pelvis. 10cc of contrast is injected into the tip of the urethra through a Foley catheter. While injecting additional contrast through the catheter an image of the pelvis/urethra is obtained in the same slight AP oblique position. This image is typically obtained at the end of an injection of 17-20 cc of IV contrast but prior to the completion of the injection to insure full luminal distention with contrast.

Equipment

A variety of portable x-ray units are utilized in theater at Role 2 and Role 3 facilities. Many of the portable units, especially at the Role 2, have limited ability to penetrate (limited range of kVp and mAs) soft tissues. Obtaining lateral views generally requires penetrating a greater thickness of soft tissue, particularly in large patients, and often produces very limited quality images. AP projection images should be adequate on most portable units, but will rely upon the x-ray technician to optimize technique to maximize image quality.

Radiation Safety

Members of the trauma team should have lead aprons and thyroid shields available near the trauma bay. In ideal situations, trauma team members will don the lead shielding beneath other personal protective equipment prior to patient arrival. Distance is also protective from radiation exposure. If feasible based on the patient's condition, any personnel without lead shielding should move a short distance (recommended minimal distance 6 feet) away from the x-ray unit. Cross table lateral images produce a much higher level of radiation exposure to personnel in the trauma bay and nearby areas and should only be obtained when absolutely necessary.

Radiation certainly remains a concern during the performance of all imaging particularly with CT. The radiologist should carefully monitor mAs and kVp settings such that dose is minimized while achieving sufficient diagnostic image quality.

FOCUSED ABDOMINAL SONOGRAPHIC ASSESSMENT FOR TRAUMA (FAST) EXAMINATION

While the FAST scan has been validated only in hemodynamically unstable blunt trauma patients, it has become a standard tool in the trauma bay and Emergency Department (ED) in most trauma patients.[4] It is now considered an adjunct to the primary survey in Advanced Trauma Life Support (ATLS) guidelines, ninth edition.[5] It has also come into use for hemodynamically stable patients and penetrating trauma in the deployed setting where CT scans are not readily available. If positive, these scans provide quick information that can aid trauma surgeons in triaging patients, either to the Operating Room (OR) or to further imaging. FAST in combat trauma

has a sensitivity of only 56% and specificity of 98%.[6] Routine use of the FAST in trauma patients allows for a consistent evaluation strategy while maintaining the skills of providers. A negative FAST cannot be relied upon to rule out injury, especially in penetrating trauma.

Diagnostic Peritoneal Lavage (DPL)

In the absence of a CT scanner, DPL should be considered in determining need for laparotomy in trauma patients. It has largely been supplanted by the FAST exam (and is considered an optional skill in the current edition of ATLS). DPL remains the most sensitive test for hollow viscus injury and mesenteric injury, and retains its usefulness in the unstable patient with a negative or equivocal FAST exam. DPL is 100% accurate for intrabdominal injury in these patients.[7] One must consider the additional time that this diagnostic test may require, and should not delay immediate surgical intervention in patients that have mechanisms concerning for intra-abdominal trauma and remain unstable despite resuscitative measures.[8]

Role of the Radiologist

At the Role 3, properly trained providers including radiologists, surgeons and emergency physicians, can perform and interpret FAST scans in the ED on a hand held portable US device. The utility of radiologists performing the exams would be to free up emergency providers and surgeons to either perform other assessments or interventions, or care for additional patients in the trauma bays. While in the trauma bay, the radiologist would also be available to provide preliminary interpretations of the portable chest x-ray/pelvis exams on the digital portable machines. However, once CT scans begin to be obtained on the trauma patients, the emergency physicians and surgeons would primarily perform the FAST scans and interpret plain radiographs at the bedside.

Equipment

The examination is performed with a portable hand-held machine most commonly using a standard 3-7 MHz curved array US probe. A phased array probe is also acceptable, and occasionally is preferred if cardiac or pulmonary imaging is necessary. Real-time imaging is performed without the necessity of saving static images.

Standard Examination

The standard FAST examination is focused on evaluating for the presence of free intraperitoneal fluid in:

1. The right upper quadrant between the liver and kidney,
2. The left upper quadrant between the spleen and kidney, and;
3. The pelvis at the level of the bladder.
4. An evaluation for cardiac activity and hemopericardium/tamponade should also be performed by placing the probe in the subxiphoid location and aiming towards the patients left shoulder.[4]

Additional Examinations

The cardiac portion of the exam can rapidly identify cardiac injury, evaluate cardiac function and give information about the success of resuscitation.[9] In the case of massive exsanguination; the examination should be rechecked for free fluid after blood is given. A clot identified within a ventricle indicates prolonged asystole and may aid in the decision to terminate efforts. Pneumothorax or hemothorax may also be identified by placing the probe along the chest wall and looking for the presence of lung sliding. Loss of sliding implies the possible presence of a pneumothorax.[10]

TRAUMA CT SCAN

If at all possible given the patient's clinical stability, a trauma CT can be performed before going to OR. Often indications for surgical intervention are already present; however the CT scan can provide additional information to the surgeon, identifying unsuspected and potentially clinically significant injuries. Given the relatively small footprint of most Role 3 facilities the patient can be taken to the OR immediately following the acquisition of the CT scan, with the radiologist providing the pertinent findings to surgeons while in the OR. For clinically unstable patients, this trauma CT can be obtained after continued resuscitation and surgical intervention in the OR.[11]

CT Protocol (Adult)

. Initial acquisition includes non-contrast CT through head and face (to include the entire mandible), at 1 mm axial slice thickness which allows for isotropic sagittal and coronal reformatted images. This scan is followed by a contrast enhanced CT from the level of the circle of Willis through the bottom of the pelvis. Alternatively in the setting of significant lower extremity trauma such as dismounted complex blast injury, the scan can be performed through the lower extremities (default through the feet) allowing evaluation of skeletal and vascular injury of the lower extremities. A discussion with the trauma team should be performed prior to the scan to establish the inferior extent of the scan coverage. Of course, additional information including long bone fractures and metallic fragments can be seen on the scout image, which may alter the scan coverage to include those areas. Some difficulties may arise if the patient is tall and the CT gantry movement does not allow coverage through the lower extremities, however this can be ameliorated by scanning from the head to as low as possible, then either physically sliding the patient up on the gantry or rotating them 180 degrees on the gantry table and scanning through the remainder of the legs.[11-13] See Appendix A for more information.

CT Review

3D workstations are a required resource in any civilian trauma center and are a required resource for any Role 3 where major casualties are expected. These workstations allow the radiologist a rapid overview of injuries and ability to zoom into abnormalities. Additionally these powerful workstations allow for rapid creation of detailed 3D shaded surface and multiplanar reconstructions that facilitate a broad overview of numerous soft tissue and osseous injuries at different locations and accentuate the location of fragments. Utilizing these shaded bone or skin surface and Multiplanar Reconstruction (MPR) images can be very helpful for injury tract analysis. The workstation also enables focused arterial vascular analysis, thus supporting early identification of more subtle vascular injuries that can have a significant clinical impact on patient morbidity and mortality.[13] In mass casualty situations, a modified workflow may be necessary. The performance of preliminary readings or "wet reads" may be required, especially when there is a sole radiologist present.

IV Access for CT

18g antecubital IV is typically desired – if placed on a medical evacuation platform prior to arrival, the cannula must be thoroughly rechecked/flushed to ensure function and avoid contrast extravasation. More distal upper extremity IVs should typically not be used due to the risk of extravasation and compartment syndrome. A central line can be used for contrast power injection. A large lumen resuscitation catheter such as those utilized for the rapid infusion device (normally rated up to 9cc/sec) can usually handle contrast injection.[14] Ensure that the correct size catheter lumen is utilized for the power injection as the catheter will often have various sized lumens. The largest lumen of catheter would be the best to handle the power injection. Of course, should the rapid infusion device be used to infuse fluid/blood products at the same time, it should be turned off during the injection to avoid dilution of the contrast with the instillate. Current intraosseous needles should not be used for contrast administration. Though a few case reports of individual patients undergoing CT examination with contrast injection through IO needles have been published, larger studies in trauma patients are needed to establish efficacy, adverse effects, and bolus timing modifications.

CT Contrast Injection

The goal of the injection is to provide concurrent solid organ enhancement, arterial enhancement, and pulmonary arterial. Typical doses are approximately 150 cc of Isovue 300 or 340 contrasts utilizing a dual phase injection – 80cc at 1.4 cc/sec, followed immediately by 70cc at 3.5 cc/sec for the pan scan. The scan is started 2-3 seconds before the completion of the contrast injection to maximize pulmonary arterial filling. For pediatric injection volume and rates by weight, see Appendix B.

Rectal Contrast

This can be helpful when evaluating penetrating flank injuries or possible rectal involvement below the peritoneal reflection from pelvic injuries. One may utilize 1L of saline/water with the addition of 1 bottle (50ml) of IV contrast. A Foley catheter is used to cannulate the rectum and the balloon is instilled with saline. In the setting of significant rectal or perineal trauma the surgeon may need to place the Foley catheter in the rectum.[16]

Delayed Images

Routinely performed for further evaluation of identified solid organ injury, identify active extravasation or pseudoaneurysm formation, which can aid surgeons in grading the solid organ injury. Additionally, contrast excretion within the ureters and subsequently into the bladder can also aid in diagnosis of injuries to these structures.

CT Cystogram

50 cc of IV contrast diluted into 500 cc of saline is infused through the indwelling urinary catheter. A minimum of 300 cc and up to 500 cc of this dilute contrast material should be infused to provide adequate evaluation of the integrity of the bladder wall. The catheter is then clamped for the CT examination. This type of exam is performed following the routine trauma CT with 1mm thick images acquired through the pelvis with the bladder filled. If necessary, additional axial imaging of the bladder can be performed following the drainage of the contrast to detect more subtle extraperitoneal bladder injuries which may be obscured by the distended bladder.[17]

CT Language Settings

Become familiar with the languages available/preloaded on the scanner for breathing instructions, which often include: English, French, Spanish, Japanese, and Chinese. Using interpreters available in your facility, record the same instructions in commonly encountered languages of coalition partners and host-nation patients (e.g., Arabic, Pashtun, Dari, Farsi, Georgian, Italian, Danish, Estonian, etc.). Ensure to select the correct language at the time of scan setup for each patient. Using these instructions will improve image quality for conscious patients.

MILITARY WORKING DOGS (MWD)

Given the nature of military operations in the current conflict, MWDs have sustained similar injuries to dismounted soldiers and will need CT trauma scans as well.[18] These examinations will typically be performed in consultation with veterinarians who will sedate the dog as necessary for the scan. However in an emergency situation, it may be necessary for the radiologist to perform the scan. Given this eventuality, prior coordination between the radiologist and veterinarian is essential. Utilize a scanning protocol based on the pediatric settings to include the doses of and rates of contrast administration. Refer to the JTS CPG, *Clinical Management of Military Working Dog*[18] and Appendix B for further details.

IMAGE TRANSFER

All patients evacuated through casualty evacuation should have images sent electronically ahead of time as well as have a CD created to send with the patient as a backup. Although at times trauma patient's true name may not be known during the initial evaluation, it should be stressed that usually it becomes known sometime soon thereafter. Ensuring the patient's information is updated with the real name rather than a local hospital's trauma name will ensure those studies are available for review through the health care evacuation system.

MRI

While MRI has been deployed to theater in the past, its utility in the acute management of combat trauma has not been established. Refer to the JTS CPG *Use of MRI in Management of mTBI in the Deployed Setting*.[19]

PERFORMANCE IMPROVEMENT (PI) MONITORING

INTENT (EXPECTED OUTCOMES)

All trauma patients arriving at a Role 3 hospital will receive proper and expeditious radiologic screening of injuries.

PERFORMANCE/ADHERENCE MEASURES

Identify missed injuries with appropriate radiographic imaging and/or reading.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- Theater Image Repository

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: DETECTOR TRAUMA CT PROTOCOL

TRAUMA CT PROTOCOL

1. Unenhanced spiral brain 1.25mm (bone and soft tissue algorithm); 5mm reconstructions immediately available for review.
2. Circle of Willis to symphysis (bone and soft tissue algorithms).
    - 150ml biphasic contrast injection – initial 65ml at 2ml/sec then 85 ml at 3.5ml/sec Scan starts at 60 sec
    - This gives both portal venous enhancement with good arterial contrast at the same time and the scan can be carried on down to the legs/feet is necessary. The cervical contrast has been very useful both for penetrating injury and for spinal injury/vertebral artery injury.
3. The use of delayed scans limited to specific cases at the request of the radiologist.

64 DETECTOR TRAUMA CT PROTOCOL

1. Unenhanced helical brain 1.25mm (bone and soft tissue algorithm); 3mm reconstructions immediately available for review.
2. Circle of Willis to symphysis 1.25mm (bone and soft tissue algorithms); 3 to 5mm reconstructions immediately available for review.
    - 150mL biphasic contrast injection – initial 80cc at 1.4 cc/sec then 70cc at 3.5 cc/sec
    - Scan starts 3 sec before the completion of the contrast injection.
3. This gives both portal venous enhancement with good arterial contrast at the same time and the scan can be carried on down to the legs/feet is necessary. The cervical contrast has been very useful both for penetrating injury and for spinal injury/vertebral artery injury.
4. The use of delayed scans limited to specific cases at the request of the radiologist.

16 DETECTOR TRAUMA CT PROTOCOL

1. Unenhanced helical brain 1.5mm (bone and soft tissue algorithm); 3mm reconstructions immediately available for review.
2. Circle of Willis to symphysis 1.5mm (bone and soft tissue algorithms); 5mm reconstructions immediately available for review.
    - Arterial phase imaging – 150mL single arterial phase contrast injection at 3.5 cc/sec.
    - Automatically triggered with a threshold of 100 HU at the level of the aortic arch.
3. The arterial phase imaging alone is preferred due to the technical limitations of the scanner.
4. The use of delayed scans limited to specific cases at the request of the radiologist.

APPENDIX B: 64 DETECTOR PEDIATRIC (MWD) IV CONTRAST INJECTION PROTOCOLS

CHILD WEIGHT (kg)	VENOUS PHASE RATE/VOLUME	ARTERIAL PHASE RATE/VOLUME	TOTAL CONTRAST DELIVERED
5	0.2sec/7mls	0.4sec/3mls	10
10	0.3sec/14mls	0.6sec/6mls	20
15	0.4sec/20mls	0.8sec/10mls	30
20	0.5sec/26mls	1.0sec/14mls	40

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) for Hemorrhagic Shock (CPG ID:38)

Reviews the range of accepted management approaches to profound shock and post-traumatic cardiac arrest and establishes indications for considering REBOA as a hemorrhage control adjunct.

PURPOSE

This CPG reviews the range of accepted management approaches for Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) as a hemorrhage control adjunct in traumatic shock and post-traumatic cardiac arrest in combat casualties. Updated guidelines exist for the use of REBOA in the civilian clinical setting. The use of REBOA in the military setting is less well defined. Prior CPGs relied heavily on expert opinion and consensus from military thought leaders. Civilian guidelines currently apply to well-resourced civilian centers with expertise in trauma care. Recommendations for use in the military setting must consider the unique challenges of the deployed environment. Mission parameters, tactical situation, casualty's physical location and evacuation capability also determine the capabilities available for combat casualty care. Mechanisms and patterns of injury, and the availability and experience level of surgical resources and resuscitation teams all influence the care rendered on the field. The optimal management is best determined by the clinician at the bedside. This document does not address the use of REBOA for indications other than trauma and traumatic hemorrhage.

BACKGROUND

- Hemorrhage continues to be a leading cause of preventable death on the battlefield. It can be broadly categorized as compressible or non-compressible depending on its location. Non-Compressible Torso Hemorrhage (NCTH) arises from trauma to the torso vessels, pulmonary parenchyma, solid abdominal organs, or the bony pelvis.[1] Because NCTH is not amenable to control by direct pressure or extremity tourniquet application, it is particularly lethal.[2]
- Resuscitative Aortic Occlusion (RAO) affords distal hemorrhage control while increasing cardiac afterload and thereby maintaining coronary and cerebral perfusion pressure until direct hemostasis can be achieved.[3] RAO has traditionally required a left thoracotomy or laparotomy for aortic exposure.[4-7] Resuscitative thoracotomy has a high mortality rate, due largely to the nature of the injuries leading to arrest.[8-10] Nonetheless, data from combat theaters indicate that there is a reasonable probability of long-term survival and recovery following RAO in appropriately selected casualties as described in the JTS Emergent Resuscitative Thoracotomy (ERT) CPG.[11-13]
- There is no high grade evidence defining the specific indications for REBOA, nor that REBOA improves survival or outcomes as compared to ERT.[14] There is literature demonstrating both a survival benefit with REBOA [15-16] as well as data suggesting that REBOA may actually worsen mortality.[17-18] The advent of the wireless ER-REBOA and a better understanding of REBOA indications has led to recent studies demonstrating the non-inferiority of REBOA. In patients that do not require CPR, REBOA has now shown a survival benefit.[19-23] In the highest quality prospective analysis available, REBOA improved survival beyond the emergency department and to hospital discharge compared to ERT when applied prior to traumatic cardiac arrest in patients with hemorrhagic shock.[23]
- REBOA is an alternative form of RAO for patients at risk of imminent cardiovascular collapse. It is performed through a femoral artery approach without the need for thoracotomy. REBOA is best applied prior to cardiovascular collapse when the site of hemorrhage is below the diaphragm and no open thoracic intervention is otherwise indicated.[23]
- ERT allows management of thoracic injuries and manual cardiac compression and thus remains the procedure of choice for patients with significant thoracic or cardiac injury. REBOA has been used in

combination with open thoracotomy and/or sternotomy as a resuscitative bridge to open surgical control of hemorrhage to treat thoracic great vessel injury.[24]

CURRENT RECOMMENDATIONS

- For the purpose of this CPG, REBOA remains contraindicated in the setting of major thoracic hemorrhage or pericardial tamponade.
- ERT may improve cardiac index as well as coronary and cerebral perfusion pressure compared to closed chest compression.[26] However, when closed chest compressions are combined with REBOA, cardiopulmonary resuscitation is more effective allowing for higher EtCO2 and cardiac compression fraction compared to open cardiac massage and aortic cross clamping.
- RAO poses a significant risk of life-threatening and limb-threatening complications. RAO is a time-critical intervention that should never be undertaken without expedient access to definitive hemorrhage control.[1–19,7-28,14,17,20]
- The major rate limiting step with REBOA is accurate and expedient common femoral artery (CFA) access. Ultrasound guided access is the preferred method for CFA access however, up to 50% of cases require open exposure. Smaller access sheaths are associated with improved outcomes.[29-32]
- Initial animal experiments demonstrated the potential merits of REBOA with occlusion times of up to 90 minutes.[33-34] However, long occlusion times resulted in nonsurvivable metabolic derangements and organ damage. These side effects were significantly lessened with occlusion times less than 30 minutes.[35]
- Outcomes for Zone 1 REBOA are optimized if occlusion times are between 15-30 minutes (See Appendix C for an illustration of the Zones of the Aorta). Occlusion times over 30 minutes are associated with higher ischemic complications and higher mortality.[17]
- Outcomes for Zone 3 REBOA are optimized if occlusion times are 30-60 minutes, though survival following longer occlusion times has been reported.[36]
- The American Association for the Surgery of Trauma (AAST) prospective Aortic Occlusion for Resuscitation in Trauma and Acute Care Surgery (AORTA) database contains cases with occlusion times exceeding the above recommendations, but this registry does not track the use of occlusion techniques such as intermittent and/or partial REBOA.[41] Partial and intermittent balloon techniques may reduce distal ischemia and extend tolerable occlusion times.[37-40] There is currently insufficient data to guide any consensus on this practice.[42,36]
- With increasing REBOA availability and provider experience, REBOA has successfully been utilized in multiple austere military locations.[43-47] In austere resuscitations, REBOA has been shown to improve the ability to triage multiple casualties, allow for blood product conservation, and assist in creating a 'bloodless' environment for damage control surgery.[45,47-48]
- Properly trained nurses are responsible for assisting in equipment availability and setup, accurate documentation and recording of catheter insertion distance in addition to safe and accurate patient handoff during transfer/transport.
- The implementation of this technique must be determined at each site based on training, experience, local resources, and evacuation timelines.

- Documentation of Aortic Occlusion via open thoracotomy or REBOA will be done using the Aortic Occlusion (AO) Procedure Note that is found in Appendix H of this CPG

REBOA IN TRAUMATIC ARREST & PROFOUND SHOCK

Indications for the use of REBOA are summarized below. These indications mirror the indications for resuscitative thoracotomy with the exception that shock or arrest secondary to penetrating chest trauma is a relative contraindication to REBOA (See the JTS Emergency Resuscitative Thoracotomy, 18 Jul 2018 CPG [13] As stated above, there is no high grade evidence defining the specific indications for REBOA. Data is, at best, mixed when comparing survival and outcomes of REBOA versus ERT.[14,23] However, there is at least one major trial that demonstrates that REBOA improves survival beyond the emergency department as well as to hospital discharge when compared to ERT for patients who are in hemorrhagic shock, but are pre-cardiac arrest.[23] For this reason, early recognition of hemorrhagic shock is vital when identifying patients who may benefit from REBOA.

INITIAL MANAGEMENT

Initial management priorities for patients with traumatic arrest or impending arrest include early control of hemorrhage and hemostatic resuscitation as described in the JTS Damage Control Resuscitation CPG. [50] The initial focus in patients presenting in profound hemorrhagic shock, to include loss of pulses, is to determine the best resuscitative strategy, and whether resuscitation is appropriate or futile in a moribund patient. The following must be rapidly determined:

- Mechanism and pattern of injury
- Presence of a pulse
- Duration of cardiac arrest
- Presence or absence of an organized, narrow complex cardiac rhythm and/or organized cardiac activity by ultrasound.
- Resources available
- Number of concurrent casualties

Patients exsanguinating from abdominal, pelvic, or junctional lower extremity bleeding may be candidates for REBOA. Such patients are identified by penetrating mechanism of injury to abdomen or pelvis, blast or blunt mechanism with positive FAST or suspected pelvic fracture, or massive proximal lower extremity trauma with signs of impending cardiovascular collapse.

Exsanguinating hemorrhage in the chest must be ruled out prior to placing REBOA—this can be done with chest tube placement, thoracostomy, x-ray, or thoracic ultrasound. In cases of major chest hemorrhage, occlusion of the aorta may increase thoracic bleeding and is thus best addressed via thoracotomy or sternotomy.

A decision algorithm for Resuscitative Aortic Occlusion (RAO) is found in Appendix A. If RAO is performed, concurrent hemostatic resuscitation and closed chest cardiac massage should continue while the procedure is performed.[51] If RAO is not performed, resuscitative efforts should cease unless there is a compelling reason to consider a non-traumatic arrest.

RESUSCITATIVE THORACOTOMY

The gold standard for aortic occlusion in traumatic arrest remains a left anterolateral thoracotomy (See JTS Emergent Resuscitative Thoracotomy CPG.)

TRANS-ABDOMINAL AORTIC OCCLUSION

The aorta can also be occluded trans-abdominally at any point along its length. It can be occluded with either application of a clamp or compression with a retractor or manually. Alternatively, balloon occlusion can be considered (below) as this can decrease instruments in the upper abdomen, depending on where the focus of bleeding is located. In obese patients with a large volume of hemoperitoneum or other intra-abdominal pathology, a trans-thoracic approach or a balloon approach to the aorta may be preferable. As with all other forms of RAO, restoration of aortic perfusion should be carefully coordinated with the rest of the team to minimize the effects of reperfusion and blood volume shifts.

REBOA STEPS

REBOA can be considered in 6 sequential steps:

1. Arterial access and positioning of sheath
2. Positioning of the balloon
3. Inflation of the balloon
4. Operative/procedural control of bleeding
5. Deflation of the balloon
6. Sheath removal

REBOA can be performed preemptively in patients with high-risk injury patterns and unstable physiologic parameters as described above. In this way, REBOA can be proactive rather than reactive in appropriate patients. The indications for REBOA are summarized in Appendix A for traumatic arrest and Appendix B in cases of profound shock. A schematic of the aortic anatomy is presented in Appendix C.[52] If proximal aortic occlusion is required, this is termed Zone 1, whereas distal aortic occlusion is termed Zone 3. Zone 1 REBOA deployment will be used in most patients presenting with hemorrhagic shock, and may be used in all patients with traumatic arrest, regardless of injury pattern, due to the benefits on a patient's mean arterial pressure (MAP).[53]

In clinical situations where REBOA is being considered, pre-emptive placement of an arterial line in the common femoral artery (CFA) is recommended. CFA access has consistently been identified as the rate limiting step to REBOA deployment.[30] Obtaining early CFA access in the form of an arterial line can greatly decrease REBOA placement time as a preplaced common femoral arterial line can quickly be re-wired to a REBOA introducer in the event of patient deterioration.

Preclinical research has shown a Zone 1 aortic occlusion time of 60 minutes or more results in significant metabolic derangement and organ damage that may offset any gain obtained by early hemorrhage control. 30 minute occlusion times had significantly improved outcomes without evidence of severe physiologic costs. Based on this data, Zone I REBOA should be deployed for no greater than 30 minutes. Zone III REBOA historically has been considered acceptable for up to 4-6 hours.[54-55] However, recent analysis in preclinical models have led to the revised recommendation to target Zone III balloon occlusion times of less than 30, and no greater than 60 minutes.[54-56,36]

After placing a REBOA, careful management of the femoral sheath is imperative. The majority of complications associated with REBOA use are related to the sheath and access site complications. Reported femoral access complications include arterial disruption, dissection, pseudoaneurysms, hematoma, thromboembolic phenomenon, and extremity ischemia. These complications have resulted in limb loss.[27,28] Due to the risk of sheath dislodgement or vessel wall damage excessive patient movement should be avoided. Patients with indwelling sheaths should be positioned supine or reverse Trendelenburg only. If the patient must be moved or turned, they should be kept in a flat position and log-rolled.

The provider, or assistant, should promptly document placement time, pre-/post-placement blood pressure and MAP, and REBOA insertion distance. Please use the Aortic Occlusion (AO) Procedure Note that is found in Appendix H of this CPG for specific REBOA documentation. It is also available on the JTS Website at https://jts.health.mil/index.cfm/documents/forms_after_action - under CPG Forms. Balloon volume and inflation time should be noted at the insertion site for reference by all providers caring for the patient. The provider is responsible for prevention of catheter migration, particularly during patient transport. A provider who is knowledgeable about the management of REBOA should attend to the patient while awaiting definitive surgical repair, to include during transport. The trained provider is responsible for ensuring a safe and competent hand off.

While the sheath is in place, hourly neurovascular assessments of the bilateral lower extremities should be completed. These assessments should continue for 24 hours after removal of the sheath to allow for early identification and intervention of access site complications. In addition, follow-on duplex imaging (24-48 hours post REBOA) of the access site allows for early identification and treatment of any access site complications. This may be performed either at the Role 3 facility or as soon as possible after arrival at a Role 4 facility, depending on resources available to perform and interpret the ultrasound.

Once definitive hemorrhage control has been obtained, the REBOA sheath should be removed and 30 minutes of direct pressure applied to the CFA access site. If arterial pressure monitoring is still required an alternate line site should be considered. An angiogram through the sheath to document distal limb perfusion is best practice, though not always available. If a large sheath size is used, a patient is coagulopathic, or there is technical difficulty in sheath removal a cut down and arterial repair, patch or graft may be required. This may be best accomplished in the Role 3 environment with access to specialists and/or surgical backup.[21]

The balloon should be deflated once specific vascular control or definitive hemorrhage control has been obtained. Communication with the assistant holding the apparatus securing the catheter and the anesthesia team is critical before consideration of deflating the balloon. When deflating the balloon turn the three-way stopcock and withdraw saline slowly and deflate the balloon slowly as this step can be anticipated to result in a significant decrease in afterload and hypotension and may result in cardiac collapse. Additional resuscitation may be needed while the balloon is slowly deflated. After balloon deflation, the team should anticipate hemodynamic changes related to reperfusion, washout of metabolic byproducts, and acidosis. As such, intermittent balloon inflation and deflation may be necessary during ongoing resuscitation until hemodynamic stability is restored.

Even in an austere environment, protocols for use and follow on care should be planned and discussed prior to implementation. Team training and awareness of pitfalls are critical to ensure the best possible outcomes.

If definitive hemorrhage is not obtained, leaving the sheath in place without aortic occlusion may be a valid option. By leaving the sheath in place, the REBOA can easily be reinserted and aortic occlusion can quickly be obtained if rebleeding occurs or hemorrhage continues.[38] In general, and situation/resource dependent, the sheath should be left in during any active or ongoing resuscitation. The sheath should not be removed immediately prior to transport, and is best removed where vascular complications can be treated and managed.

A sheath MUST NEVER be left in for transfer to a host nation facility.

AEROMEDICAL EVACUATION CONSIDERATIONS

Patients who receive REBOA at a Role 2 and need to be evacuated to a higher level of care should have hemorrhage control addressed and balloon deflated prior to transfer. Under no circumstance should a Zone 1 REBOA remain inflated during transport. In rare situations when a short-distance rotary-wing evacuation to higher level of care is possible, a Zone 3 REBOA inserted at Role 2 may remain inflated during transport however this requires exceptional communication and planning to avoid undue risk of ischemic injury.

If rotary-wing transport is available, a medical provider trained in hemodynamic monitoring and manipulation of the occlusion balloon should accompany the casualty at all times. If a REBOA sheath is in place in a trauma patient, re-placement/re-inflation of the balloon during transport is an option for trained providers in the event of sudden profound hypotension. Simultaneous blood transfusion is needed and balloon inflation time should not exceed 15 min in Zone I.

The essential equipment for REBOA is provided in Appendix D while the appropriate technical steps and considerations are summarized in Appendix E.

TRAINING

Prior to using REBOA, providers should have a thorough knowledge of the device, its indications, use and potential complications. Organized, curriculum-based REBOA training courses such as the American College of Surgeon's Basic Endovascular Skills for Trauma (BEST) course or the 'Resuscitation Adjuncts: Prehospital Transfusion & REBOA' (RAPToR) Course are available. Successful completion of a REBOA training course, including a didactic and hands on skills component, is recommended prior utilization of the device. Skills training can be achieved through high-fidelity simulation, perfused cadaver or live tissue training. Critical skills include access to the CFA with ultrasound and cut down, sheath placement and positioning, and REBOA operation and removal. Anatomically correct models are critical for accurate training of CFA access skills, and thus perfused cadavers are recommended to meet this requirement.[57-59]

Ultimately, the decision to perform REBOA on patients at high risk for hemorrhagic death will depend on the specific injury pattern, individual provider experience, team training, and local resources.

REBOA USE BY NON-SURGICAL RESUSCITATION TEAMS

Advanced resuscitation teams may be utilized in austere environments as a bridge to surgical hemorrhage control. Data on the effectiveness of this approach are lacking. REBOA in this setting may be considered in the rare circumstance that all of the following conditions are met:

1. The casualty would otherwise die in 15-30 minutes without REBOA (NCTH, refractory hemorrhagic shock)

2. A physician experienced in REBOA therapy is present

3. Blood product resuscitation, preferably whole blood, is available but failing to resuscitate the patient

4. Time to definitive hemorrhage control is short (ideally <15 min Zone 1, <30 min Zone 3).

The narrow therapeutic window of aortic occlusion is the major limitation of REBOA. Techniques for lengthening aortic occlusion time are being investigated such as partial REBOA (pREBOA), intermittent REBOA (iREBOA), regional hypothermia, and pharmacologic interventions to decrease ischemia or enhance ischemia resistance. Multiple descriptions of pREBOA and iREBOA techniques in animal models have been described. One protocol recommended by the Committee on Tactical Combat Casualty Care (CoTCCC) describes iREBOA as an initial 15min of occlusion time, followed by balloon deflation and reassessment of the patient's systolic blood pressure (SBP). If SBP > 80mmHg, the balloon should remain deflated. If SBP drops to $\leq$ 80mmHg the balloon should be re-inflated. If the SBP dropped below 80mmHg in less than 3 minutes, balloon occlusion will be maintained for up to 30 min as resuscitation continues. If decompensation occurs after 3 minutes, the balloon should re-inflated and deflated again after 10 minutes for reassessment. This cycle continues for a total occlusion time up to 120 min or until the patient's blood pressure remains stable above 80mmHg. iREBOA has come under criticism due to multiple limitations of the initial study and lack of other supportive studies.[37-38,42,60]

REBOA PITFALLS

- Making the decision to perform REBOA too late. Mortality is high after loss of pulses has occurred, as it is with ERT.
- Difficulty locating the common femoral artery in the groin. The clinician must be very familiar with open, percutaneous, and ultrasound guided femoral access techniques. Early CFA access is recommended even if REBOA not utilized.
- Insertion of the REBOA too low, below the femoral artery bifurcation. The catheter should be placed in the common femoral artery, just below the inguinal ligament. Insertion into the superficial femoral artery is associated with an increased risk of thrombosis and limb loss.
- Unrecognized proximal femoral or iliac artery transection preventing endovascular access on the side of the injury. This may occur with penetrating pelvic trauma or severe pelvic fracture—check bilateral femoral pulses and access the side with a stronger pulse if there is a difference. Do not hesitate to switch to the opposite groin or convert to thoracotomy.

- Failure to address chest pathology. Always evaluate the chest by X-ray, ultrasound, or bilateral chest tube placement to identify and treat significant hemothorax or pneumothorax. Convert to thoracotomy to address massive hemothorax.
- Catheter or guidewire does not pass freely. This could indicate injury to the vessel. Do not inflate balloon. Consider accessing the opposite groin or convert to thoracotomy.
- Over-inflating the balloon. The ER REBOA balloon capacity is 24 ml. Zone 1 may require as little as 8 ml and Zone 3 as little as 2 ml to achieve occlusion. Over-inflation may rupture the balloon or injure the aorta.
- Leaving the balloon inflated too long. Only 30 minutes of Zone 1 occlusion is advised, and the shorter the better. Achieve rapid control of bleeding sites with temporizing measures such as clamping to allow the earliest reperfusion; most suturing, ligating, solid organ removal, and vascular shunting may be done after balloon deflation. Death secondary to ischemic injury has been reported with longer occlusion times.
- Failure to work with a heightened level of urgency once REBOA is placed. Some patients may regain "stability," however balloon occlusion is just like a cross clamp, with the same complications of visceral and spinal ischemia. Every effort should be made to restore perfusion as soon as possible to limit ischemia.
- Failure to adequately secure the REBOA catheter after balloon inflation, resulting in migration of the balloon. The catheter position must be maintained during and after inflation to avoid distal migration until aortic pressure and pulsatility are restored.
- Deflating the balloon too quickly before adequate volume resuscitation. Ensure that the anesthesia team is prepared for reperfusion prior to balloon deflation.
- Premature removal of the arterial sheath. The sheath should remain in place if the patient is coagulopathic, may have ongoing bleeding in the abdomen or pelvis, or is being transported within theater to a higher level of care.
- Injury to the arterial access point. After removal of the sheath, monitor the instrumented leg closely for re-bleeding and thrombus/intimal injury. Decreased lower extremity perfusion may require further angiography, thrombectomy, or direct arterial repair.
- Committing multiple resources to a futile resuscitation. Anticipate massive transfusion, personnel required, surgical supplies, diversion of resources from more salvageable casualties, etc.

FUTURE CONSIDERATIONS

A retrospective capability gap analysis of the UK Joint Theatre Trauma Registry suggested that as many as one in five severely injured casualties have wounds that may be amenable to treatment with REBOA.[61] The development of the 7 Fr ER REBOA catheter facilitates insertion of the device and may lead to more widespread use of this approach in the austere environment. Training non-physician caregivers to place REBOAs in the prehospital settings is being investigated.[62-63] Partial REBOA, intermittent REBOA, regional hypothermia, and pharmacologic adjuncts continue to undergo validation as a means of prolonging aortic occlusion time.[60,39,64] Ongoing research seeks to identify modifications to the REBOA technique that may be required when it is combined with other resuscitation modalities such as tranexamic acid. Researchers are also striving to clarify patient selection, evaluating the impact of REBOA on thoracic injury, and traumatic brain injury.[65] All of these advances should refine the

optimal use of this resuscitation adjunct. Longitudinal data in the civilian and military setting will assist in defining the ideal clinical situation in which REBOA can be of maximal benefit.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- Patients with AIS chest, abdomen, pelvis, and/or lower limb ≥3 with SBP >0 and <90 or CPR in progress on arrival to first MTF AND not isolated head injury (AIS head/face/neck = 5 or 6).
- Patients who received REBOA.

INTENT (EXPECTED OUTCOMES)

1. REBOA is not performed in patients with no signs of life or CPR >15 minutes or isolated severe TBI, penetrating neck injury, or penetrating extremity injury.
2. If performed, REBOA was performed for the indication of hemorrhagic shock associated with abdominal, pelvic, or junctional lower extremity bleeding, or other indication is clearly documented.
3. If REBOA performed, the patient was assessed for thoracic hemorrhage (EFAST or CXR results documented or bilateral chest tubes placed).
4. Blood pressure pre and post REBOA and balloon times (inflation and deflation) are documented in REBOA procedure note.
5. Lower extremity pulses are documented after balloon deflation.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients who had REBOA performed for hemorrhagic shock associated with abdominal, pelvic, or junctional lower extremity bleeding.
2. Number and percentage of patients who had REBOA performed who were assessed for thoracic hemorrhage (EFAST or CXR results documented or bilateral chest tubes placed).
3. Number and percentage of patients who had REBOA performed with complete REBOA procedure note to include documented blood pressure pre and post REBOA and documented balloon times (inflation and deflation).
4. Number and percentage of patients who had REBOA performed with lower extremity pulses documented after balloon deflation.
5. Number and percentage of patients who had REBOA performed with surgical hemorrhage control procedure or documentation that procedure not needed.
6. Number and percentage of patients who underwent ERT or REBOA in the population of interest.
7. Number and percentage of patients who did not undergo ERT or REBOA in the population of interest.

8. Number and percentage of patients who underwent ERT or REBOA who survived 24 hrs, 7 days, 30 days (assume alive if discharged alive prior to each time point).

9. Number and percentage of patients who did not undergo ERT or REBOA in the population of interest who were declared KIA/DOA or who survived 24 hrs, 7 days, 30 days (assume alive if discharged alive prior to each time point).

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

PI DATA CAPTURE AND REPORTING

- Number of REBOA interventions, performance, and adherence measures will be reported quarterly by JTS PI Branch Chief to the JTS Chief.
- JTS will identify REBOA patients in the trauma registry and facilitate capture of complete medical records.

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief, and the JTS PI Branch.

RESPONSIBILITIES

It is the responsibility of the JTS PI Branch Chief to ensure system-level compliance with this CPG. It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

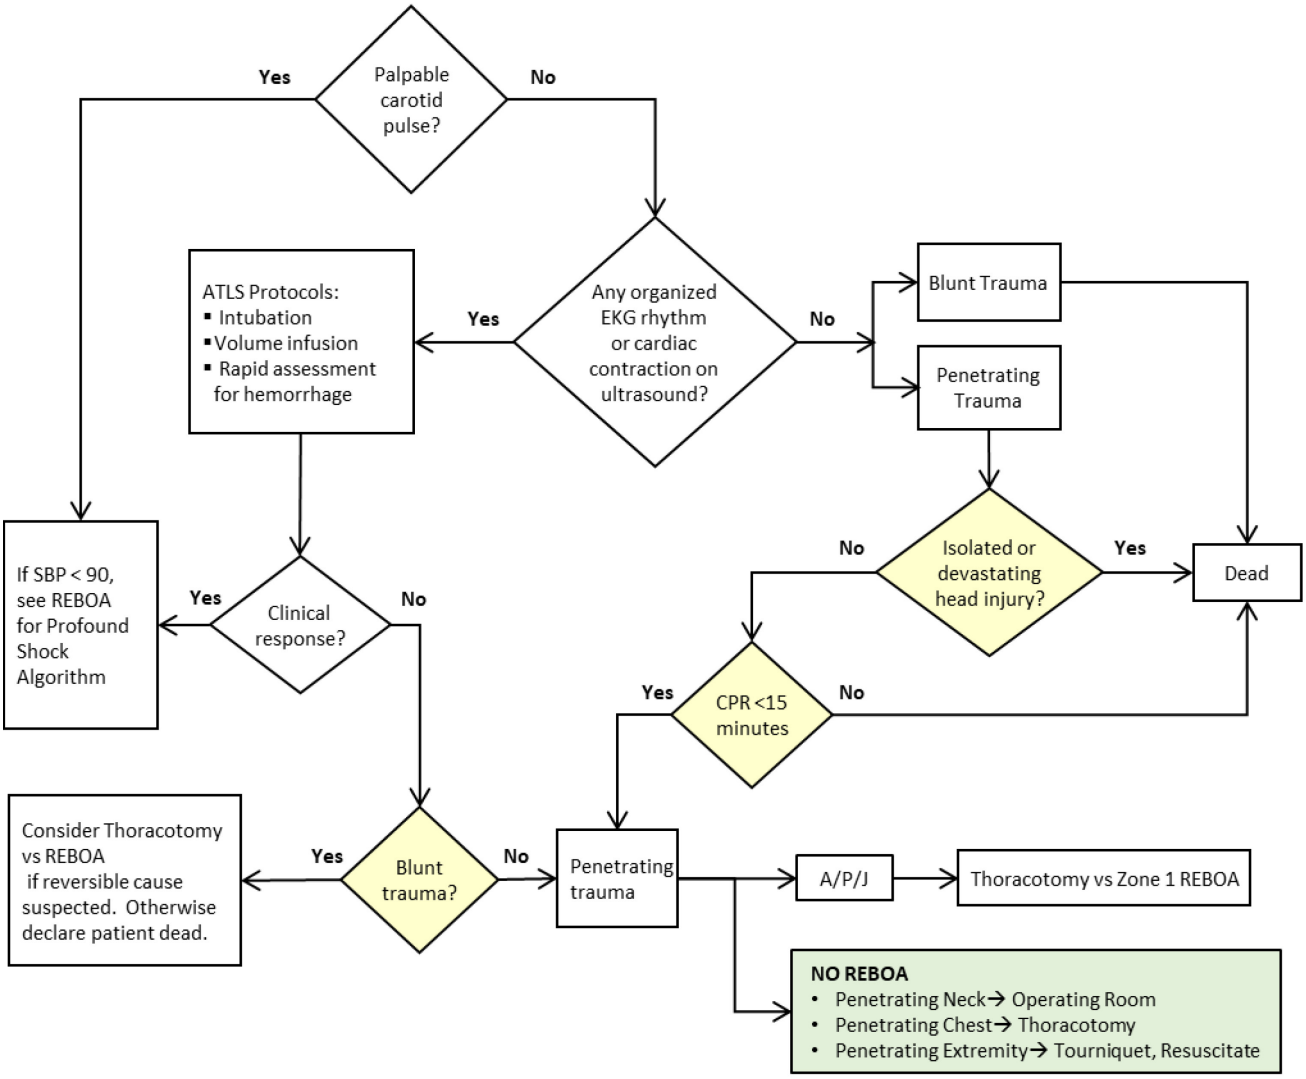
APPENDIX A: TRAUMATIC ARREST ALGORITHM

Traumatic Arrest Algorithm for Resuscitative Aortic Exclusion

- Blunt trauma with no major chest bleeding seen on CXR, ultrasound, or bilateral chest tubes
- Penetrating trauma to abdomen/pelvis



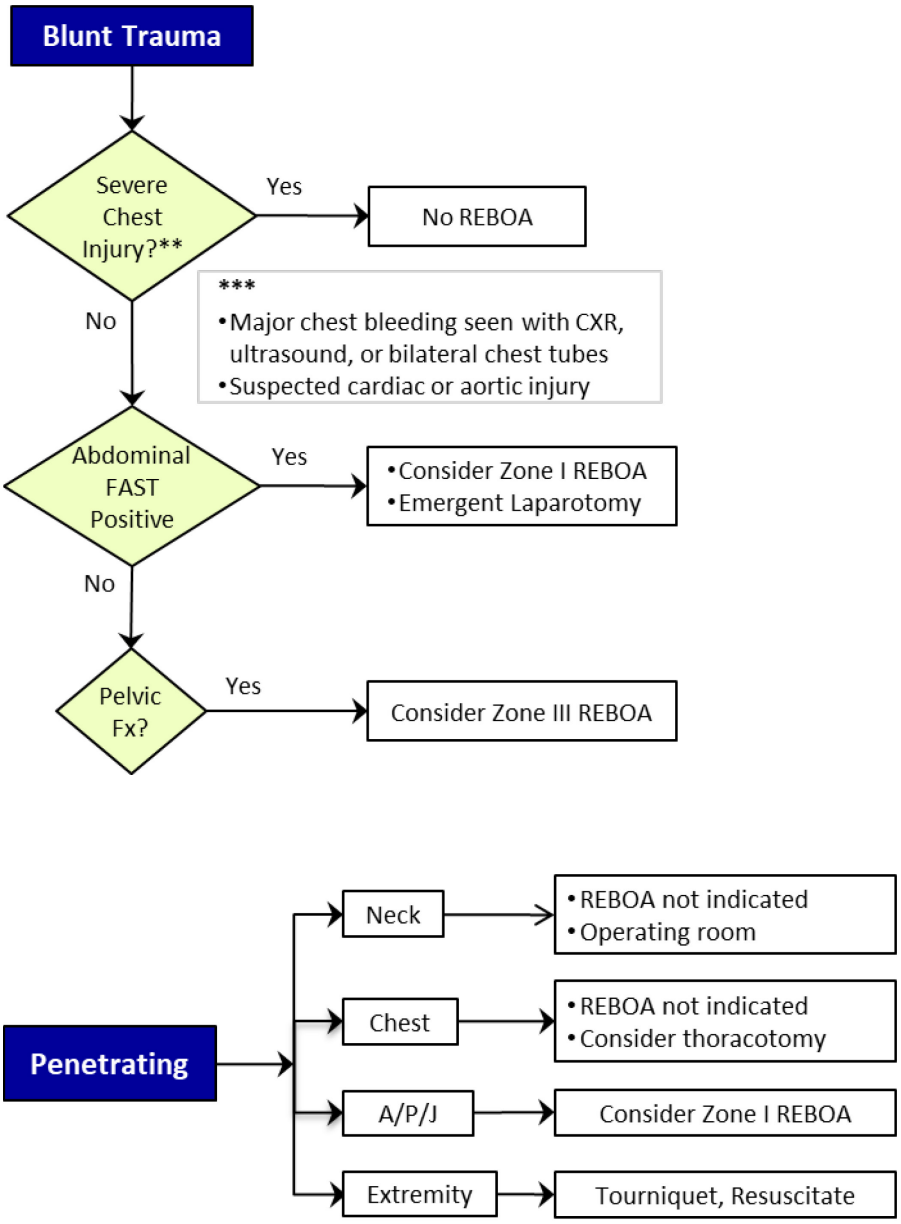
REBOA: Resuscitative Endovascular Balloon Occlusion of the Aorta; CXR: Chest X-Ray; EFAST: Extended Focused Assessment with Sonography for Trauma; ATLS: Advanced Trauma Life Support; EKG: Electrocardiogram; SBP: Systolic Blood Pressure; CPR: Cardiopulmonary Resuscitation; A/P/J: Abdomen/Pelvis/ Junctional Lower Extremity.

Zone I REBOA: placement of aortic balloon in the thoracic aorta (insert catheter to 46 cm, or measure the balloon to mid sternum, or /P-tip to the sternal notch)

Zone III REBOA: placement of aortic balloon directly above the aortic bifurcation (insert catheter to 27 cm or measure the balloon to the umbilicus or P-tip to the xyphoid process).

APPENDIX B: ALGORITHM FOR USE OF REBOA FOR PROFOUND SHOCK

SBP<90 with Transient or No Response to initial ATLS Resuscitation

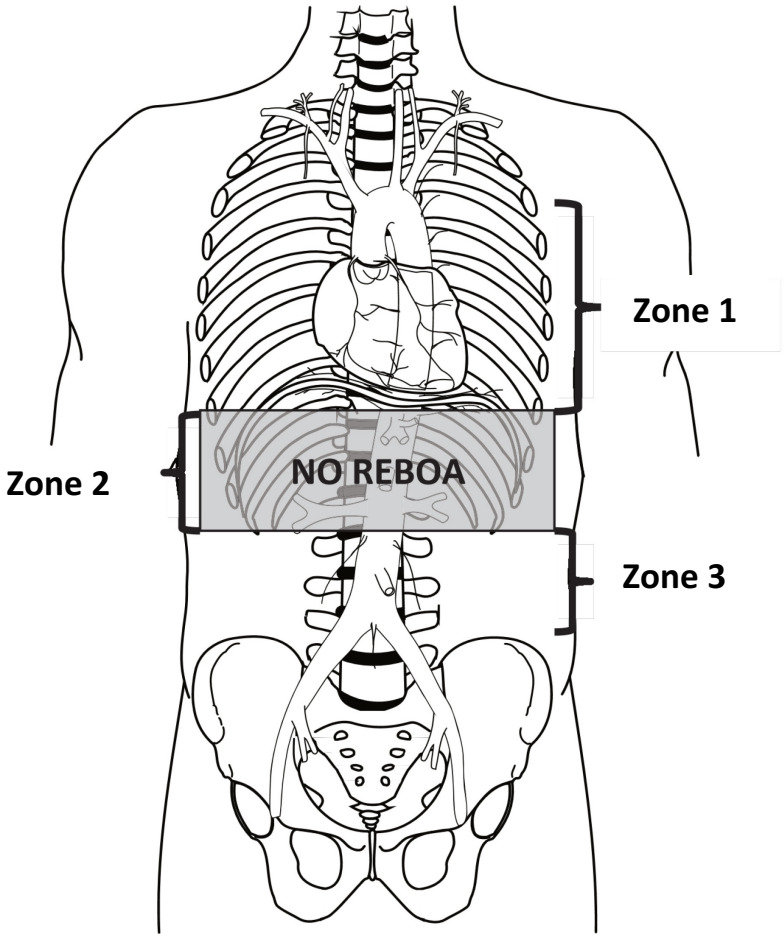


REBOA: Resuscitative Endovascular Balloon Occlusion of the Aorta; CXR: Chest X-Ray; EFAST: Extended Focused Assessment with Sonography for Trauma; ATLS: Advanced Trauma Life Support; EKG: Electrocardiogram; SBP: Systolic Blood Pressure; CPR: Cardiopulmonary Resuscitation; A/P/J: Abdomen/Pelvis/ Junctional Lower Extremity.

Zone I REBOA: placement of aortic balloon in the thoracic aorta (insert catheter to 46 cm, or measure the balloon to mid sternum, or /P-tip to the sternal notch)

Zone III REBOA: placement of aortic balloon directly above the aortic bifurcation (insert catheter to 27 cm or measure the balloon to the umbilicus or P-tip to the xyphoid process).

APPENDIX C: AORTIC ZONES



APPENDIX D: EQUIPMENT AND SUPPLIES FOR REBOA

- Ultrasound (linear probe for vascular access)
- Surgical set for open femoral artery exposure, including self-retaining retractors
- Scalpel (#11 or #15)
- 5 Fr micropuncture set or 18 Ga arterial line set (e.g., Cook Medical G43870, NSN 6515016591707; or Vascular Solutions, Inc 7208V; or Arrow Femoral Arterial Line UM-04018)
- 7 Fr arterial sheath (e.g., ER REBOA Catheter Introducer kit, Prytime Medical KT1835C; or Cordis Avanti 402-607x, NSN 6515016594864)
- ER REBOA catheter (Prytime Medical, NSN 6515016580745)
- Central line securing device
- Suture and Silk ties
- 3-way stopcock
- 30 ml Luer lock syringe
- 10 ml pre filled saline syringe x3
- Injectable saline (100 mL)
- Optional: Intravenous contrast (mix 8 mL in 16 mL injectable saline for balloon)
- Standard A-line setup; or Compass Device
- If able to be sterile: Ultrasound probe cover, Full body drapes, Sterile Scrub

APPENDIX E: REBOA STEPS USING 7 FRENCH ER-REBOA

The procedure may reviewed online using the following links:

Part 1: https://www.youtube.com/watch?v=-U7MkU3eA7E

Part 2: https://www.youtube.com/watch?v=DZ5LCEt7PBk

STEP 1: Arterial Access and Positioning of the Sheath

Establishing Arterial Access:

Access to the arterial circulation for REBOA for trauma should be obtained through the common femoral artery using one of three techniques: percutaneous, open exposure (e.g., cut down), or exchange over a guide wire from an existing common femoral arterial line.

Ultrasound is used to identify the common femoral artery above the branch of the profunda and the needle visualized passing into the common femoral artery (linear array transducer preferred). Ultrasound guided access improves first pass access and decreases complications.[1] Once identified, the artery should be entered at a 45-degree angle with the needle, using either a 5 Fr micropuncture kit or 18 gauge femoral arterial line kit. After the wire has been passed into the artery, the needle is removed and a small incision made at the interface of the wire and skin and the catheter is passed over the wire.

Using landmarks, the location of the inguinal ligament is identified between the Anterior Superior Iliac Spine (ASIS) and pubic symphysis (NOT the inguinal crease). The common femoral artery is then accessed 2 cm below the inguinal ligament.

Selection and Positioning of Initial Sheath:

If REBOA is indicated, the arterial access catheter must be upsized to a 7 Fr sheath. This maneuver is accomplished by placing a 0.035 guide wire greater than twice the length of the existing arterial catheter through its inner lumen allowing the catheter to be removed over the wire while maintaining arterial access. After a larger opening is created at the wire/skin interface, the 7 Fr working sheath with its internal dilator in position can be inserted over the wire. When urgently needed, a 7 Fr sheath may be placed as the initial step by placing the 7F sheath over the 0.035 guide wire though this can increase risk of access site damage.

The sheath's internal dilator must be firmly held in place to allow a smooth reverse taper from the wire to the diameter of the sheath to avoid arterial intimal injury. Once the dilator and sheath have been advanced over the wire through the skin into the artery, the dilator and wire are removed, leaving the sheath in place. It is important that the operator assure that the stopcock is in the "off" position to reduce bleeding.

STEP 2: Selection and Positioning of the Balloon

Selection of a Balloon:

The ER REBOA (Prytime Medical, New Braunfels, TX) is the only REBOA device covered by this CPG, as that it is the product chosen for use by the DoD. This is wire-free and fluoroscopy free and smaller caliber than previously used balloons, allowing fewer steps for insertion and a smaller introducer sheath (7 Fr). It also has arterial pressure monitoring capability.

Balloon Preparation:

Attach 30cc syringe to the ER-REBOA balloon port. The syringe will be filled with 24cc of 1/3 contrast 2/3 saline, or all saline if contrast not available. Negative pressure should be applied to the balloon to remove any air, then locked in place with the plunger at the 30cc mark on the syringe.

The a-line should be flushed with saline. The balloon will now pass easily into the peel-away sheath.

If using the pressure monitoring capabilities, the pressure sensor and tubing should be attached to the catheter's arterial stopcock and flushed with saline using standard arterial line setup and transducer connected to a monitor. Once the catheter is inserted, continuous care must be taken to prevent inadvertent emboli (air, thrombus, etc…) as well as keeping the a-line patent.

Balloon Positioning:

For Zone I occlusion, the catheter should be inserted 46 cm (or measured with the balloon from the midsternum, or the P-tip from the sternal notch to the femoral access catheter). For Zone III occlusion, the catheter should be inserted 28 cm (or the balloon measured at the umbilicus or the P-tip measured from the xiphoid process to the femoral access catheter). Distances are noted on the catheter shaft.

The peel away sheath is advanced over the P-tip and balloon to protect these as they enter the 7F sheath. The peel away sheath is advanced into the end of the 7F sheath approximately 5mm or until it hits a "stop." The REBOA catheter is then advanced 10cm into the sheath. The peel away sheath can then be slid back onto the catheter hub or removed, if full advancement is necessary. The catheter should be advanced to the predetermined depth. Plain film x-ray, ultrasound, or fluoroscopy can confirm correct positioning of the catheter and adjustments can be made if necessary, prior to inflation. There are two radio-opaque markers on the catheter to designate the location of the balloon. In cases of arrest there is no role for position confirmation and this can be done at a later time when the patient is stable.

STEP 3: Inflation of the Balloon, Securing of the Apparatus, and Monitoring

Inflation of the Balloon:

A 30 ml syringe should be used. Fill syringe to 24cc with 1/3 iodinated contrast and 2/3 saline, or all saline if contrast not available.[2] Balloon should be inflated until the blood pressure is augmented and contralateral femoral pulse is stopped, approximately 8 ml for Zone I or 2 ml for Zone III.

Do not over-inflate the balloon—balloon capacity is 24 ml—over-inflation can rupture the balloon or damage the aorta. Balloon inflation can be guided by fluoroscopy, hemodynamic response, and/or loss of the contralateral pulse. When fluoroscopy is available, inflate the balloon until the outer edges of the balloon change from convex to parallel as the balloon takes on the contour of the aortic wall. When inflation appears adequate to gain aortic wall apposition and/or central blood pressure is augmented, the three-way stopcock on the shaft of the balloon should be locked to maintain inflation and occlusion while other maneuvers are undertaken. Confirmatory X-ray may be used for radiographic confirmation of location. If no imaging is available in the austere environment, definitive confirmation of the balloon positioning should be accomplished directly with "hands-on" at the time of

laparotomy. If the balloon is found to be malpositioned (e.g., Zone 2) the balloon can be deflated and catheter positioned to Zone I or III and the balloon re-inflated.

Securing the Inflated Balloon and Sheath:

As the central aortic pressure improves, there is a risk of the catheter moving caudally. To prevent catheter migration, HOLD the catheter in place or secure the catheter to the sheath, and sheath to the patient with a central line attachment device. For added monitoring and security, assign an assistant the task of holding the apparatus until balloon deflation is desired.

Managing the patient pre-op:

A trained assistant should monitor and communicate the "big three" factors imperative to maintenance of successful REBOA: mean arterial pressure (MAP), maintenance of catheter position, and maintenance of occlusion (balloon inflation).

MAP: Immediately upon balloon inflation, and successful arterial occlusion, the MAP increases. In order to prevent negative effects of increased circulating volume leading to hypertension, the clinician should consider partial aortic occlusion if the MAP exceeds 100. The arterial waveform should be monitored for changes including over-dampening (flattened waveform) or under-dampening (hyper-dynamic waveform). Measures should be taken to ensure that the transducer, pressure tubing, and lines are problem-free. The pressure monitoring system should include dedicated pressure tubing, fully primed and air-free, not of excessive length, and with minimal use of stopcocks. Be sure all connections are tight, but not over-tightened.

Catheter position: The clinician should frequently check the measured distance of the catheter at the sheath to ensure that the catheter is not migrating. Notify the physician if catheter migration has occurred.

Maintenance of occlusion: Distal pulses should be monitored frequently. If pulses are present, and partial-REBOA is not intended, then balloon occlusion is not achieved and must be corrected. Notify the physician to add 0.5mm saline to the balloon and recheck MAP and distal pulses for evidence of complete occlusion.

STEP 4: Operative/Procedural Control of Bleeding

Control of bleeding below the diaphragm must occur very quickly, with a goal to keep the total aortic occlusion time less than 30 minutes. It is therefore important to start with damage control maneuvers to control bleeding such as clamping of the splenic or renal hilum, Pringle maneuver, clamping of any injured blood vessel, packing, or obtaining proximal and distal control of an injured blood vessel. At times, definitive control of bleeding such as solid organ removal, ligation of clamped vessels, or vascular shunt placement, may be deferred until after the REBOA has been deflated.

In patients with pelvic fractures, interventional radiology embolization may be considered when available, after intra-abdominal hemorrhage has been ruled out or controlled and the REBOA has been positioned in Zone 3.

STEP 5: Deflation of the Balloon

The balloon should be deflated once hemorrhage control has been obtained. Communicating with the assistant securing the catheter and the anesthesia team is critical before deflating the balloon. When deflating the balloon turn the three-way stopcock and withdraw saline slowly as this step can be anticipated to result in significant hypotension and may result in cardiac collapse. Further resuscitation may be necessary while deflating the balloon. While one person focuses on slowly deflating the balloon, another should hold the catheter and sheath in the position to avoid unintentional migration should the need to rapidly re-inflate the balloon arise. After balloon deflation, the team should anticipate hemodynamic changes related to reperfusion, washout of metabolic byproducts, and acidosis. As such, intermittent balloon inflation and deflation may be necessary during ongoing resuscitation until hemodynamic stability is restored.

STEP 6: Removal of the Balloon and Sheath

After REBOA is no longer required, the balloon may be deflated. It is imperative to have close communication with the anesthesia team to anticipate transient hypotension when the balloon is deflated. Once definitive hemorrhage control has been obtained, the REBOA sheath should be removed and 30 minutes of direct pressure applied to the CFA access site.

An angiogram through the sheath to document distal limb perfusion is best practice, though not always available. An aortogram may be best accomplished in the Role 3 environment with access to specialists and/or surgical backup.

The sheath should not be removed immediately prior to transport and is best removed where vascular complications can be treated and managed. If the anticipated patient transport time is less than 4 hours, the sheath may remain in place in patients with a high risk of rebleeding/continued bleeding. If patient transport time exceeds 4 hours the sheath should be removed at least 30 minutes prior to transport to allow for sufficient hemostasis at the CFA puncture site. These patients should be monitored closely en route for signs of access site complications. While the sheath is in place and up to 24hrs after removal, the patient should undergo bilateral lower extremity neurovascular checks every 1 hour. Providers should have a low threshold to involve vascular surgery or obtain a lower extremity arteriogram is any abnormalities arise.

Again, the sheath must NEVER be left in place for transfer to a host nation hospital.

Open vascular repair may be needed if a large sheath size is used, the patient is coagulopathic, or there is technical difficulty in sheath removal. If open surgical repair of the arterial access site is necessary, the femoral artery proximal and distal to the sheath entry site should be exposed to allow control. Proximally, this may require dissection for 2 cm to 3 cm underneath the inguinal ligament as an assistant uses a narrow handheld retractor (e.g., short Wylie renal vein retractor) to lift the inguinal ligament off of the femoral sheath. Exposure distal to the sheath entry site often requires identification and control of both the superficial and profunda femoris arteries. Once proximal and distal exposure and control with vessel loops or vascular clamps have been accomplished, the sheath may be removed. Consideration should be made for passage of embolectomy catheters distally to remove any potential clot and assure back bleeding. The resulting arteriotomy, especially the intima, should be closely examined and tailored with Potts scissors if necessary to allow primary transverse closure. Closure of the arteriotomy should be performed transversely using 5-0 or 6-0 permanent monofilament suture in either an interrupted or running fashion with care to capture all layers of the arterial wall with passage of the needle. Before closing the last suture, forward bleeding and back bleeding of the arterial segments should be allowed followed by flushing of the surface with heparinized saline. Restoration of flow through the arterial segment should be confirmed using manual palpation for pulses distally and use of continuous wave Doppler of both the artery and more distal extremity. If there is any question of flow, it is recommended to perform an angiogram and appropriate intervention if any abnormalities are noted. Closure of the soft tissues above the femoral artery is accomplished in layers using absorbable suture in the soft tissues.

APPENDIX F: ER-REBOA PROCEDURE CHECKLIST

1. Resuscitate per advanced trauma life support.
2. Rule out major thoracic trauma (CXR/EFAST/Bilateral chest tubes)
3. Confirm abdominopelvic source of shock (FAST exam and Pelvic X-ray if blunt trauma)
4. Confirm bilateral femoral pulses are present
5. Establish arterial access with 7 Fr Sheath in an uninjured common femoral artery
6. Measure balloon distance
7. Evacuate the balloon
8. Flush the arterial line
9. Insert the catheter
10. Inflate the balloon (Zone 1: start with 8ml; Zone 3: start with 2ml)
11. Secure the catheter
12. Control major bleeding
13. Monitor the patient, hemodynamics, catheter, and sheath
14. Resuscitate and deflate the balloon
15. Complete damage control surgery
16. Remove sheath when coagulopathy corrected
17. Check distal pulses after sheath removal

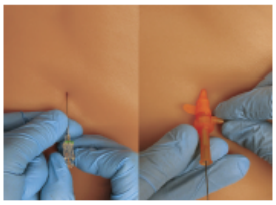
APPENDIX G: ER REBOA QUICK REFERENCE GUIDE

Disclaimer: The JTS does not endorse a specific catheter or products for REBOA. The purpose of this reference guide is to educate providers on the proper use of the catheter to improve clinical care.

The ER-REBOA™ Catheter Quick Reference Guide

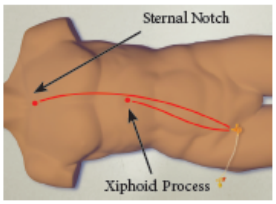
6 REBOA Steps: ME-FIIS (Pronounced 'Me-Fiz')

Get Early CFA Access



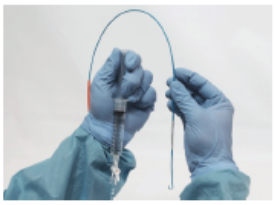
Obtain access using standard techniques

1. Measure

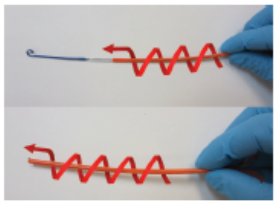


Placement depth[1,2,3,4,5,6]
- Zone 1: ~ 46 cm
- Zone 3 : ~ 28 cm

2. Empty



Deflate balloon
- Ensure balloon is fully deflated
- Hold vacuum for **5 seconds** and close stopcock

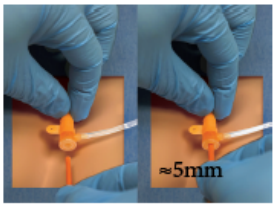


Advance & twist peel-away to cover P-tip®
- Corkscrew twist to wrap balloon tightly
- Ensure the balloon and P-tip® are captured

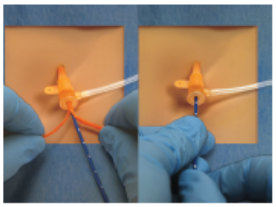
3. Flush

Attach & flush arterial line
- Use standard techniques
- Ensure all air is purged

4. Insert



Insert peel-away into valve
- Approximately 5 mm



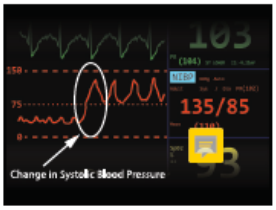
Advance catheter to desired depth
- Hold orange peel-away
- Advance blue Catheter
- Pull peel-away back after balloon passes valve

Position catheter
If available, use x-ray or fluoroscopy to confirm position using radiopaque markers

5. Inflate[1,2,3,4,5,6]

Inflation Volume	
Zone 1	Start with 8 cc
Zone 3	Start with 2 cc

"Start 2, Start 8, Don't Overinflate."
Start small, then check



Monitor arterial waveform feedback
- Look for increase in blood pressure above balloon
- Feel for loss of contralateral pulse
- **Mark time of inflation**

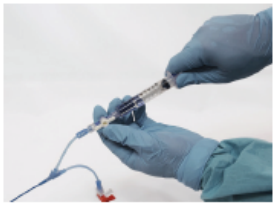
6. Secure

Secure Catheter close to the introducer sheath

Provide Definitive Treatment

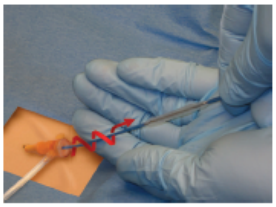
Provide definitive hemorrhage control
- The clock is ticking!
- Move quickly to definitive control

Deflate



Deflate slowly
- Prepare team for potential rebound hypotension

Remove



Fully deflate balloon
- Hold vacuum for **5 seconds** and close stopcock
- Corkscrew twist the catheter to facilitate removal
- If necessary, remove catheter and introducer sheath as a unit

Caution

Check for full and equal pulse in each leg using your standard technique

APPENDIX I: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Sepsis Management in Prolonged Field Care

This CPG focuses on the most common etiologies of sepsis, and the treatments of those forms of sepsis that the austere provider can reasonably manage.

INTRODUCTION

This Role 1 prolonged field care (PFC) guideline is intended for use in the austere environment when evacuation to higher level of care is not immediately possible. A provider must first be an expert in Tactical Combat Casualty Care (TCCC). The intent of this guideline is to provide a functional, evidence-based and experience-based solution to those individuals who must manage patients suspected of having or diagnosed with sepsis in an austere environment. Emphasis is placed on the basics of diagnosis and treatment using the tools most familiar to a Role 1 provider. Ideal hospital techniques are adapted to meet the limitations of austere environments while still maintaining the highest standards of care possible.

Sepsis and septic shock are medical emergencies. Patients suspected of having either of these conditions should be immediately evacuated out of the austere environment to higher echelons of care. These patients are often complex, requiring 24-hour monitoring, critical care skills, and a great deal of resources to treat. Obtaining evacuation is the highest treatment priority for these patients. This Clinical Practice Guideline (CPG) utilizes the minimum, better, best paradigm familiar to PFC, and gives medics of varying capabilities and resources options for treatment.

SEPSIS DEFINITIONS

Sepsis: Life-threatening organ dysfunction caused by a dysregulated host response to infection (Sepsis-3 definition, adopted by Surviving Sepsis Campaign in 2017).[1]

Septic Shock: Persistent hypotension requiring vasopressors to maintain mean arterial pressure (MAP) > 65 mmHg and having a serum lactate > 2 mmol/L despite adequate volume resuscitation.

Shock is one of the most common complications of severe injury or illness. Shock is separated into four different classes: 1) hypovolemic (including hemorrhagic), 2) cardiogenic, 3) obstructive, and 4) distributive. Septic shock is a form of distributive shock. The hallmark of managing shock is:

1. early recognition (including an awareness that the magnitude of injury or illness has the potential to lead to shock);
2. identification of the cause of shock; and
3. early, decisive treatment of the cause and initiation of cause-specific resuscitation.

Severe infection is often a greater risk than trauma in the PFC environment. Trauma-associated sepsis is an important subset of sepsis in the military population, with a potential for casualties to develop severe wound, respiratory, urinary, and bloodstream infections related to their initial injury and initial treatment procedures (IV/IO catheters, foley catheters, etc.). Up to 38% of trauma-related sepsis is bloodstream-related.[2] In the trauma patient, the manifestation of sepsis is often several days after initial presentation which makes sepsis particularly relevant in the PFC environment over a Role 1 with greater medevac capability.[3] Early antibiotic therapy and hemodynamic resuscitation with fluids and vasopressors are the key initial therapies for the septic patient. Source control is similarly critical and may require surgery. When this is not possible in the PFC environment, the patient must be supported and transported to a location with surgical capability as rapidly as possible.

SEPSIS MANAGEMENT GOALS

Sepsis management goals should include the following:[1]

- Early suspicion and recognition.
- Source identification.
- Early antimicrobial therapy.
- Resuscitation.
- Source control.
- Patient monitoring through trending patient information.
- Early telemedicine consultation.
- Evacuate to definitive care.

EARLY SUSPICION AND RECOGNITION

***GOALS**: Recognize sepsis and review the differential diagnosis; identify systemic infection before it progresses to decompensated shock; and identify patients who require evacuation.*

Infection may take many forms in initial presentation. Common examples include viral upper respiratory infections, gastroenteritis, urinary tract infections, cellulitis, and pneumonia. In addition, infections associated with travel, to include diarrhea, vector-borne diseases (malaria, dengue fever, etc.) and some respiratory pathogens will be particularly common in certain areas of the world. A comprehensive history of illness, to include travel history, should be obtained initially. Many infections may be managed adequately without evacuation or need for higher levels of medical care.

Differential diagnoses of presentations attributed to infections must be considered as well. Sepsis "mimics" anaphylaxis, gastrointestinal emergency, pulmonary disease including pulmonary embolism, metabolic abnormality including hyperthyroidism and adrenal insufficiency, toxin ingestion, toxin withdrawal, vasculitis, and spinal injury.[4] If the condition progresses to septic shock, "mimics" may include other causes of shock such as myocardial infarction, gastrointestinal bleeding, dehydration, heat injury, and hypovolemia secondary to gastrointestinal losses. If infection and sepsis are still prominent in the differential diagnosis after considering these other causes of shock, a focused assessment should be pursued, as detailed below. Any patient showing evidence of sepsis or septic shock should immediately be classified as an urgent evacuation priority.

HISTORY AND PHYSICAL EXAM

Minimum: "**SAMPLER**" history (**S**ymptoms/subjective complaints: **A**llergies to medications; **M**edications taken or prescribed; **P**ast medical and surgical history; **L**ast meal/oral intake; **E**vents leading up to presentation; and **R**ecent travel). Initial vital signs on presentation. Trending of vital signs (e.g., on PFC flow sheet found on the JTS Forms website) when looking for signs of severe infection are: fever or hypothermia; increase in heart rate; increase in respiratory rate; and, generally later rather than earlier, a decrease in blood pressure. Additionally, monitor mental status, SpO2, and capillary refill. Complete secondary survey physical exam. Look for Systemic Inflammatory Response Syndrome (SIRS), quick

Sepsis-related Organ Failure Assessment (qSOFA) criteria[5] and/or a high NEWS2 score[6], listed below. Look for potential sources of infection. Establish blood type of patient using an Eldon card.

- **Better**: Above, plus: Addition of simple labs: urine dipstick, BinaxNOW (malaria), i-STAT (or other point-of-care laboratory) values with vitals monitoring mentioned above. See i-STAT values in Appendix B. If available, monitor lactate.
- **Best**: Above, plus: Thick and thin smear (malaria), laboratory values (including lactate), culture data from likely source(s).

The more indicators of systemic infection, the higher the suspicion for the treating clinician. This is the "whole-patient" approach. A comprehensive problem list will be important to organize patient care. If sepsis is suspected, telemedicine should immediately be initiated (if possible) to help guide both diagnosis and therapy. Monitor vital signs constantly to guide treatments.

The Systemic Inflammatory Response Syndrome (SIRS) is a sign of an inflammatory reaction to a severe physiologic insult. Although no longer part of the definition of sepsis, SIRS is a useful tool in identifying patients at risk of acute decompensation. The SIRS criteria consist of four indicators:

1. tachycardia (heart rate >90 beats/minute)
2. tachypnea (respiratory rate >20 breaths/minute or PaCO2 < 32 mmHg)
3. fever or hypothermia (temperature >38°C/100.4°F or <36°C/96.8°F)
4. leukocytosis or leukopenia (white blood cell count >12,000/mm³, <4,000/mm³, or > 10% bands).[7]

A practitioner in an austere environment may not be able to measure all these indicators (especially WBC), but an understanding of these features of early sepsis may prompt earlier identification of disease and direct more-timely therapeutic interventions.

qSOFA is the more recent sepsis screening tool; it seeks to identify patients at an increased risk of death.[5] The presence of two or more of the following three qSOFA indicators should increase the clinician's index of suspicion for sepsis: 1) altered mental status, 2) tachypnea (>22 breaths per minute), and 3) hypotension (SBP <100mmHg).

WARNING

Hypotension is a late sign in sepsis. ***Do not wait for blood pressure to fall before initiating treatment and resuscitation*** *in a patient who is showing multiple signs of systemic infection (fever, tachycardia, tachypnea, altered mental status, decreased urine output). Delaying intervention until blood pressure falls can make it harder to get the systemic inflammatory reaction under control and increase risk of death.*

A more in-depth tool used in the prediction of ICU admission shown to be more effective than qSOFA is the NEWS2 score which is based on only clinical measurements and assessment. NEWS2 incorporates more variables, making it less "quick" than the qSOFA. Although not applied in clinical practice to sepsis evaluation exclusively, it may be a very useful tool in predicting clinical deterioration. The clinical variables required to compute a NEWS2 score include respiratory rate, hypercapnic respiratory failure (yes/no), oxygen saturation (and need for supplemental oxygen), temperature, heart rate, systolic blood pressure, and general level of consciousness. These parameters are recorded using a scale system, assigning points between 0-3 for each parameter. This tool has been shown to be superior to qSOFA for detecting sepsis with organ dysfunction in the emergency department.[8]

The following clinical assessment – history and physical exam findings – should raise the suspicion for early sepsis:

SUBJECTIVE ASSESSMENT

- Patients with sepsis may report the below complaints, with no other obvious non-infectious source (i.e. bleeding, traumatic brain injury, heat injury).
- Chills and rigors
- Confusion
- Malaise: feeling weak, with little or no energy

OBJECTIVE ASSESSMENT

Physical exam findings of patients with sepsis may include:

- Concerning (or obvious) sources of infection:
  - Wound(s) displaying signs of infection (i.e. pain, redness warmth, purulent drainage, swelling).
  - Indwelling catheters (IV/IO/urinary) or devices in less-than-sterile/field environment.
- Temperature of >38°C/100.4°F or < 36°C/96.8°F.
- Cool skin, cyanosis, delayed capillary refill time (>3 seconds).
- Abnormal vital signs, particularly tachycardia (> 90 bpm), sustained hypotension (systolic blood pressure <90 mmHg), tachypnea (>20/min).
- Low urine output (oliguria).
- Altered or worsening mental status (confusion, lethargy).
- Rash, purpura (meningococcemia, Rocky Mountain spotted fever, other rare etiologies).
- Meets the SIRS Criteria; qSOFA criteria and/or high NEWS2 score (see above).
- Lab specific values. (See Appendix B.)

***NOTE**: Typical symptoms may not be present in some patient populations. Signs of sepsis may be attenuated and/or muted in the elderly, delayed manifestation in the very young, or masked in pregnancy due to the normal physiologic changes and absence of a febrile response in up to 50% of pregnant patients.*

SOURCE IDENTIFICATION

***GOAL**: Locate probable cause of infection to most appropriately address the source.*

Approach to Source Identification:

- Gather a complete patient history of recent and/or ongoing illnesses.
- Conduct a thorough head-to-toe exam to look for evidence of infection – wounds, bites, etc. Be sure to examine the genitourinary and perirectal areas, as these are common sites of missed infections.
- Perform rapid malaria, dengue, and point of care source tests if in an endemic area, as well as urine dipstick and i-STAT labs.[9]

Sepsis may be of bacterial, fungal, viral, or parasitic origin. Bacterial infections are the most common causes of sepsis followed by parasitic (mainly malaria), viral (e.g., dengue, influenza, COVID-19), and finally, fungal diseases.[10] The prevalence of each is directly related to a given region.[11] Identifying the cause of sepsis is challenging in the PFC environment where advanced diagnostic tests are unavailable, and antiviral and antifungal therapies are rarely available. This CPG focuses on the most common etiologies of sepsis, and the treatments of those forms of sepsis that the austere provider can reasonably manage. Advanced preparation is important, and a medical area study and/or medical threat-model analysis should be done prior to traveling to gather data on microbes specific to that given region.

For a given region, bacterial sepsis is most often due to a limited number of common pathogens to include streptococci (including *S. pneumoniae*, which causes pneumonia and meningitis), Staphylococci, *Neisseria meningitidis* (also a cause of meningitis, particularly common in regions of sub-Saharan Africa), and gram-negative bacteria arising in the gut. Treatment of many of these infections is complicated by rising rates of antibiotic resistance worldwide.[12]

Malaria must be considered high on a differential diagnosis list as a leading cause of any febrile illness in an endemic region. In the typical patient from an industrialized country without prior exposure to the infection, malaria can be rapidly fatal in the absence of early and specific therapy.[13]

A significant minority of sepsis cases (up to 15%) are due to fungal infections. *Candida* species are normal flora in the human gut and vaginal canal and are the most common causes of fungal sepsis, followed by invasive mold infections such as *Aspergillus* and by endemic fungi causing community-acquired disease, including *Histoplasma*, *Coccidioides*, and *Talaromyces*. In the PFC environment, *Candida* infections may follow penetrating abdominal trauma with perforation of the gut, while invasive molds may arise after blast injuries with devitalized tissue (such as after a high lower extremity amputation). Therapeutic options for both of these scenarios are very limited in a PFC setting.

Because war wounds are considered grossly contaminated wounds, they must be attended to meticulously. Unattended wounds can lead to acute infection and sepsis within days (or possibly within hours for very large and contaminated wounds).[14] Quality wound care is essential to infection and sepsis prevention as detailed in the *JTS Acute Traumatic Wound Management in the Prolonged Field Care Setting CPG*.[15]

TREATMENT

ANTIMICROBIAL THERAPY

***GOAL**: Use targeted and most appropriate antibiotic therapy when possible.*

Antibiotic regimens: See the *JTS Acute Traumatic Wound Management in the Prolonged Field Care Setting CPG*.

- **Minimum**: Moxifloxacin 400 mg PO daily (or levofloxacin 750 mg PO daily to provide better coverage of bacteria found in wet terrain/jungle environment).
- **Better**: Ertapenem (Invanz) 1 gram IV/IO once per day (q24 hrs) given over 5 to 10 minutes or IM (not preferred), OR ceftriaxone (Rocephin) 2 grams IV/IO given over 10 minutes q24hrs.
- **Best**: Ceftriaxone (Rocephin) 2 gm IV/IO q24 hrs given over 30 minutes, PLUS vancomycin (Vancocin) 15 mg/kg IV/IO q12 hrs. (given after ceftriaxone, given over 2 hours) PLUS metronidazole (Flagyl) 500 mg IV/PO/IO q8hrs, given over one hour.

ANTIPARASITIC REGIMENS

If sepsis is suspected in a malaria-endemic area and there is no other clearly identified source, conduct a malaria point-of-care test BINAX Now® and thick and thin smears, if available. If positive, administer both antibiotics and antimalarials. If unable to test for malaria, empiric antimalarial therapy can also be considered. Additionally, in a malaria-endemic area, when a patient is initially unresponsive to antibiotic therapy, add antimalarials.

- **Minimum:** Atovaquone/progauanil (Malarone) 4x3 regimen – 4 tablets PO once a day for 3 days.
- **Best:** Artemether/lumafantrine (Coartem) 4 tablets PO initially, then 4 tablets after 8 hours, then 4 tablets PO twice daily for 2 more days (24 tablets total).
- **Severe Malaria:** The optimal treatment for severe malaria (defined as malaria with associated findings such as altered mental status, acidosis with lactate >5 mmol/L, prostration, hypoglycemia, parasitemia >10%, hemoglobin <7 g/dL, creatinine >3 mg/dL, pulmonary edema, shock, or pathologic bleeding), the drug of choice is IV artesunate 2.4 mg/kg IV/IO at 0, 12, 24, and 48 hours (4 doses), followed by 3 days of either Malarone (4 tablets PO, for 3 days) or Coartem (4 tablets initial dose, followed by 4 tablets given 8 hours later, followed by 4 tablets twice daily for the next 2 days; 24 total tablets).

- ***NOTE 1:** Although artesunate may be available in tropical countries, the quality of formulation may not be at FDA standards and telemedicine assistance and initiation of medevac should be initiated for severe malaria.*
- ***NOTE 2:** If unable to obtain artesunate, we recommend Coartem or Malarone with teleconsultation assistance and initiation of medevac.*

ANTIFUNGAL REGIMENS

Do NOT administer without telemedicine. When advised, antifungal drugs are administered in conjunction with the antibiotic regimen mentioned above.

- **Minimum**: Fluconazole 400 mg PO or IV daily (note that PO is equipotent to IV).
- **Better/Best**: Due to the complexity and toxicity of many anti-fungal medications, this CPG will not extend beyond the minimum recommendation.

RESUSCITATION

***GOAL**: Meet perfusion goals by replenishing intravascular volume and using adjunctive medications (i.e. vasopressors) as indicated.*

***CAVEAT: If you are treating sepsis in the setting of trauma, resuscitate with whole blood or blood component therapy as you would for trauma. (See *JTS Damage Control Resuscitation – PFC CPG*.[16])

FLUID RESUSCITATION CONSIDERATIONS

- **Minimum**: In the absence of IV/IO capability, have the patient drink water and monitor urine output with a goal of averaging 0.3-0.5 mL/kg/hr. Include an oral rehydration solution for those patients who cannot consume food but can drink water (use either proprietary mixtures or fabricated – 6 teaspoons of granulated sugar with ½ teaspoon of table salt in 1 liter of water. See the *JTS Nursing Intervention – PFC CPG*.).[17] Rectal fluids (begin at 100mL/hour and increase rate to a maximum of 500mL/hour) may be used for patients who cannot tolerate oral fluids. Use oral rehydration solution mentioned above for rectal administration.
- **Better**: IV/IO crystalloid bolus (up to 30mL/kg of IV crystalloid within the first 3 hours) until a urine output of 0.3-0.5 mL/kg/hr is reached. This output can be measured using any external measuring device – water bottles, graduated collecting bottle, etc.
- **Best**: The same fluid resuscitation strategy as above with the addition of a urinary catheter in place for more precise measuring of urine output (ensure the first catch from a recently placed catheter is discarded and not documented in total output calculations).

The first step in resuscitation of the sepsis/septic shock patient is the replenishing of intravascular volume ("fill the tank"), ideally with IV/IO administration of crystalloids. The preferred fluids for IV/IO resuscitation in order of preference are: Lactated Ringers (LR) (or Plasmalyte A), then normal saline. Chloride-restricted IVF (LR/Plasmalyte A) are ideal for larger boluses (>3-4L) or ongoing resuscitation.[18] When administering large amounts of IV/IO fluids, monitor for over-resuscitation and pulmonary edema, indicated by lung auscultation (rales or "wet lungs"), increased work of breathing/decreased oxygen saturations, and evidence of edema on a plain chest film or ultrasound (if available). Urine output, with a goal of 0.3-0.5mL/kg/hr, should indicate adequate fluid resuscitation in a patient with normal kidney function, however, some patients in septic shock may have acute kidney injury (AKI). As such, initial bolus of crystalloids should not exceed 2-3 liters maximum, and further fluid administration should be based on blood pressure and measures of perfusion (capillary refill), as well as measured losses (gastrointestinal, etc.). Higher urine output (> 0.5mL/kg/hr) indicates over-resuscitation. Additionally, if labs are available, resuscitation to a normalized lactate level would be further indication

of positive improvement. It is also important to monitor serum electrolytes as abnormalities of sodium and potassium levels are particularly common during fluid resuscitation.

Negative trends of sepsis-induced hypoperfusion may include low and/or steadily decreasing SBP and/or delayed capillary refill (>3 seconds), an important indicator for measuring perfusion. In response to negative shifts in the patient's hemodynamic status – a SBP that drops below 90 mmHg, and/or a Mean Arterial Pressure (MAP) that drops below 65 mmHg – initially increase the fluid resuscitation by 20 percent (watching for signs of over-resuscitation above).

***Key point**: Over-resuscitation carries considerable risk including acidosis, dilution of clotting factors, pulmonary edema, ascites, hypernatremia and peripheral edema. If the patient's blood pressure and organ dysfunction (e.g., urine output and mentation) is not responding to recommended maximum resuscitation of 30 mL/kg over the first 2-4 hours of initiating treatment, seek telemedicine guidance on whether to cautiously give more fluids or start vasopressors.*[19]

DRUG CONSIDERATIONS

Vasopressors: Consider, if, after initial fluid resuscitation (reaching initial urine output goals or maximum of 30mL/kg IVF bolus in the first 2-4 hours), there is no observed positive change in SBP, MAP, urine output and/or mentation (fluid-refractory shock). If vasopressors are used after initial fluid resuscitation, do not administer more fluids as this can likely cause dangerous fluid shifts; implement telemedicine. ***Consider starting low dose vasopressors ONLY under guidance of telemedicine consultation**, with norepinephrine (first choice) or epinephrine (alternate)*[20] See Appendix F.

SOURCE CONTROL

***GOAL**: Eliminate the source of infection.*

Some infection sources are treated only with antibiotics, while others may require surgery to remove or drain the infection source. A full patient exam should be performed to look for sources of infection that may not have been identified on the initial patient survey and serial exams should be performed as part of ongoing patient assessment to track physical signs of infection spread or response to therapy. With wound sepsis, quality wound care is critical to infection and sepsis treatment and prevention as previously detailed in the *JTS Acute Wound Management - PFC CPG.*

Any identified potential infection sources such as foreign bodies, old indwelling catheters (to include IV/IO, urinary, etc.) and dead or dying tissue must be evaluated and attended to immediately. All previously inserted urinary or other indwelling catheters and IV/IO catheters should be removed and replaced if possible. Those that are not needed to immediately care for the patient should be considered for removal. All wound dressings should be removed, and any sign of infection requires surgical wound exploration. All dead infected tissue must be removed, up to and including amputation when needed. Any abscesses or infected spaces must be completely drained. Any suspected intrathoracic or intraperitoneal infection sources must be attended to by a surgeon urgently. Always initiate antibiotics and fluid resuscitation prior to attempting surgical interventions.

Aggressive and adequate surgical source control is essential to the patient's survival. Obtain telemedicine consultation from a surgeon.

MONITOR THE PATIENT

Monitor the patient for trend available vital signs, urine output, capillary refill, and adjuncts (ultrasound and/or labs if available).

***GOAL**: Establish a baseline and measure response to interventions.*

- **Minimum**: Serial vital signs measurement, mental status assessment, and urine output. Vital signs trends and interventions recorded on flowsheet.
- **Better**: Add point-of-care lactate every 6 hours until normal.
- **Best**: Add ultrasound monitoring to assess and trend inferior vena cava (IVC) and left ventricular (LV) filling, decrease in "hyperdynamic" cardiac physiology.

Employing focused, goal-oriented interventions as early as possible has shown to decrease mortality. The following goals will direct treatment initiatives. Medical providers should develop and prioritize a problem list with an accompanying treatment-solutions plan to meet the below therapy goals.

- **Systolic blood pressure (SBP) > 90 mmHg and/or palpable radial pulse** (if blood pressure monitoring is not available). SBP is the most appropriate and feasible modality for monitoring a patient's perfusion status.
- **Mean Arterial Pressure (MAP) > 65**. MAP is manually calculated using the formula (Systolic BP + (2 x Diastolic BP))/3. Most electronic monitors will automatically calculate the MAP. At times, the MAP may be adequate even when the SBP is low, however, SBP may be used when it is easier to monitor.
- **Capillary refill** is an easy physical exam skill and important indicator of adequate perfusion as a high-fidelity marker for effective resuscitation. It should be performed and recorded as a trend at least every 30 minutes for the unstable septic patient. The proper way to measure capillary refill is to apply pressure down on the fingernail until it blanches (turns white), and after the removal of the pressure, time the nail's return to normal color as compared to the other nails. Normal values are a return to baseline color in three seconds or less. Longer times indicate normal perfusion has not been restored.
- **If a soft tissue infection is suspected,** inspect and monitor the identified site (e.g., cellulitis) for improvement. Use a marker to outline any redness; time and date it. Monitor for any progression beyond the marked lines. If redness worsens after 24 hours or failure to improve within 48 hours, consider changing antibiotics or the need for surgical debridement after consulting telemedicine.
- **Urine output (UOP)** should be maintained at an average of 0.3-0.5mL/kg/hr.
- **Perform and repeat available labs** as indicated. Diagnostics: urine dipstick, malaria tests. Trend: i-STAT, lactate.
- **Initiate telemedicine early** and often and report trends.
- **Monitor overall respiratory status**. Many patients who are critically ill with sepsis will need ventilatory support at some point in their management – see the *Airway Management - PFC CPG*,[21] as well as the PFC reference paper: *"MSMAID" Applying an Anesthesia Checklist to SOF Medicine*.[22] Always be prepared to manage a complex airway with septic patients. Also, see the *CCAT Mechanical Ventilation CPG.* [23]

EARLY TELEMEDICINE

***GOAL**: Gather appropriate and complete information and enlist the help of a critical care and/or surgical expert early in your management.*[24]

The following information, if obtainable, should be prioritized to enable the most effective telemedicine support: subjective comments; objective – vital signs (HR, RR, Systolic BP, MAP, urine output); mental status; skin exam, lactate (if available); treatments administered or available – antibiotics; any other drugs, and the amount and type of fluids given so far.

- Ensure the complete medical history and documentation of any preceding events.
- Communicate capabilities available where you are managing the patient (e.g., by completing the "capabilities checklist" on the *PFC WG Telemedicine Template* on prolongedfieldcare.org and emailing/texting if possible before calling the consultant).
- Document any infected wounds, bites, or other potential sources of infection, etc. Send photographs or real-time video if possible.

EVACUATE TO DEFINITIVE CARE

***GOAL**: Patients identified as being septic should be assigned the highest priority of evacuation to higher levels of medical care.*

Patients with sepsis or with conditions concerning for the deterioration to sepsis will be best managed in a clinical setting conducive to monitoring and addressing multi-organ failure and associated complications. Also, see the *JTS Nursing Intervention - PFC CPG* and *JTS Analgesia and Sedation Management - PFC CPG*.[25]

NUTRITION CONSIDERATIONS

Septic patients are most often in a hypermetabolic state due to the body's efforts to fight off the infection. Nutrition is not the most important consideration in the early treatment. However, given that some patients may require continued treatment in an austere environment, may have pre-existing malnutrition, or may present for treatment after being septic for a period of time, attention must be paid to the patient's nutrition as a part of a treatment plan. This can be difficult if the patient is nauseated and/or vomiting, has an intraabdominal source of infection, resources are severely limited, or the patient's mental status is not conducive to eating and drinking.

Most patients do not require nutritional support when evacuation is anticipated within 72 hours. When evacuation is delayed beyond 72 hours or not possible, adequate nutrition should be sustained as outlined below.

***GOAL**: Goal 25-30kcal/kg/day + 1-1.2gm/kg protein. Most patients with a normal mental status can feed him or herself without the placement of a feeding tube.*

1. Enteral nutrition (oral or administered by orogastric or nasogastric tube) should be withheld in hemodynamically unstable patients (i.e. those on high or increasing doses of vasopressors) due to the risk of causing ischemic GI injury to include perforation.
2. Nasogastric Tube (NGT) should be placed in patients deemed in critical for gastric decompression. If medical evacuation is significantly delayed (greater than 48 – 72 hours) or the patient has been without significant caloric intake for over 3 days (due to delayed presentation), consider starting enteral nutrition (orally if they can take PO safely, via tube if not). If the patient requires continuous vasopressors, avoid the bolus nutrition sources, and opt for a lower volume hourly rate of infusion (10 – 20cc/hr.).
3. At a minimum, confirm presence of gastric placement with auscultation over both lung fields and the abdomen, along with aspiration of gastric contents. Best recommendation is obtaining plain film radiography to confirm proper placement PRIOR to instilling any substances through the tube.
4. Ensure presence of normal bowel sounds prior to initiating any enteral feeding.
5. Enteral feeding is contraindicated in the presence of severe abdominal distension, abdominal pain and/or gastro-intestinal bleeding.

Oral Feed vs Tube Feed

If a patient has a normal mental status they likely can take oral nutrition - do not put a tube down their nose. If they cannot cooperate or tolerate oral feeds, and evacuation is not likely or not possible within 72 hours, consider tube feeds. If tube feeds are initiated without an ability to obtain x-ray verification of placement, monitor for signs of misplacement or GI obstruction very closely (e.g., nausea, increasing abdominal distension or pain) and stop feeding if they occur. Patients require continuous hydration, but those who receive adequate hydration will not experience clinically significant adverse effects from starvation for several days to over a week.

Severe Malnutrition

If someone has signs of severe malnutrition (e.g., local nationals in setting of famine, hostages), obtain telemedicine consultation before starting enteral nutrition. Refeeding syndrome is a life-threatening metabolic and electrolyte derangement that can develop from feeding severely malnourished patients too much, too quickly. It is very difficult to detect in the PFC environment. The first sign may be cardiac collapse from electrolyte derangements which is nearly impossible to resuscitate.

6. Meal supplement drinks are sufficient. 1x Muscle Milk Light bottle contains 150kcal and 28gm protein in 500mL.
7. A more concentrated alternative is to use commercially available protein powder (with similar caloric/protein content per scoop) at 1/4 the recommended concentration and mix until no clumps are visible.
8. Administer tube feeds in small volume boluses (e.g., 60mL via Toomey syringe) 2-4 hours for a goal of 1gm/kg/day protein content.
9. If vomiting or increased abdominal distension occur, hold tube feeds for 6 hours and then try again.
10. For more information, see *JTS Nutrition Support Using Enteral and Parenteral Methods CPG*.[26]

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Casualties receiving PFC or Prolonged Casualty Care (PCC).

INTENT (EXPECTED OUTCOMES)

Prehospital documentation is received by JTS on all PFC and PCC patients.

PERFORMANCE/ADHERENCE MEASURES

- Sepsis patient with >2hr prehospital care that arrives intubated to Role 2 or 3.
- Sepsis patient with >2hr prehospital care requiring dialysis at Role 3 or 4.
- Sepsis patient with >2hr prehospital care that dies in first 30 days.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- PFC Flowsheet

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: SEPSIS PATIENT MANAGEMENT CHECKLIST

If sepsis is suspected, the following checklist should be employed to begin treatment and set up a safety net for ongoing patient care:

- ☐ Placement of 2 IV access points (Large bore IV/IO).
- ☐ Collect blood cultures x2 (if available).
- ☐ Start IVF with goal resuscitation of adequate urine output, up to maximum bolus of 30ml/kg (usually about 2-3 Liters). See Resuscitation recommendations.
- ☐ Consider placement of advanced monitoring equipment (if available).
- ☐ Place a Foley catheter.
- ☐ Monitor all vital signs and continuously trend heart rate, blood pressure, respiratory rate, and mental status every 15 minutes on a flowsheet. (See *https://jts.health.mil/index.cfm/PI_CPGs/cpgs*). Temperature and urine output should be documented hourly.
- ☐ Place on oxygen if indicated and available (for SpO2 < 90%).[1]
- ☐ Ensure a secure airway is in place, or the equipment for a definitive airway is on hand along with the elements of M.S.M.A.I.D. (See *JTS Airway Management for Prolonged Field Care CPG*.)
- ☐ Search for the source of infection. Address this as appropriate (wound care, removal of infected catheters, surgical consultation, etc.)
- ☐ Give the most appropriate antibiotics.
- ☐ Call telemedicine consultant early and often.
- ☐ Take/Give Approach: Take – Vital signs, neurologic assessment, wound/ skin infection exams, serum lactate level, urine output (Foley catheter), rapid tests. Give – Antibiotics, Fluids, Oxygen (if available), Vasopressors (with telemedicine).
- ☐ If providing nutrition, monitor for signs of GI upset or obstruction: nausea, abdominal pain, and abdominal distension.

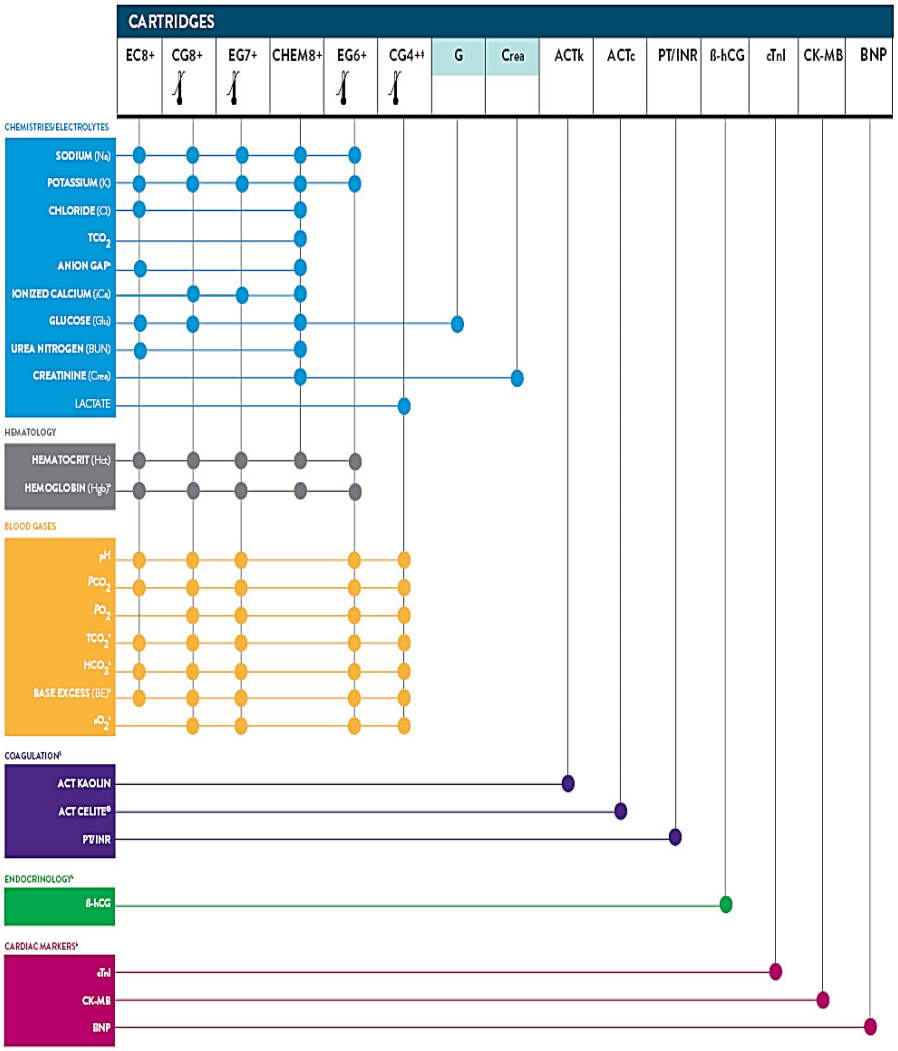
APPENDIX B: I-STAT LAB VALUES

The laboratory values shown in the table are a composite of the laboratory values, by cartridge, that i-STAT has available. Lab values that may indicate sepsis are elevated lactic acid (lactate), procalcitonin (PCT), and white blood cell (WBC) count. See the *i-STAT Portable Blood Analyzer in Austere Locations CPG*. The values represent a peripheral venous collection. Lab results should be compared to the i-STAT normal range shown in the reference table. *(Preprinted with permission from Abbott Labs, July 2020)*



EXPECTED VALUES			
ANALYTE	REPORTABLE RANGE	REFERENCE RANGE, ARTERIAL	REFERENCE RANGE, VENOUS
Sodium (Na)	100-180 mmol/L	138-146 mmol/L	138-146 mmol/L
Potassium (K)	2.0-9.0 mmol/L	3.5-4.9 mmol/L	3.5-4.9 mmol/L
Chloride (Cl)	65-140 mmol/L	98-109 mmol/L	98-109 mmol/L
TCO_2	5-50 mmol/L	23-27 mmol/L	24-29 mmol/L
Anion Gap[a]	(-10)-(+99) mmol/L	10-20 mmol/L	10-20 mmol/L
Ionized Calcium (iCa)	0.25-2.50 mmol/L	1.12-1.32 mmol/L	1.12-1.32 mmol/L
Glucose (Glu)	20-700 mg/dL	70-105 mg/dL	70-105 mg/dL
Urea Nitrogen (BUN)	3-140 mg/dL	8-26 mg/dL	8-26 mg/dL
Creatinine (Crea)	0.2-20.0 mg/dL	0.6-1.3 mg/dL	0.6-1.3 mg/dL
Lactate[b]	0.30-20.0 mmol/L	0.36-1.25 mmol/L	0.90-1.70 mmol/L
Hematocrit (Hct)	15-75 %PCV	38-51 %PCV	38-51 %PCV
Hemoglobin (Hgb)[a]	5.1-25.5 g/dL	12-17 g/dL	12-17 g/dL
pH‡	6.50-8.20‡	7.35-7.45	7.31-7.41
PCO_2‡	5-130 mmHg‡	35-45 mmHg	41-51 mmHg
PO_2‡	5-800 mmHg‡	80-105 mmHg	
TCO_2[a]	5-50 mmol/L	23-27 mmol/L	24-29 mmol/L
HCO_3[a]	1.0-85.0 mmol/L	22-26 mmol/L	23-28 mmol/L
Base Excess (BE)a	(-30)-(+30) mmol/L	(-2)-(+3) mmol/L	(-2)-(+3) mmol/L
sO_2[a]	0-100 %	95-98 %	
ACT Kaolin	50-1000 Seconds	74-137 Seconds (Prewrm)	74-137 Sec. (Prewrm)
ACT Celite®	50-1000 Seconds	74-125 Seconds (Prewrm)	74-125 Sec. (Prewrm)
PT/INR	0.9-8.0 INR[c]		
ß-hCG	5.0-2000.0 IU/L		<5 IU/L
cTnI	0.00-50.00 ng/mL		0.00-0.08 ng/mL[d]
CK-MB	0.0-150.0 ng/mL		0.0-3.5 ng/mL[e]
BNP	15-5000 pg/mL		<15-50 pg/mL[e]

[a] Calculated-note that TCO_2 is measured on CHEM8+ cartridge and calculated on all others.

Celite is a registered trademark of Celite Corporation, Santa Barbara, CA for its diatomaceous earth products.
= CLIA waived: granted waived status for lithium heparin whole-blood venous samples only collected in a lithium heparin evacuated tube.

‡ Reportable ranges for the (blue) CG4+ cartridge are: pH = 7.00-7.70; PO_2 = 15-530; PCO_2 = 15-130
[c] Performance characteristics have not been established for INR values over 6.0.
[d] Represents the 0-99% range of results.
[e] Represents the 0-95% range of results.

APPENDIX C: ABNORMALITIES DETECTION

Urine Dipstick: A dipstick — a thin, plastic stick with strips of chemicals on it — is placed in the urine to detect abnormalities. The chemical strips change color if certain substances are present or if their levels are not normal. The color variation often is indicative of how severe the abnormality is. Urine dipsticks are another tool and indicator to measure a patient's well-being. Its values should be included in the "whole patient" approach to the medical evaluation. A dipstick test checks for:

- **Acidity (pH).** The pH level indicates the amount of acid in urine. Abnormal pH levels may indicate a kidney or urinary tract disorder or a potential systemic infection – sepsis.

- **Concentration**. A measure of concentration, or specific gravity, shows how concentrated particles are in your urine. A higher than normal concentration often is a result of not drinking enough fluids. In the setting of sepsis, it is a sign of clinically significant volume depletion.

- **Protein**. Low levels of protein in urine are normal. Small increases in protein in urine usually are not a cause for concern, but larger amounts may indicate a kidney problem.

- **Sugar**. Normally the amount of sugar (glucose) in urine is too low to be detected. Very high levels of glucose, especially when ketones are also elevated and pH decreased, can indicate diabetic ketoacidosis which may mimic sepsis. This can occur in individuals who were not previously aware they are diabetic and is a life-threatening condition, obtain telemedicine consult.

- **Ketones**. As with sugar, high levels of ketones detected in your urine could be a sign of diabetic ketoacidosis. Ketones in urine may also be a sign of malnutrition and protein-calorie deficit in the septic patient that should prompt consideration of starting caloric intake or enteral nutrition.

- **Bilirubin**. Bilirubin is a product of red blood cell breakdown or bile synthesized in the liver. Normally, bilirubin is carried in the blood and passed into the liver, where it is conjugated and becomes part of bile. Bilirubin in your urine may indicate liver damage, bile duct obstruction, or hemolysis (e.g., distributed intravascular coagulopathy).

- **Evidence of infection**. If either nitrites or leukocyte esterase — a product of white blood cells — is detected in your urine, it may be a sign of a urinary tract infection or systemic infection – sepsis.

- **Blood**. Blood in your urine requires additional testing — it may be a sign of kidney damage, infection, kidney or bladder stones, kidney or bladder cancer, or blood disorders.

APPENDIX D: MALARIA RAPID TEST & MICROSCOPY

Reprinted with permission from Abbott Labs, July 2020.

BINAXNOW®

The BinaxNOW® Malaria test is a rapid and simple diagnostic test that can differentiate a deadly P. falciparum infection from a pan-malarial infection caused by P. vivax, P. ovale or P. malariae in 3 simple steps using 1 reagent. Typically, the limiting factor for mass-testing is the amount of reagent on-hand.

- Results appear in 15 minutes
- Sensitivity: 99.7% (P.f.); 93.5% (P.v.)
- Specificity: 94.2% (P.f.); 99.8% (P.v.)

Directions for BinaxNOW Use

Step 1	Step 2	Step 3	Step 4
Apply 15uL of blood to the bottom half of the purple pad.	Apply 2 drops of Reagent to the white pad immediately below where the blood was applied.	Apply 4 drops of Reagent to the pad located at the top of the left-hand side of the test card.	When the blood sample reaches the base of the white absorbent pad at the top of the test strip, close device and read after 15 minutes.

Binaxnow Results Table

Positive P. Falciparum Mixed	Positive P. Falciparum	Positive P. Vivax P. Ovale P. Malariae	Negative

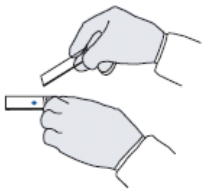
MICROSCOPY

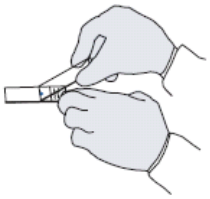
When done correctly, microscopic examination of thick and thin blood smears is the most reliable test for malaria. Blood smears are taken most often from a finger prick and a few drops of blood. Thick and thin blood smears allow direct visualization of parasites and their reproductive derivatives – schizonts in malaria. See *U.S. Department of Defense. Special Operations Forces Medical Handbook. 2011.*

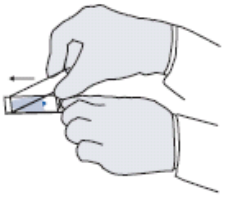
- A thick blood smear is a drop of blood on a glass slide. Thick blood smears are most useful for detecting the presence of parasites, because they examine a larger sample of blood. (Often there are few parasites in the blood at the time the test is done).
- A thin blood smear is a drop of blood that is spread across a large area of the slide. Thin blood smears help providers discover what species of malaria is causing the infection.
- The two smears can work in tandem if a thick and thin smear is made. This method allows the provider to observe both thick and thin smears and find the blood density that is most likely to yield visualization of the parasite to the given observer.
- If a high index of suspicion exists for malaria in a given patient, but microscopy does not reveal an obvious malarial infection, serial thick and thin smears can be repeated every 8 or 24 hours depending on the severity of the case.

Making a thick and thin smear

Step 1	Step 2	Step 3	Step 4	Step 5
Bring a clean spreader slide, held at a 45-deg. angle, toward the drop of blood on the specimen slide.	Wait until the blood spreads along the entire width of the spreader slide.	While holding the spreader slide at the same angle, push it forward rapidly and smoothly.	Wait until the smear is completely dry. Fix the thin film with 100% (absolute) methanol.	When the film is completely dry, stain with 7.5% Giemsa stain for 15 minutes.
				







The thick and thin film should be air-dried, fixed with 100% (absolute) methanol, and allowed to dry before staining with 7.5% Giemsa stain for 15 minutes. Plasmodium parasites are always intracellular, and they demonstrate, if stained correctly, blue cytoplasm with a red chromatin dot (see images 1-4 below). Common errors in reading malaria films can be caused by platelets overlying a red blood cell, concern regarding missing a positive slide, and misreading of artifacts as parasites. The slide is best read by starting at the thin end of the slide and moving it towards the thick side until the RBCs are side by side, but NOT overlapping. This will give the observer the highest concentration of RBCs in view, giving him or her the highest probability of identifying the parasite. Move the slide along this plane of side-by-side RBCs to accurately rule out or in a malarial parasitic infection (Image 1). If the malaria parasite is identified, begin appropriate anti-malaria/anti-parasite treatment immediately in conjunction with the antibiotic therapies (minimum, better, best) mentioned above.

Malaria parasites

Images 2-4 demonstrate plasmodium within cells with the characteristic "signet ring" sign.

Image 1. *Malaria parasites are identifiable by their blue stain inside the cells. This picture shows an excellent example of a properly prepared thick/thin smear – the cells are side by side without overlapping.*

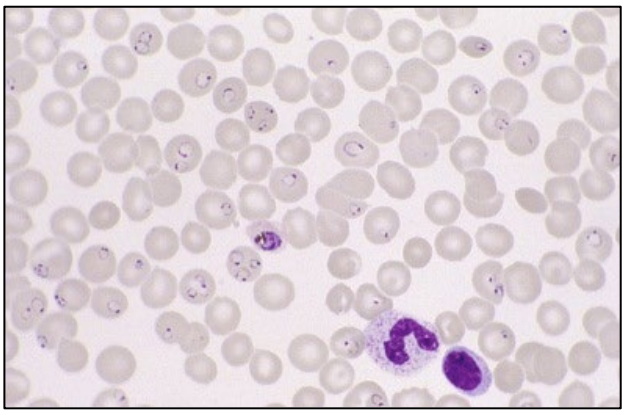


Image 2

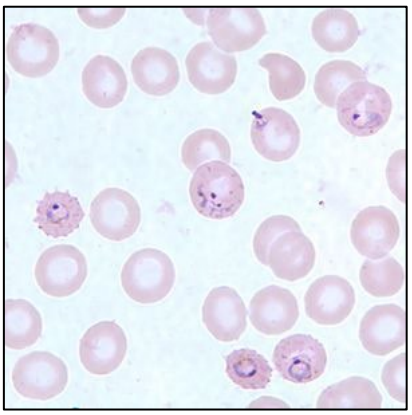

Image 3

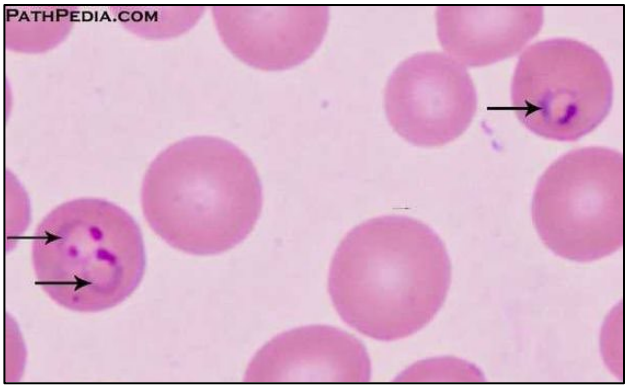

Image 4

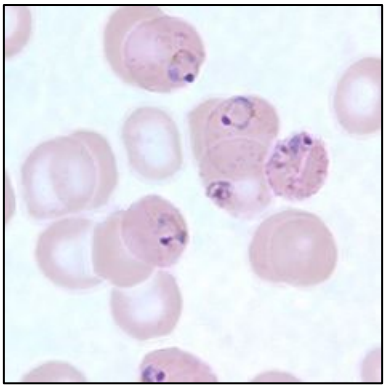

Images 2-4 from cdc.gov; image 3 from pathpedia.com.

APPENDIX E: LACTATE

Lactate can be measured with the CG4 i-STAT cartridge. This specific cartridge must be stored in a temperature-controlled environment. Lactate can also be measured using a lactate-specific device but many are not approved for medical management of critical patients.[1]

Adding lactate to other resuscitation endpoints is beneficial, however patients should be monitored using a "whole patient" approach. He or she could be doing well clinically with an adequate blood pressure and capillary refill, good urine output, and down-titrating vasopressors, but continues to have a persistently elevated lactate level. There are many reasons for this, some of which do not require a clinical response, only further monitoring. Lactate levels have a direct impact on a patient's pH (acidosis), however the main adverse effects of acidosis are a) decreased cardiac output and vascular "tone," which will be seen as persistent hypotension and b) impaired coagulation, which will be seen as bleeding despite adequate blood product resuscitation and source control. In general, these effects do not occur at a pH above 7.2 (which does not correlate directly to a specific lactate level).

If lactic acid levels are available, they should be integrated into patient monitoring as follows:

- Trend lactic acid levels at a frequency of every 4 – 6 hours. Lactate improvement will lag behind improvement in vital signs, mental status, and urine output.
- If patient is under-resuscitated, or resistant to resuscitation, vital signs and organ dysfunction assessments will continue to be abnormal, with no appreciable response, and lactate will remain elevated.
- If other markers of resuscitation are improving and the patient is clinically improving, but lactate is not decreasing or is increasing, it could be an indication of tissue reperfusion (flushing out vascular beds that have not been perfused due to shock). Keep trending lactate, and if it remains elevated or is increasing, this could be an indication of a source of infection that has not been adequately addressed and may require a change in antibiotic regimen, and/or surgical intervention. Obtain telemedicine consult.

1. *Bonaventura JM, Sharpe K, Knight E, et al. Reliability and accuracy of six hand-held blood lactate analysers. J Sports Sci Med. 2015 Mar 1;14(1):203-14.*

APPENDIX F: EPINEPHRINE (NOREPINEPHRINE) - VASOPRESSOR GUIDE

Consider starting low dose vasopressors – either epinephrine, or norepinephrine if available -after 30mL/kg of IVF and no changes in MAP, urine output or mentation.[1] Epinephrine can improve blood pressure by a) vasoconstriction and b) increasing cardiac contractility, thus improving cardiac output.[2] Vasopressors are rarely used outside of a critical care setting and use in an austere environment indicates a dire situation and must be monitored extremely closely. The dose of either epinephrine or norepinephrine are the same for drip calculations. Epinephrine is presented as it is far more available in austere practice settings. These are presented as low-dose starting points and any adjustments should be directly under telemedicine guidance. Of note: if monitoring, levels of lactate may rise with use of epinephrine as a vasopressor.

Epinephrine, as an IV or IO push-dose: A 10mL syringe consisting of 9mL of Normal Saline (0.9% NaCl) with 1mL of cardiac epinephrine (1:10,000 or 100mcg/mL). Administer to acutely correct a blood pressure indicative of shock (systolic <90). Administer a lower-end dose (0.5 – 1mL) while preparing a longer-term IVF drip (below).

- Concentration: 10mcg epinephrine/mL
- Onset: 1 minute
- Duration: 5 – 10 minutes
- Dose: 0.5 – 2mL every 2 – 5 minutes (5 – 20mcg)
- Administration: very slow IV push. 1 cc/min for 10 minutes. Rapid administration can cause rebound tachycardia, hypertensive emergency, and cardiac arrest.

Epinephrine as a vasopressor drip: Epinephrine; 4mcg/min bag reference chart. This dose is a starting/maintenance point in the application of an epinephrine (vasopressor) IV drip bag – Epinephrine Challenge. Gold-standard hospital practice utilizes a central line for this intervention; however, in an austere setting, peripheral antecubital access is acceptable (humeral, tibial, and sternal IO are also acceptable if flow rate can be precisely managed). The drip rate should be adjusted up, down or discontinued depending on the perfusion or vitals status of the patient. Once a vasopressor is started, the patient must be constantly monitored. Whenever possible, telemedicine consultation is required when vasopressor support is initiated.

Epinephrine 1:10,000 (Adrenaline) or Norepinephrine (Levophed) Drip Table

0.9% NaCl IVF Bag Size	Add to bag: EPI (or NOREPI): 1:10,000 (0.1 mg or 100mcg)/mL	Starting Dose (mcg/min)	DRIP SET:10gtts (Drops/mL) DRIP RATE: (Drops/min or gtts/min)	DRIP SET: 15gtts (Drops/mL) DRIP RATE: (Drops/min or gtts/min)
50mL	1mL (100mcg)	4 mcg/min	20 drops/min	30 drops/min
100mL	2mL (200mcg)	4 mcg/min	20 drops/min	30 drops/min
250mL	5mL (500mcg)	4 mcg/min	20 drops/min	30 drops/min
500mL	10mL (1mg)	4 mcg/min	20 drops/min	30 drops/min
1000mL (1L)	20mL (2mg)**	4 mcg/min	20 drops/min	30 drops/min

***This is the least recommended approach as it commits a high volume of epinephrine to a large bag. If the patient's vital signs (BP/MAP/HR) stabilize, the bag must be discontinued and the medic risks wasting some of his or her resources – "you can mix a drug in an IV bag, but you can't take it out."*

Key point: If administering epinephrine infusion via a peripheral IV, monitor the IV site with every vital signs check for signs of redness, swelling or induration (firm, chord-like feeling of vessel above IV site). If any of these are present, epinephrine may be leaking out of the IV ("extravasating") which can cause permanent scarring and damage to the vessel. Stop the infusion immediately and seek telemedicine consultation.

WARNING

Vasopressors are extremely potent medications. Besides the risk associated with peripheral infusions, dosing must be strictly monitored, and care must be taken to ensure proper dose is being consistently delivered. Providers should expect to see increases in both heart rate and blood pressure, but extreme tachycardia (as a sign of malignant cardiac rhythms) should prompt stopping the infusion and consulting telemedicine advice. Careful medical history should be obtained and patients with hypertension and/or coronary artery disease should only be administered these medications under strict guidance.

Use IV hydrocortisone, 100 mg every 8 hours, for at least 3 days in a military-aged male to treat septic shock in patients if adequate fluid resuscitation and vasopressor therapy are not able to restore hemodynamic stability. Due to the low volume and quality of evidence with this intervention, telemedicine is required before IV hydrocortisone is initiated as a treatment.[3]

APPENDIX G: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

U.S. ARMY AEROMEDICAL EVACUATION

STANDARD MEDICAL OPERATING GUIDELINES (SMOG)

CY23 Version

Published

January 2023

Effective 1 FEB 2023

Summary of Changes Located at End of Document

INTRODUCTION

The CY 2023 SMOG release marks the last year of the current format. The Aeromedical Evacuation community provided developmental feedback leading to a redesign of current written medical guidance and/or policy. Be assured all future changes are a continued result of collaboration between Emergency Medicine professionals, experienced Flight Medics, Aeromedical Physician Assistants, Critical Care Nurses, and Flight Surgeons across the Army. There is close coordination in the development of these guidelines with the Joint Trauma System, and the Defense Committees on Trauma. Our shared goal is to ensure the highest quality enroute care possible and to standardize care across all evacuation and emergency medical pre-hospital units. It is our vision that all these enhancements and improvements will advance enroute care across the services and the Department of Defense.

Unit Medical Trainers, Medical Standardization Instructors, Medical Flight Instructors and Medical Directors will evaluate Critical Care Flight Paramedics (CCFP) ability to follow and execute the medical instructions herein. These medical guidelines are intended to guide CCFPs and prehospital professionals in the response and management of emergencies and the care and treatment of patients in both garrison and combat theater environments. Unit medical providers are not expected to employ these guidelines blindly. Unit medical providers are expected to manipulate and adjust these guidelines to their unit's mission and medical air crew training / experience. Medical directors or designated supervising physicians will endorse these guidelines as a baseline, appropriately adjust components as needed, and responsibly manage individual unit medical missions within the scope of practice of their Critical Care Flight Paramedics, Enroute Critical Care Nurses, and advanced practice aeromedical providers.

CCFPs should administer medications as listed in the guidelines unless their medical director and/or supervising physician orders a deviation. Other medications may be added, so long as the unit supervising physician and/or medical director approves them.

This manual also serves as a reference for physicians providing medical direction and clinical oversight to the CCFP. Treatment direction, which is more appropriate to the patient's condition than the guideline, should be provided by the physician so long as the CCFP scope of practice is not exceeded.

Any medical guideline that is out of date or has been found to cause further harm will be updated or deleted immediately. The Department of Aviation Medicine (DAM) serves as the managing editor of the SMOG and is responsible for content updates, managing the formal review process, and identifying review committee members for the annual review.

The Standard Medical Operating Guidelines are intended to provide medical procedural guidance and is in compliment to other Department of Defense and Department of the Army policies, regulatory and doctrinal guidance. Nothing herein overrides or supersedes laws, rules, regulation or policies of the United States, DoD or DA.

Also available, along with all fillable evacuation forms and AARs on the Joint Trauma System website:
https://jts.amedd.army.mil/index.cfm/PI_CPGs/cpgs

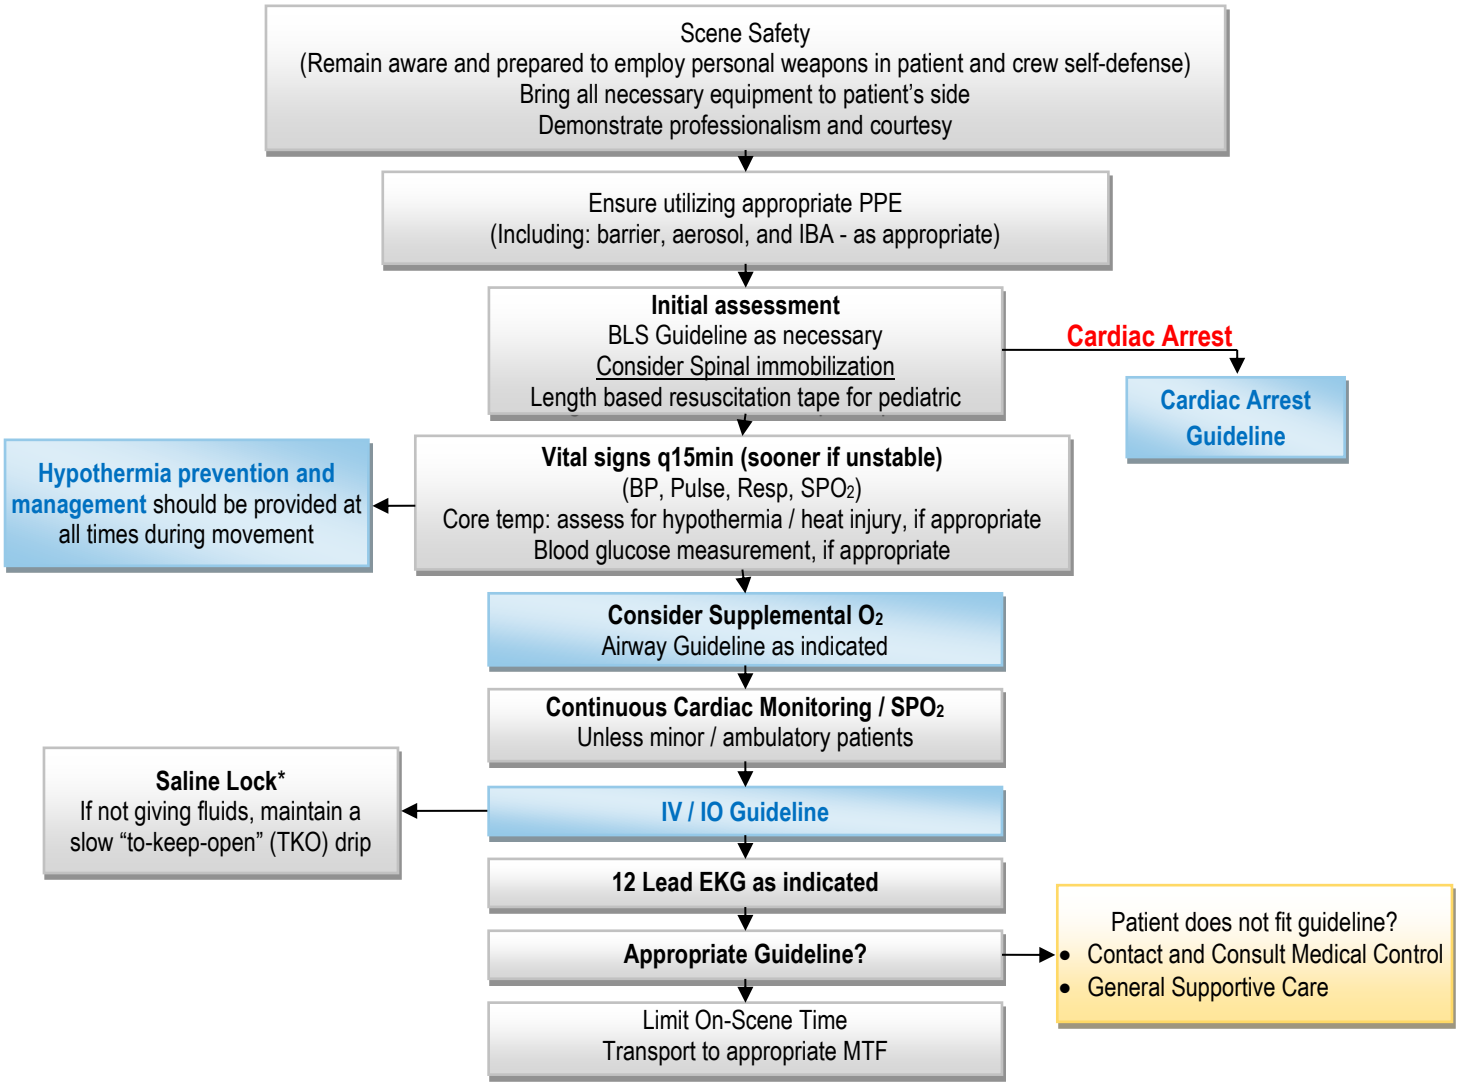
https://jts.amedd.army.mil/index.cfm/documents/forms_after_action

All comments and/or recommendations should be sent to:

medcoesaamoperations@army.mil

with the subject line "CCFP-SMOG"

UNIVERSAL PATIENT CARE

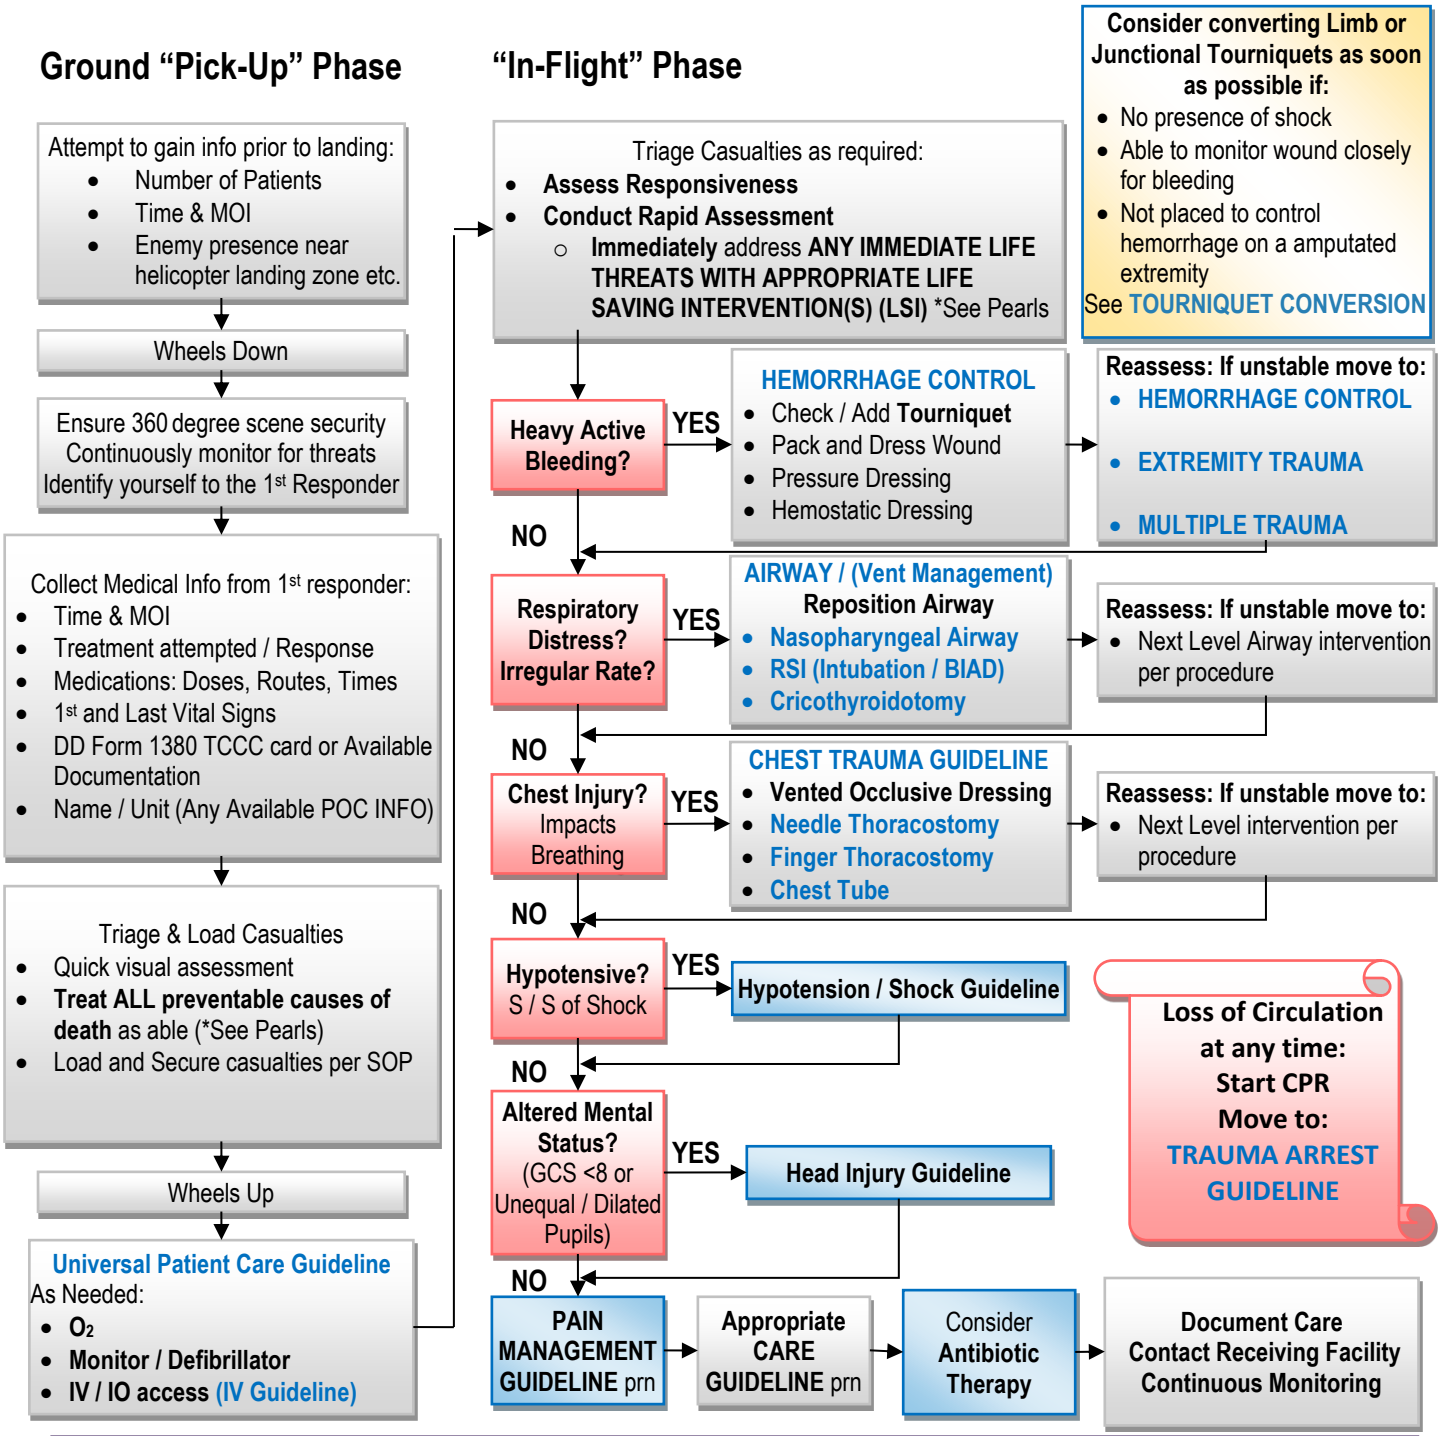


Scene Safety
(Remain aware and prepared to employ personal weapons in patient and crew self-defense)
Bring all necessary equipment to patient's side
Demonstrate professionalism and courtesy
Ensure utilizing appropriate PPE
(Including: barrier, aerosol, and IBA - as appropriate)
Initial assessment
BLS Guideline as necessary
Consider Spinal immobilization
Length based resuscitation tape for pediatric
Cardiac Arrest
Cardiac Arrest Guideline
Hypothermia prevention and management should be provided at all times during movement
Vital signs q15min (sooner if unstable)
(BP, Pulse, Resp, SPO2)
Core temp: assess for hypothermia / heat injury, if appropriate
Blood glucose measurement, if appropriate
Consider Supplemental O2
Airway Guideline as indicated
Continuous Cardiac Monitoring / SPO2
Unless minor / ambulatory patients
Saline Lock*
If not giving fluids, maintain a slow "to-keep-open" (TKO) drip
IV / IO Guideline
12 Lead EKG as indicated
Appropriate Guideline?
Patient does not fit guideline?
Contact and Consult Medical Control
General Supportive Care
Limit On-Scene Time
Transport to appropriate MTF

Pearls:

- *Blood/Fluid boluses given in trauma victims should be done in accordance with hypotensive resuscitation guidelines – see multiple trauma protocol.
- General supportive measures include: Airway / Respiratory support, continuous hemodynamic monitoring with SPO_2 and $EtCO_2$ as appropriate, Supplemental O_2 PRN, IV Fluid boluses, Pain control PRN.
- All patients should have complete vital signs recorded.
- All patient encounters should be recorded on appropriate care documentation sheets per theater policies, unit SOPs and/or in accordance with JTS Documentation CPG at end of a patient encounter.
- Any mishaps / errors should be brought to attention of the medical control ASAP.
- Contact medical control for any necessary assistance when feasible.

TACTICAL EVACUATION



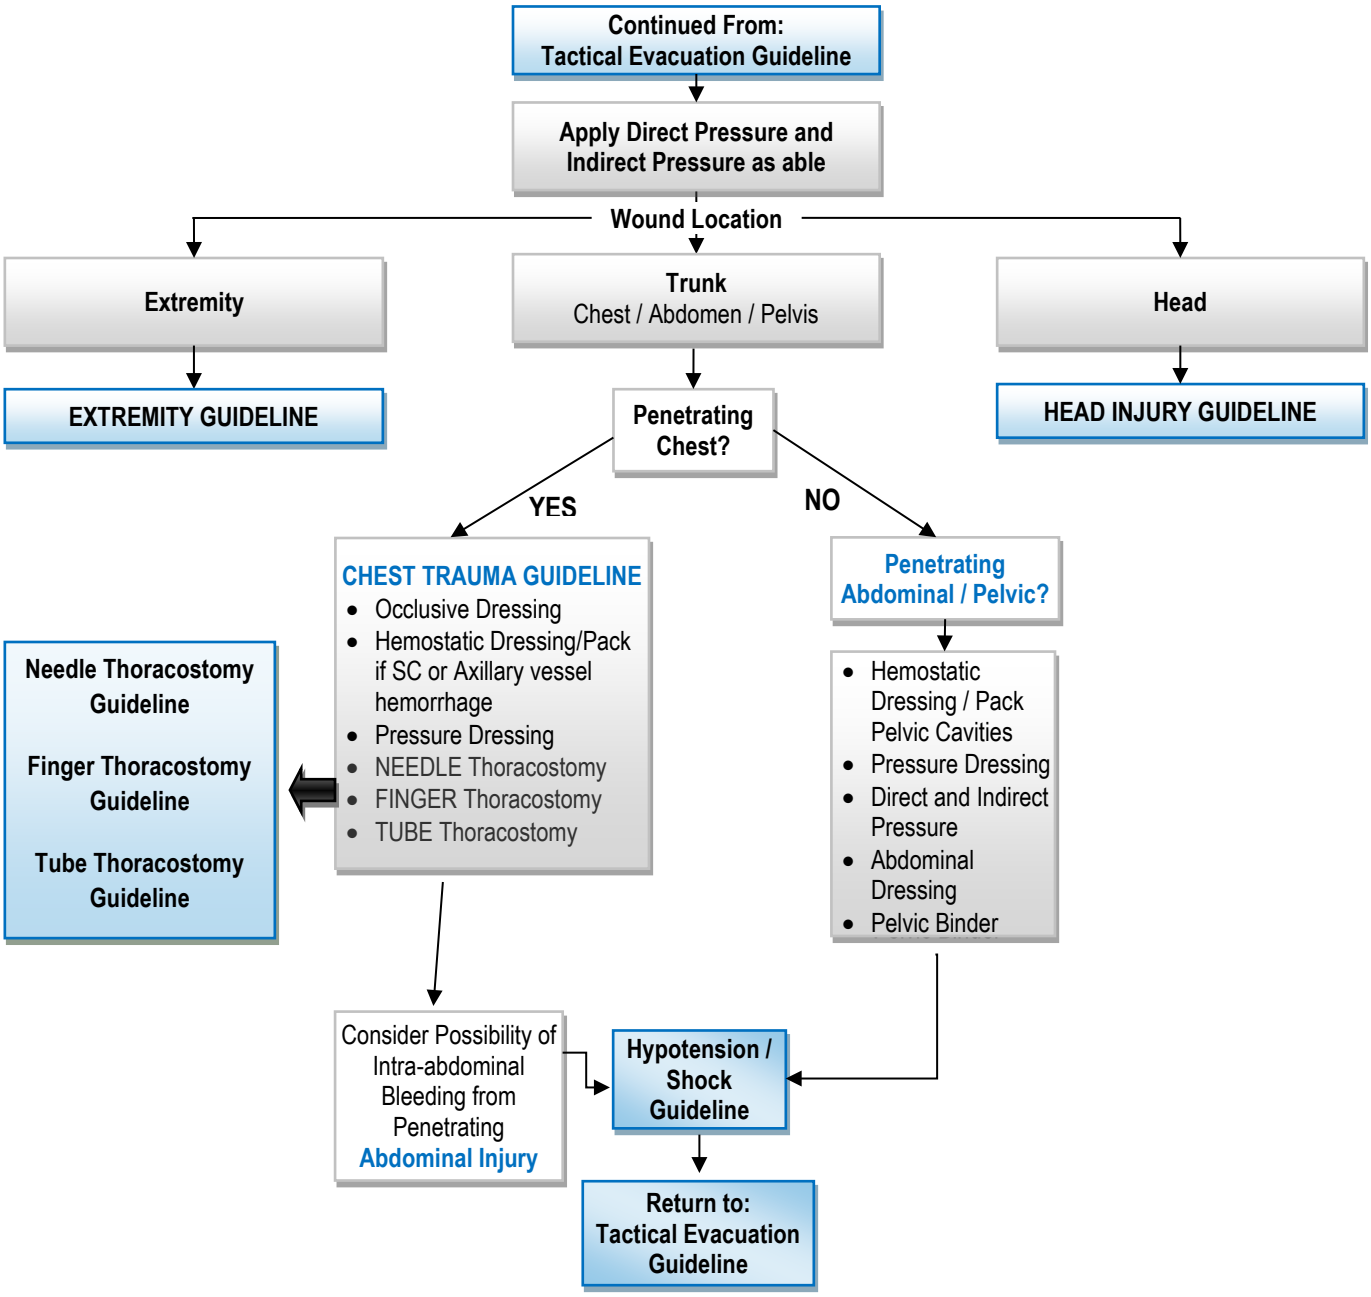
Pearls:

- ***If the tactical situation permits, all known preventable causes of death should be addressed prior to casualty transfer to an air ambulance (e.g., accessible sources of major hemorrhage, tension pneumothorax, and airway obstruction).**
- **Replace any limb tourniquets placed over the uniform (Hasty Tourniquet) with one applied directly to the skin (Deliberate), 2-3 inches above wound.**
- Goal < 5 minutes time on scene prior to wheels up.

HEMORRHAGE

Signs and Symptoms in a Trauma Patient

- **Obvious Arterial Bleeding**
- **Blood Pooling / Soaked Bandages**
- **Venous Bleeding from Extensive Penetrating Wounds** (Multiple fragments)
- **Tachycardia**
- **Distended / Tender Abdomen**
- **Shortness of Breath / Difficulty Breathing / Tachypnea**
- **Decreased LOC**
- **Signs / Symptoms Shock**
- **Hypotension**

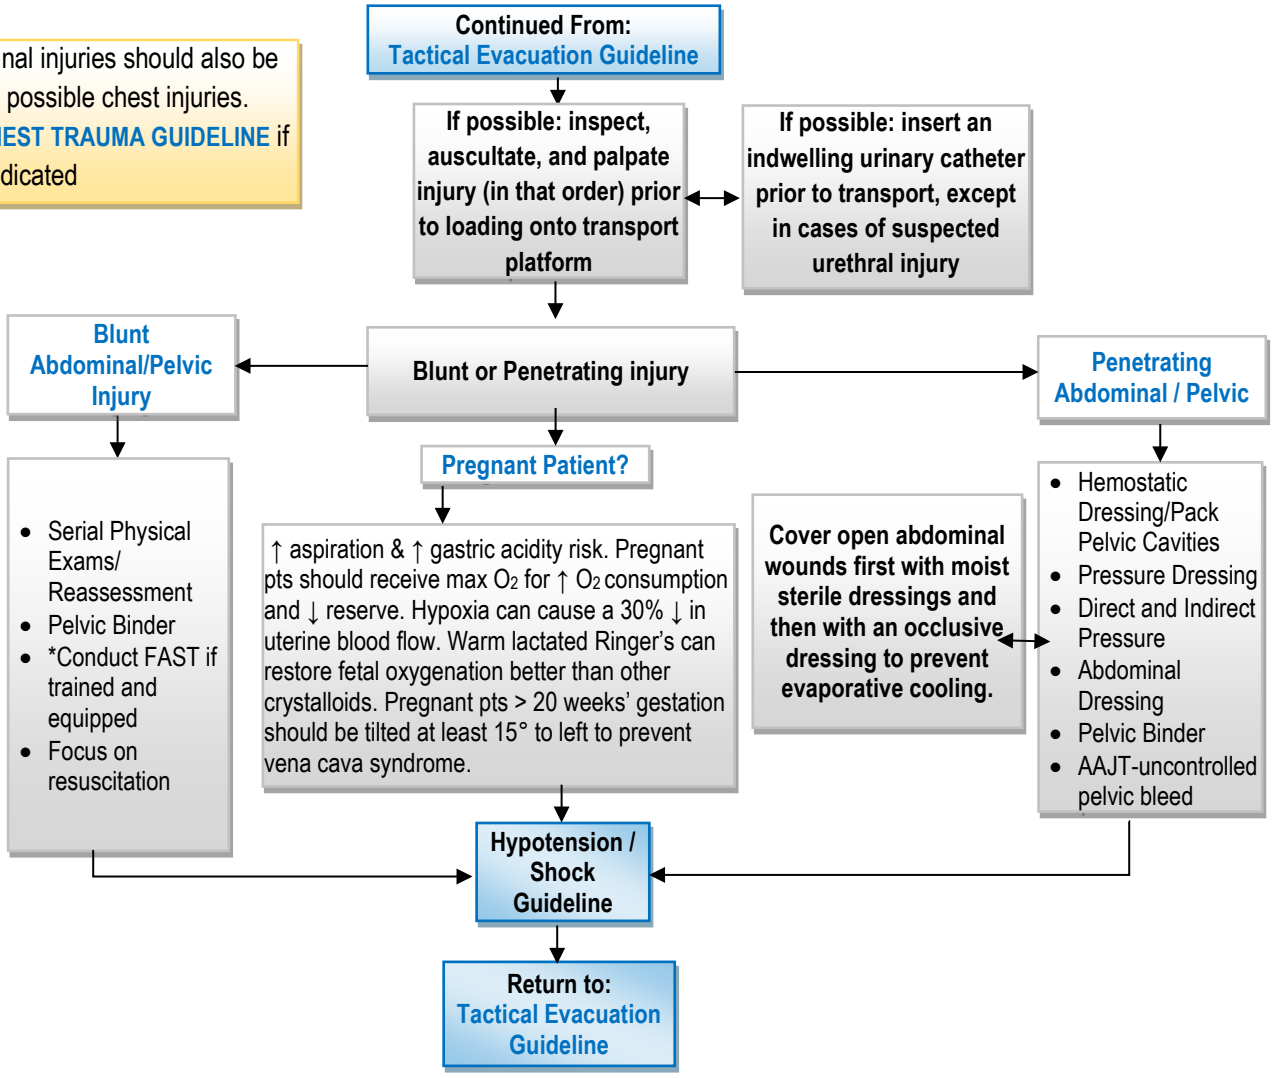


ABDOMINAL INJURY

Signs and Symptoms

- **Altered mental status**
- **Tachycardia**
- **Absence of palpable pulses**
- **Pale, moist, and mottled skin**
- **Poor peripheral perfusion**
- **Hypotension**
- **Hematuria**
- **Pain, Tenderness, Distention, Dissymmetry**
- **Absent/Diminished bowel sounds**
- **Grey Turner Sign**
- **Cullen Sign**
- **Kehr's Sign**

All Abdominal injuries should also be considered possible chest injuries. Consult **CHEST TRAUMA GUIDELINE** if S/Sx are indicated



Continued From:
Tactical Evacuation Guideline
If possible: inspect, auscultate, and palpate injury (in that order) prior to loading onto transport platform
If possible: insert an indwelling urinary catheter prior to transport, except in cases of suspected urethral injury
Blunt or Penetrating injury
Blunt Abdominal/Pelvic Injury
Penetrating Abdominal / Pelvic
Pregnant Patient?
Serial Physical Exams/ Reassessment
Pelvic Binder
*Conduct FAST if trained and equipped
Focus on resuscitation
↑ aspiration & ↑ gastric acidity risk. Pregnant pts should receive max O2 for ↑ O2 consumption and ↓ reserve. Hypoxia can cause a 30% ↓ in uterine blood flow. Warm lactated Ringer's can restore fetal oxygenation better than other crystalloids. Pregnant pts > 20 weeks' gestation should be tilted at least 15° to left to prevent vena cava syndrome.
Cover open abdominal wounds first with moist sterile dressings and then with an occlusive dressing to prevent evaporative cooling.
Hemostatic Dressing/Pack Pelvic Cavities
Pressure Dressing
Direct and Indirect Pressure
Abdominal Dressing
Pelvic Binder
AAJT-uncontrolled pelvic bleed
Hypotension / Shock Guideline
Return to:
Tactical Evacuation Guideline

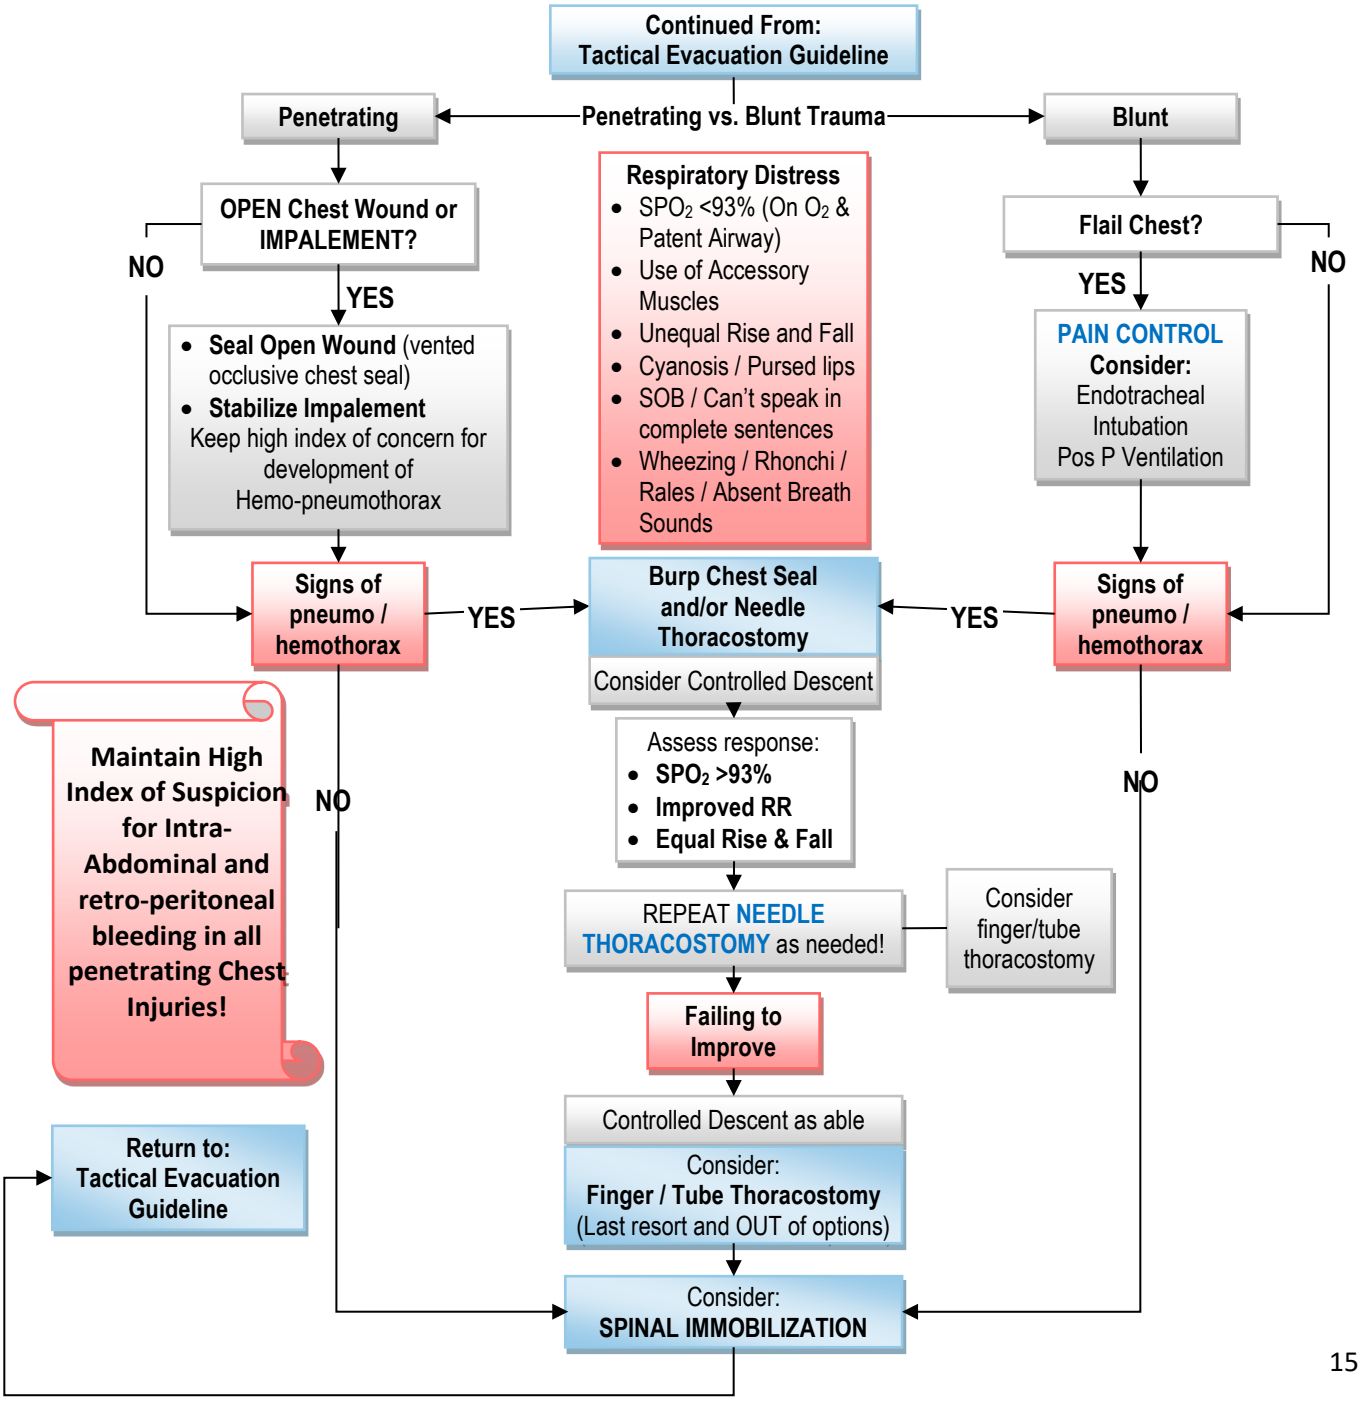
Pearls:

- *FAST Cannot reliably exclude clinically significant injuries, but may provide reasonable indications of intra-abdominal hemorrhage which requires surgical intervention
- **Pain management should not be withheld.
- Lateral contusions (seatbelt sign) associated with a 20% occurrence of internal injury and should alert the CCFP to possible internal injury
- Presence of pregnant uterus should be determined. Traumatic injuries to pregnant patients is further complicated by physiological changes experienced by the patient. Some changes can mimic shock (heart rate can increase by 20 BPM, blood volume increases by 50% during mid-pregnancy, and can experience relative anemia from hemodilution.) Due to the increase in blood flow to the uterus, risk of massive blood loss is greatly increased with trauma to the bony pelvis. At term, the placenta/uterus can perfuse approximately 600-800 mL of blood per minute.

CHEST TRAUMA

Signs and Symptoms of Chest Trauma

- **Difficulty Breathing:** Cyanosis / Pursing of lips / Accessory muscle involvement
- **Rapid Respirations with SPO_2 decreasing or <93%** (Trauma: In Flight and on O_2)
- **Flail Chest**
- **Unequal Rise and Fall**
- **Open Wound / Impalement Over Thorax**
- **Penetrating Abdominal Wound**
- **Bruising Across Chest or Base of Neck**
- **Subcutaneous Emphysema or Deviated Trachea**



EXTREMITY TRAUMA

Signs and Symptoms:
- **Pain / Swelling**
- **Deformity**
- **Altered Sensation / Function**
- **Diminished Pulse / Cap Refill**
- **Decreased Temperature**
- **Bleeding**

Differential Diagnosis:
- **Abrasion**
- **Contusion**
- **Multi-trauma**
- **Fracture**
- **Dislocation**
- **Laceration**
- **Sprain / Strain**
- **Amputation**

Continued From: Tactical Evacuation Guideline

Multiple Injury Sites — YES → **Multiple Trauma Guideline**

NO

Heavy Active Bleeding? — YES →

HEMORRHAGE CONTROL
- Check / Add **Tourniquet (Add DELIBERATE tourniquet if HASTY tourniquets only in place)**
- Pack and Dress Wound
- Pressure Dressing
- Hemostatic Dressing

NO

IV / IO Guideline

Pain Control Guideline

Wound Care / Protection
- Bandage and Cover Injuries
- Immobilize Extremity
- Ice (if available) for Edema

Fluid Resuscitation
- Whole Blood (if available)
- pRBCs and plasma (if available)
- Platelets (If authorized)
- Crystalloid (LR/NS)
- PlasmaLyte A

After Bleeding Controlled:
If Hypotensive or showing signs / symptoms of hypotension or shock
Move immediately to:
HYPOTENSION / SHOCK Guideline

Was it Amputated?

- Clean amputated part
- Wrap in sterile dressing damp with Normal Saline
- Place in plastic bag / air tight container
- Place limb in sealed container in ice bath slurry if available
- Transport with Patient
- Pelvic Binder for Explosive Mechanisms

Consider converting Limb or Junctional Tourniquets as soon as possible if:
- No presence of shock
- Able to monitor wound closely for bleeding
- Not placed to control hemorrhage on a amputated extremity

See TOURNIQUET CONVERSION

Pearls:
- Evaluate and document neurovascular status in all fractures / dislocations.
- Never attempt to reduce an open fracture unless you have a confirmed loss of pulse.
- Blood loss can be severe and concealed in long bone fractures – especially the femur.
- Tourniquets should be used without hesitation to control major bleeding. Use only CoTCCC Approved Tourniquets!
- Limb and junctional tourniquets should be converted to hemostatic or pressure dressings as soon as possible if three criteria are met: the casualty is not in shock; it is possible to monitor the wound closely for bleeding; and the tourniquet is not being used to control bleeding from an amputated extremity. Every effort should be made to convert tourniquets in less than 2 hours if bleeding can be controlled with other means.

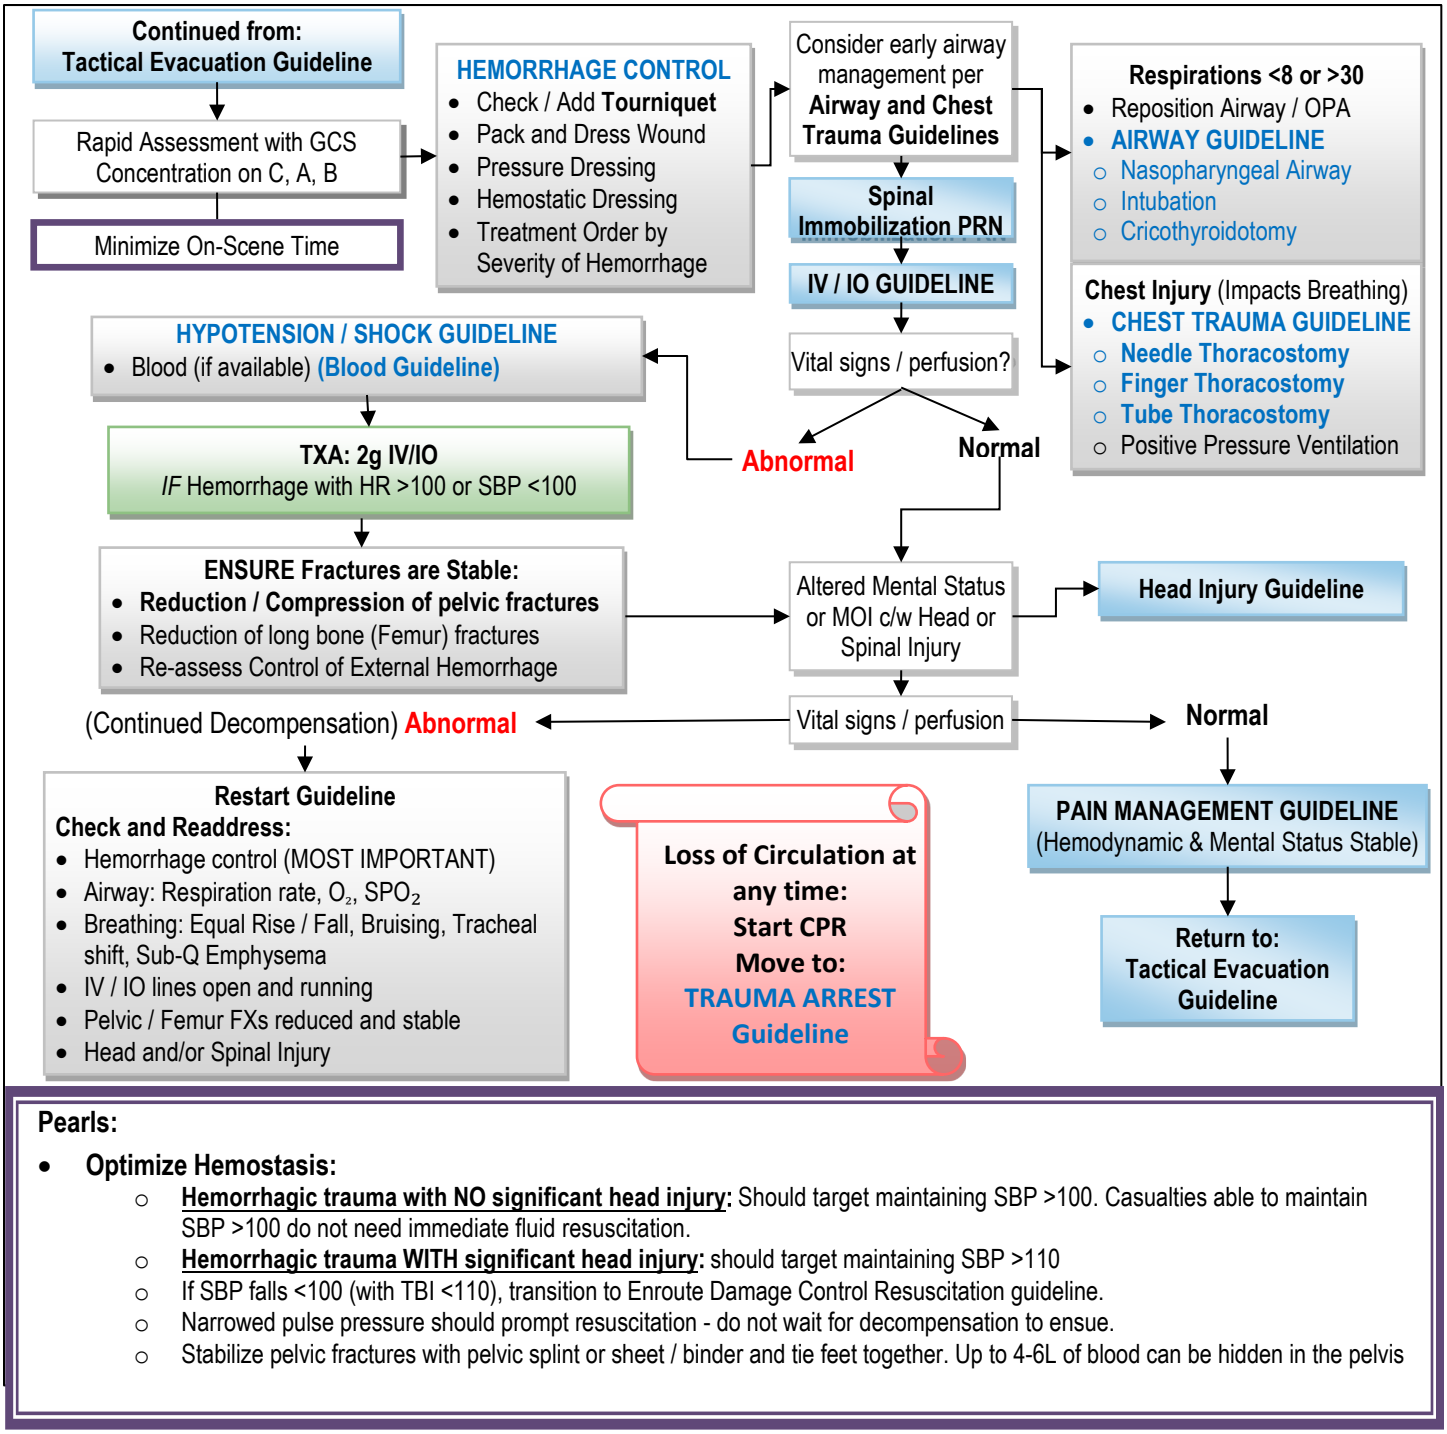
MULTIPLE TRAUMA

Signs and Symptoms:

- **Pain, Swelling, Bleeding, Ecchymosis**
- **Deformity**
- **Altered Mental Status**
- **Respiratory Distress / Failure**
- **Vomiting**
- **Hypotension / Shock**
- **Cardiac Arrest**

Possible Injuries / Diagnoses:

- **Tension Pneumothorax**
- **Flail Chest**
- **Pericardial Tamponade**
- **Open Chest Wound**
- **Hemothorax**
- **Intra-abdominal Injury / Bleeding**
- **Head Injury, HEENT injuries**
- **Extremity Fracture / Dislocation**
- **Hypothermia**
- **Burns**
- **Pelvis / Long-bone Fracture**
- **Spine / Spinal Cord Injury**



Continued from: Tactical Evacuation Guideline
Rapid Assessment with GCS Concentration on C, A, B
Minimize On-Scene Time
HEMORRHAGE CONTROL
Check / Add Tourniquet
Pack and Dress Wound
Pressure Dressing
Hemostatic Dressing
Treatment Order by Severity of Hemorrhage
Consider early airway management per Airway and Chest Trauma Guidelines
Spinal Immobilization PRN
IV / IO GUIDELINE
Vital signs / perfusion?
Abnormal
Normal
Respirations <8 or >30
Reposition Airway / OPA

Nasopharyngeal Airway
Intubation
Cricothyroidotomy
Chest Injury (Impacts Breathing)
CHEST TRAUMA GUIDELINE
Needle Thoracostomy
Finger Thoracostomy
Tube Thoracostomy
Positive Pressure Ventilation
HYPOTENSION / SHOCK GUIDELINE
Blood (if available) (Blood Guideline)
TXA: 2g IV/IO
IF Hemorrhage with HR >100 or SBP <100
ENSURE Fractures are Stable:
Reduction / Compression of pelvic fractures
Reduction of long bone (Femur) fractures
Re-assess Control of External Hemorrhage
Altered Mental Status or MOI c/w Head or Spinal Injury
Head Injury Guideline
Vital signs / perfusion
(Continued Decompensation) Abnormal
Normal
Restart Guideline
Check and Readdress:
Hemorrhage control (MOST IMPORTANT)
Airway: Respiration rate, O2, SPO2
Breathing: Equal Rise / Fall, Bruising, Tracheal shift, Sub-Q Emphysema
IV / IO lines open and running
Pelvic / Femur FXs reduced and stable
Head and/or Spinal Injury
Loss of Circulation at any time:
Start CPR
Move to:
TRAUMA ARREST Guideline
PAIN MANAGEMENT GUIDELINE
(Hemodynamic & Mental Status Stable)
Return to: Tactical Evacuation Guideline

Pearls:

- **Optimize Hemostasis:**
  - **Hemorrhagic trauma with NO significant head injury:** Should target maintaining SBP >100. Casualties able to maintain SBP >100 do not need immediate fluid resuscitation.
  - **Hemorrhagic trauma WITH significant head injury:** should target maintaining SBP >110
  - If SBP falls <100 (with TBI <110), transition to Enroute Damage Control Resuscitation guideline.
  - Narrowed pulse pressure should prompt resuscitation - do not wait for decompensation to ensue.
  - Stabilize pelvic fractures with pelvic splint or sheet / binder and tie feet together. Up to 4-6L of blood can be hidden in the pelvis

Pediatric MULTIPLE TRAUMA

Signs and Symptoms:

- **Pain, Swelling, Bleeding**
- **Ecchymosis**
- **Deformity**
- **Altered Mental Status**
- **Respiratory Distress / Failure**
- **Vomiting**
- **Hypotension / Shock**
- **Cardiac Arrest**

Possible Injuries / Diagnoses:

- **Tension Pneumothorax**
- **Flail Chest**
- **Pericardial Tamponade**
- **Open Chest Wound**
- **Hemothorax**

  - Positive Pressure Ventilation

TXA if: Hemorrhage with ↑HR or ↓SBP Average

Pediatric HYPOTENSION / SHOCK GUIDELINE

- WB, 1:1:1, or pRBC's (if available) (**Blood Guideline**)
- Bolus **ALL FLUIDS**
- 10mL/kg Blood Bolus in <20 min.
- 20mL/kg IVF if blood not available

ENSURE Fractures are Stable:

- **Reduction / Compression of pelvic fractures**
- Reduction of long bone (Femur) fractures
- Reassess Control of External Hemorrhage

Altered Mental Status or MOI c/w Head or Spinal Injury

Head Injury Guideline

Vital Signs / Perfusion?

(Continued Decompensation) **Abnormal**

Normal

Restart Guideline

Check and Readdress:

- Hemorrhage control
- Airway: Respiration rate, O_2, and Sats
- Breathing: Equal Rise / Fall, Bruising, Tracheal shift, Sub-Q Emphysema
- IV / IO lines open and running
- Pelvic / Femur FXs reduced and stable
- Head and/or Spinal Injury

Loss of Circulation at any time: **Start CPR**
100-120 Comp/Min

- 1 Rescuer: 30 Compressions to 2 Breaths
- 2 Rescuer: 15 Compressions to 2 Breaths

Move to: **TRAUMA ARREST Guideline**

Pediatric PAIN MANAGEMENT GUIDELINE
(Hemodynamic & Mental Status Stable)

Return to: Tactical Evacuation Guideline

Pearls:

- **Resuscitation: Maintain, SBP to at least [70 + 2 x age (yr)] or to mental status change.**
- **Normotesion: [90 + 2 x age (yr)]**
- Narrowed pulse pressure should prompt resuscitation – do not wait for decompensation to ensue.
- Stabilize pelvic fractures with Pelvic Splint or sheet / binder and tie feet together. Up to 80% of blood volume can be hidden in the pelvis.
- Follow Length Based Resuscitation Tape for Pediatric ALS Equipment.

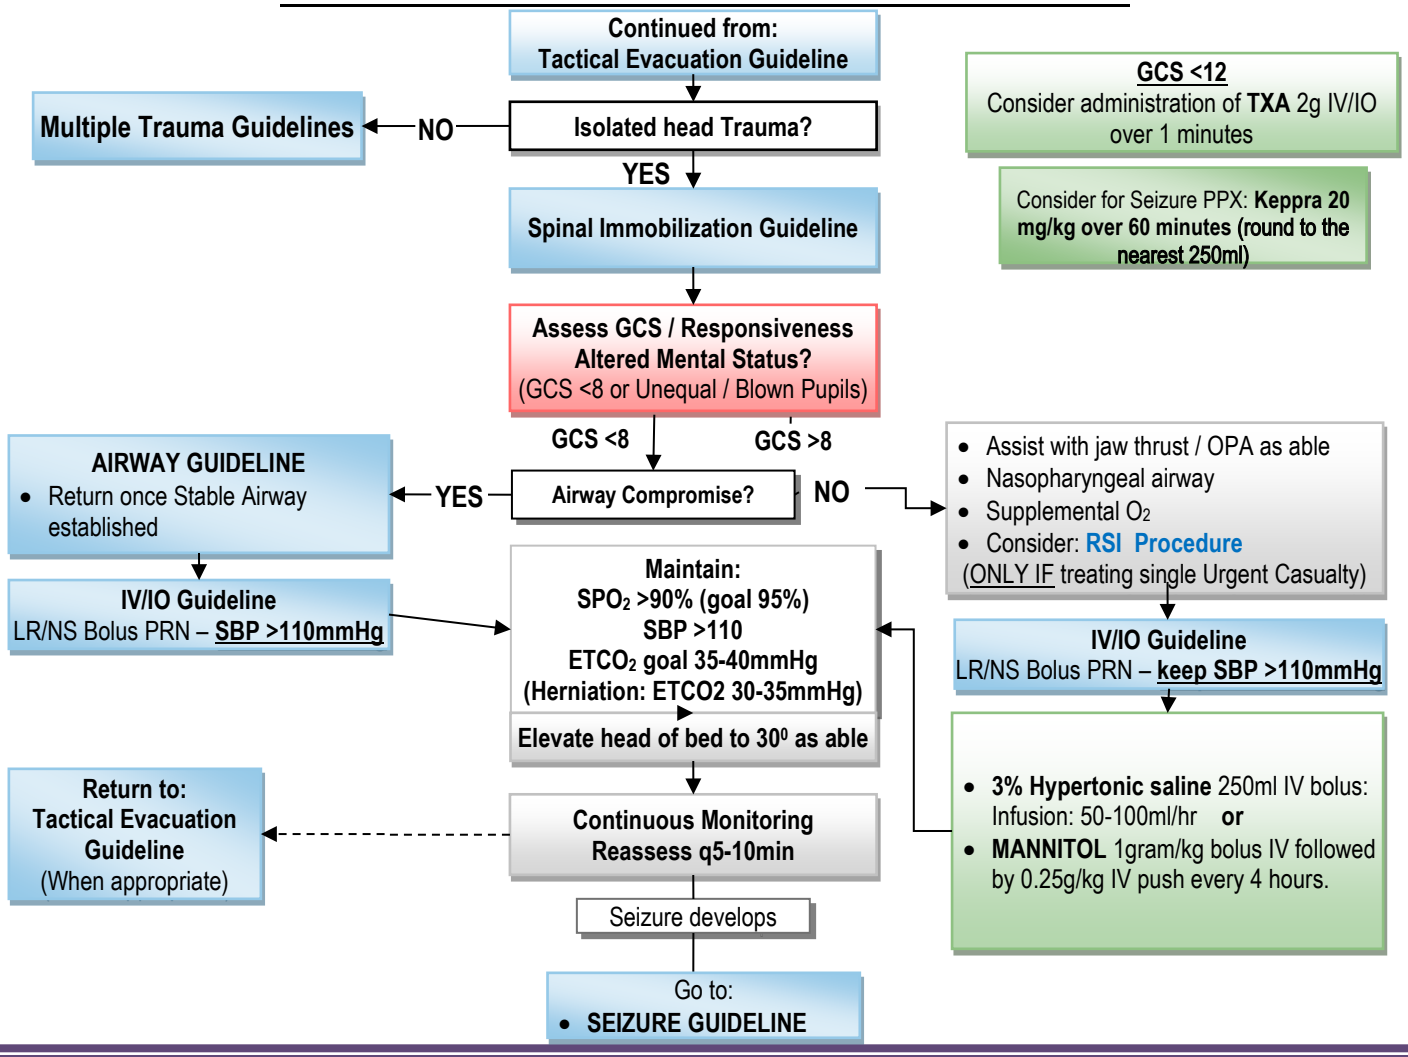
HEAD INJURY/TBI

Signs and Symptoms:

- **Pain, Swelling, Bleeding**
- **Ecchymosis**
- **Deformity**
- **Altered Mental Status**
- **Respiratory Distress / Failure**
- **Vomiting**

Differential Diagnosis:

- **Skull Fracture**
- **Brain Injury**
- **Epidural Hematoma**
- **Subdural Hematoma**
- **Subarachnoid Hemorrhage**
- **Spinal Injury**
- **Abuse**



Pearls:

Evidence of Elevated ICP and Herniation: Unilateral or Bilateral Fixed / Sluggish and blown pupils, persistent/repetitive vomiting, decorticate or decerebrate posture, motor abnormalities, Cushing's **Reflex**: (Hypertension & Bradycardia +/- Respiratory depression)

- Prevention of hypoxic insult is key! Maintain PO_2 and maintain cerebral perfusion pressure by preventing hypotension.
  - Target Vital Functions: **SBP >110mm Hg, SPO_2 >95%, $ETCO_2$ at 35-40mmHg, MAP 80-110.**
  - It is CRITICALLY IMPORTANT to avoid both hypo-capnea and hyper-capnea. Dedicated and closely managed ventilation is key to optimal patient outcome.
- With clear signs of **herniation,** may consider *temporizing* hyperventilation with 100% O_2 and capnography: **titrate CO_2 to 30-35mm Hg**.
- **Mannitol** should be given as boluses – not a constant infusion. Do not use in hypotensive, dehydration, or under-resuscitated patients
- **KETAMINE** Not an absolute contraindicated in ICP with hypertension and/or spontaneous cerebral hemorrhage.

BURNS

Signs and Symptoms:

- **Burns, Pain, Swelling**
- **Dizziness**
- **Loss of Consciousness**
- **Airway Involvement (e.g., singed nasal hair, carbonaceous sputum)**
- **Hoarseness / Wheezing**
- **Loss of Consciousness**

Differential Diagnosis:

- **Superficial Burns (1st degree)**
- **Partial Thickness (2nd degree)**
- **Full Thickness (3rd degree)**
- **Chemical Burns**
- **Thermal Burns**
- **Electrical Burns**
- **Radiation**
- **Secondary Trauma**

All TC3 interventions can be done through burnt or charred skin e.g. IV, TQ, surgical cricothyroidotomy, needle decompression. Consider escharotomy if circumferential burn to chest compromising ventilation.

>40% TBSA burn, comatose, symptomatic inhalation injury, or deep facial require large ETT (Sz 8 adult)

Universal Patient Care Guideline

↓

Remove rings, bracelets, or other constricting items

↓

Rapid exam for additional Injuries

↓

Position patient supine Immobilize area

↓

AIRWAY INVOLVEMENT?

YES → **AIRWAY Guideline** Consider: Early establishment of Advanced Airway

→ **Pediatric AIRWAY Guideline** Consider: Early establishment of Advanced Airway

→ Return to **AIRWAY INVOLVEMENT?**

NO →

THERMAL / ELECTRIC (See Pearl)

↓

Remove burning / charred clothing Cool with sterile saline / gel pad

↓

Cover with Dry sheet / dry sterile dressings

CHEMICAL (See Pearl)

↓

Brush off any dry chemical contamination

↓

Cut off contaminated clothing Flush area with saline 10-15min

↓

If Eye is involved: Flush with saline x 30min

↓

Determine / Start Fluid Replacement (BURN Fluid Resuscitation)

↓

HYPOTHERMIA PREVENTION

↓

PAIN CONTROL

↓

Place Foley Catheter (as able) Monitor Urinary Output

→ **Tactical Evacuation Guideline**

Burn Depth:

Superficial / Partial Thickness Burns:

- **1st Degree:** (limited to epidermis) Red, Hypersensitive, and Painful: Not medically significant and not calculated in Fluid Therapy
- **2nd Degree:** (epidermis and part of dermis) Very Painful, Red and Blistered, Wet, Weepy or Whiter and Edematous

Full Thickness Burns

- **3rd Degree:** (destruction throughout dermis) Non Painful, Whitish / Charred skin often with coagulate vessels (does not blanch to touch)
- **4th Degree:** (destruction through fat, fascia, muscle, and bone)

Pearl: Hydrofluoric Acid- Arterial infusion over 4 hr (40mL of D5W with 10mL of 10% calcium gluconate).
Tear Gas- rinse skin and eyes with NS.
Alkali Burns to eye- 1-2 L of NS each eye for 30 minutes.
All symptomatic electric burn patients require an ECG regardless of the potential voltage.

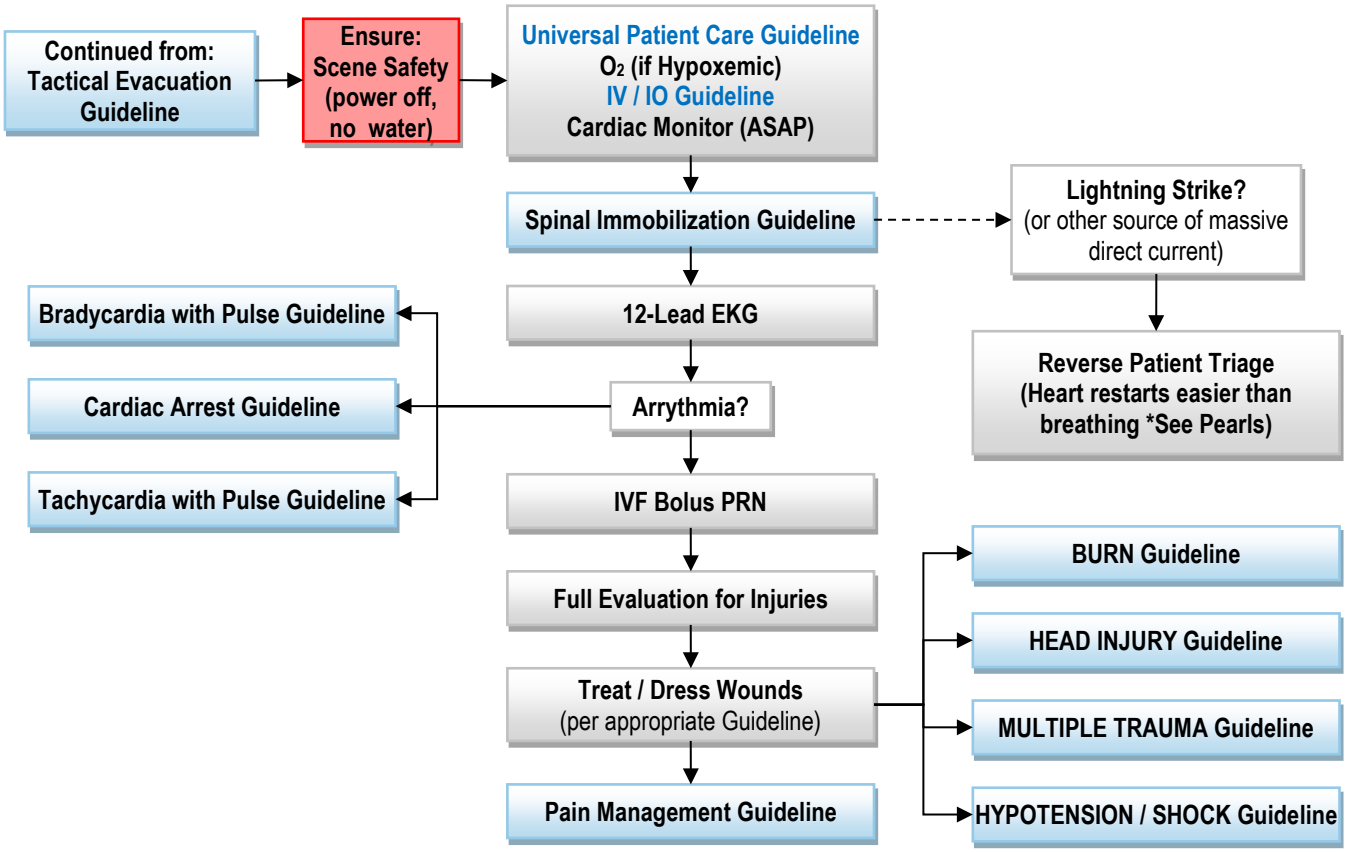
Urinary Output is the MOST Reliable Guide Predicting Adequate Resuscitation

- **Adult: 0.5ml per kg per hour (100mL/hr Electrical Burn)**
- **Children <40kg: 1ml/kg/hr**

ELECTRICAL INJURY

Signs and Symptoms:
- Burns
- Pain
- Arrhythmia
- Loss of Consciousness
- Entry / Exit Wounds
- Shock / Hypotension
- Cardiac Arrest

Differential Diagnosis:
- Cardiac Arrest
- Environmental Exposure
- Seizure
- Burns
- Multiple Trauma



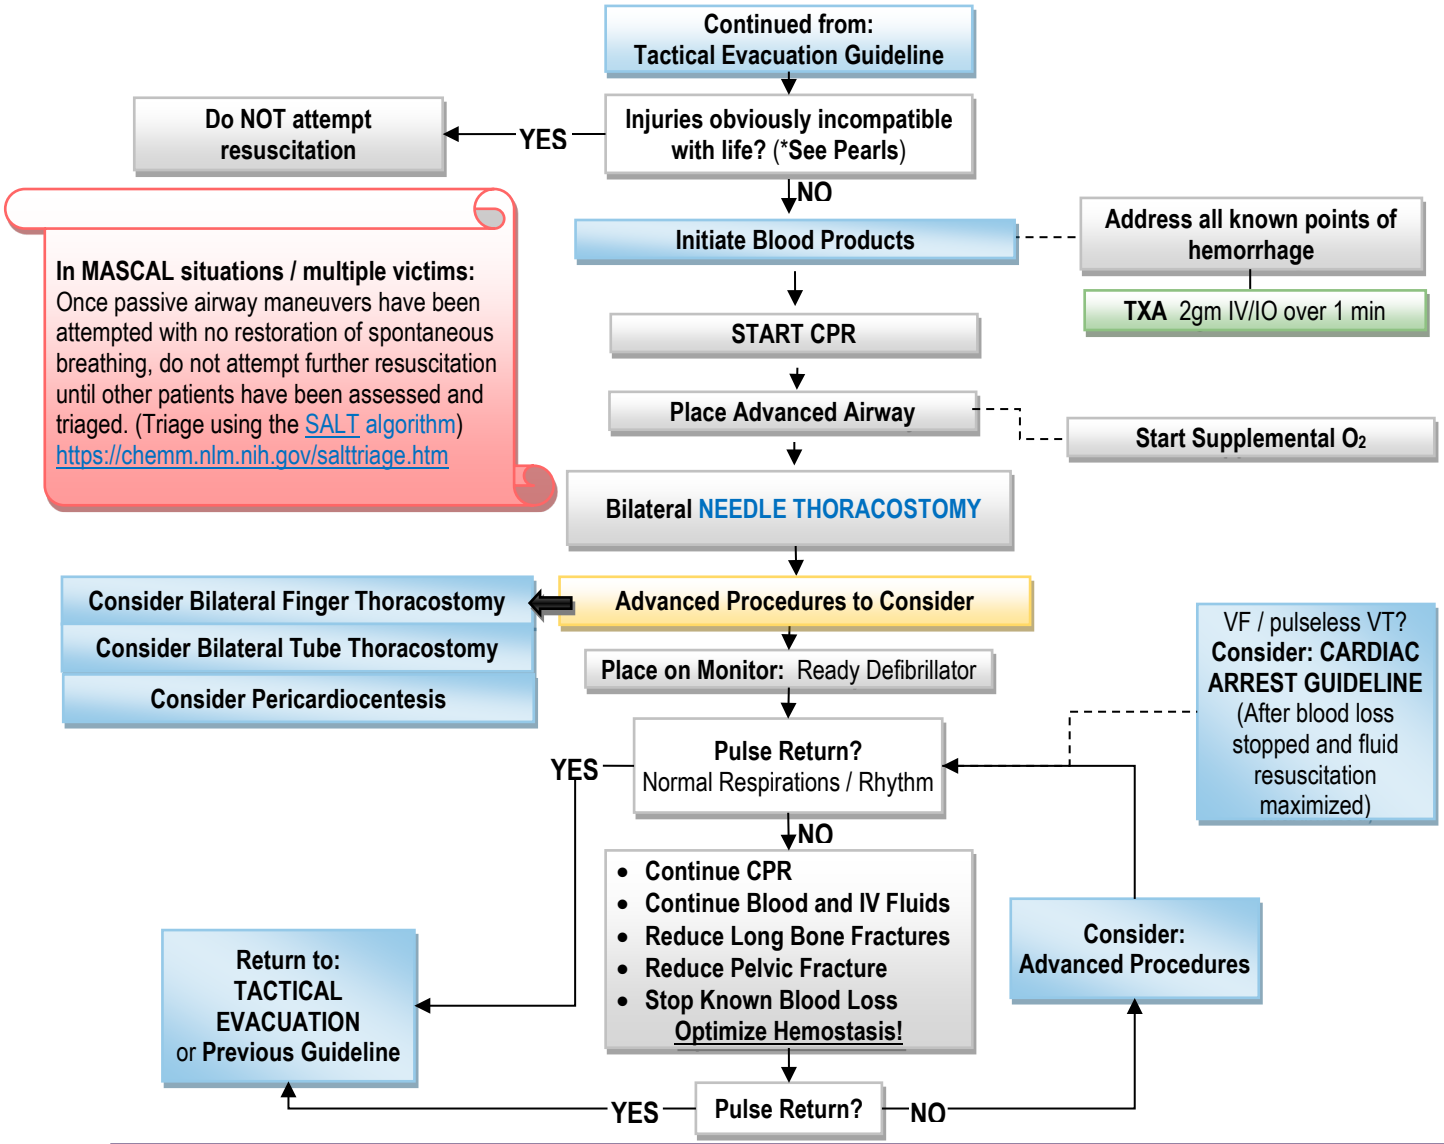
Continued from: Tactical Evacuation Guideline
Ensure: Scene Safety (power off, no water)
Universal Patient Care Guideline
O2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)
Spinal Immobilization Guideline
Lightning Strike? (or other source of massive direct current)
Reverse Patient Triage (Heart restarts easier than breathing *See Pearls)
12-Lead EKG
Bradycardia with Pulse Guideline
Cardiac Arrest Guideline
Tachycardia with Pulse Guideline
Arrythmia?
IVF Bolus PRN
Full Evaluation for Injuries
Treat / Dress Wounds (per appropriate Guideline)
Pain Management Guideline
BURN Guideline
HEAD INJURY Guideline
MULTIPLE TRAUMA Guideline
HYPOTENSION / SHOCK Guideline

Pearls:
- **Ventricular fibrillation (in AC) and asystole (in DC) are the most common dysrhythmias seen with electrical shock.**
- Damage is often hidden deep as current follows conductive structures (e.g., blood vessels, nerves, muscle).
- **In mass casualty situations where lightning is involved – reverse triage should be performed. <u>Those victims in full arrest should be resuscitated first.</u> The reason for this is the respiratory center of the brain takes longer to recover from the shock than the heart and respiratory support during this period can lead to survival.**
  - Specifically, if there are no spontaneous respirations after airway maneuver, but no other signs of non-survivable injury, administer ventilatory support aggressively as personnel resources allow.
- Do not overlook secondary trauma.
- Electrical shock victims do not "store" electricity and are safe to handle if current is off.
- Many electrical injury patients will also have significant burn injuries – do not overlook fluid resuscitation.

TRAUMATIC ARREST

Signs and Symptoms:
- **Evidence of Trauma with No Pulse**
- **Lack of Response to External Stimuli**

Differential Diagnosis:
- **Medical Cause of Arrest Preceding Trauma***
- **Tension Pneumothorax**
- **Hypovolemia**
- **Cardiac Tamponade**



Continued from: Tactical Evacuation Guideline
Injuries obviously incompatible with life? (*See Pearls)
YES
Do NOT attempt resuscitation
NO
Initiate Blood Products
Address all known points of hemorrhage
TXA 2gm IV/IO over 1 min
START CPR
Place Advanced Airway
Start Supplemental O2
Bilateral NEEDLE THORACOSTOMY
Advanced Procedures to Consider
Consider Bilateral Finger Thoracostomy
Consider Bilateral Tube Thoracostomy
Consider Pericardiocentesis
Place on Monitor: Ready Defibrillator
Pulse Return?
Normal Respirations / Rhythm
YES
NO
VF / pulseless VT?
Consider: CARDIAC ARREST GUIDELINE
(After blood loss stopped and fluid resuscitation maximized)
Continue CPR
Continue Blood and IV Fluids
Reduce Long Bone Fractures
Reduce Pelvic Fracture
Stop Known Blood Loss
Optimize Hemostasis!
Consider: Advanced Procedures
Return to: TACTICAL EVACUATION or Previous Guideline
Pulse Return?
YES
NO
In MASCAL situations / multiple victims:
Once passive airway maneuvers have been attempted with no restoration of spontaneous breathing, do not attempt further resuscitation until other patients have been assessed and triaged. (Triage using the SALT algorithm)
https://chemm.nlm.nih.gov/salttriage.htm

Pearls:
- **Injuries obviously incompatible with life** include decapitation, massively deforming head / chest injury, traumatic hemi-corpectomy or total body disruption, incineration, lividity/rigor mortis.
- If unsure if arrest due to trauma or medical cause, initiate ALS guideline for any arrhythmias following optimization of hemostasis (in trauma patients, volume loss must be corrected 1st, consider blood admin above all else)
- CPR without addressing massive hemorrhage, blood volume resuscitation, tension pneumothorax, and pericardial tamponade will be ineffective..
- *Consider severe hypocalcemia if blood products have recently been transfused due to calcium chelation and evidence of poor cardiac activity/contractility.

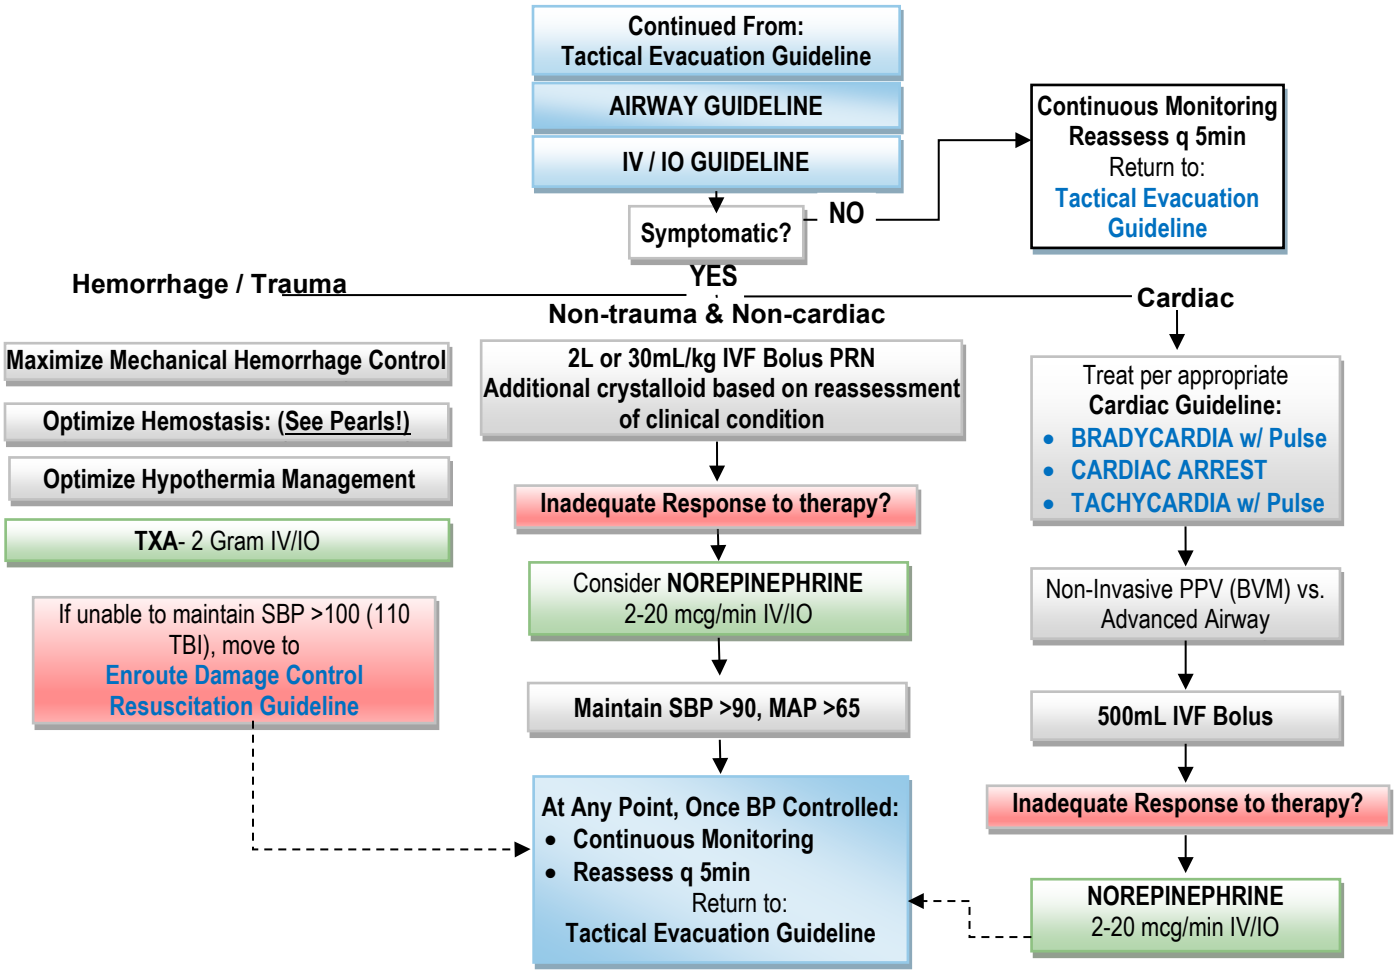
HYPOTENSION / SHOCK

Signs and Symptoms:

- Restlessness / Confusion
- Weakness / Dizziness
- Tachycardia
- Pale, Cool, Clammy Skin
- Delayed Capillary Refill
- Hypotension
- Bleeding
- Nausea / Vomiting

Differential Diagnosis:

- Shock: Hypovolemic, Cardiogenic, Septic, Neurogenic, Anaphylactic
- Cardiac Arrhythmia
- Pulmonary Embolus
- Tension Pneumothorax
- Medication Effect / OD
- Vasovagal Episode

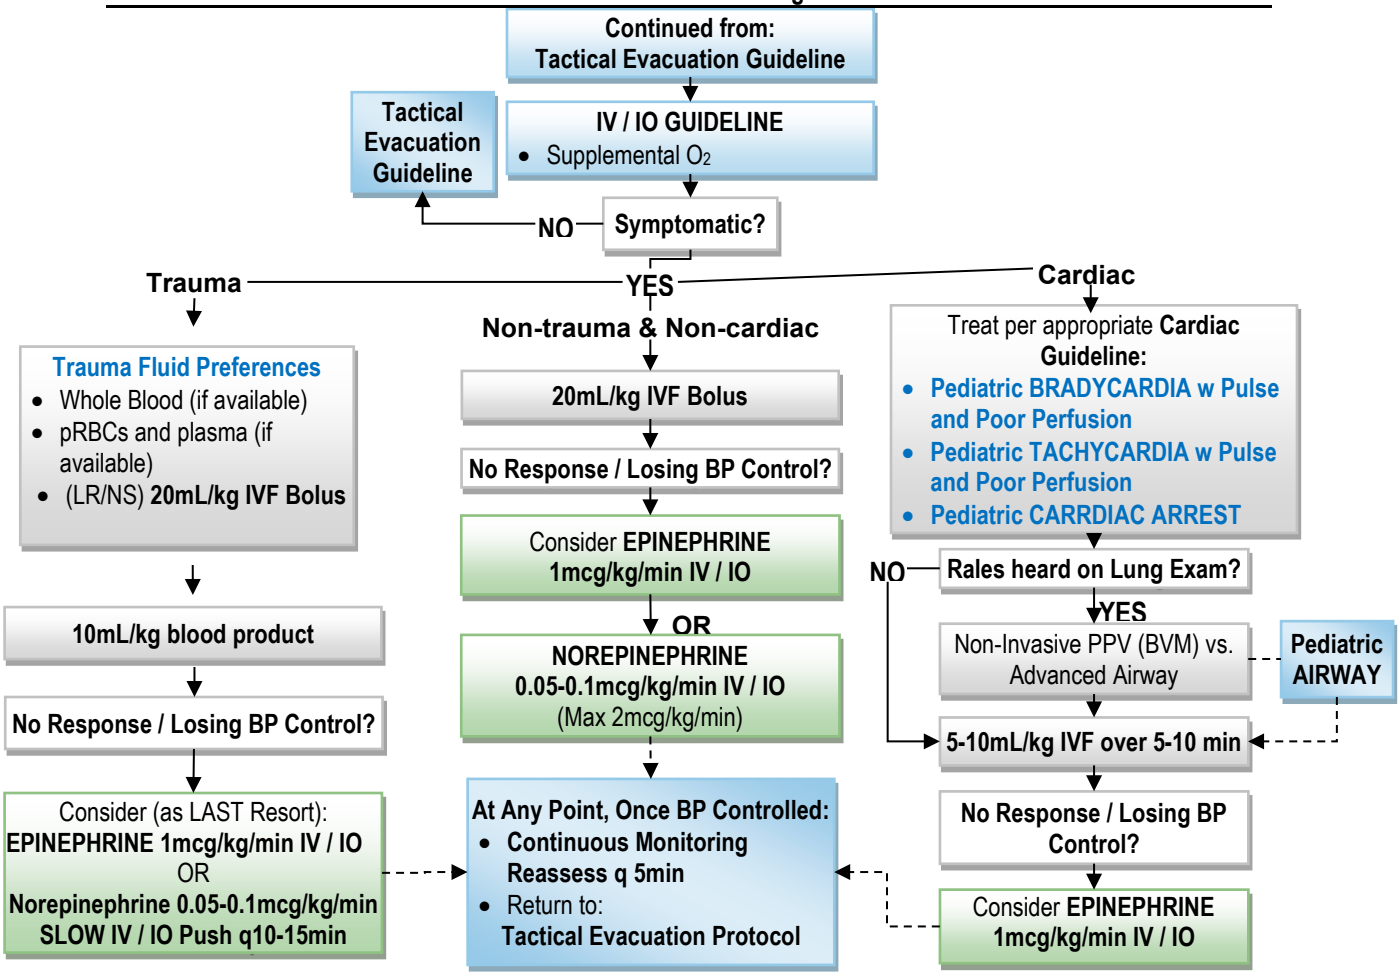


Pearls:

- **Optimize Hemostasis:**
  - **Hemorrhagic trauma with NO significant head injury:** Should target maintaining SBP >100. Casualties able to maintain SBP >100 do not need immediate fluid resuscitation.
  - **Hemorrhagic trauma WITH significant head injury:** should target maintaining SBP >110
  - If SBP falls <100 (with TBI <110), transition to Enroute Damage Control Resuscitation guideline.

Pediatric HYPOTENSION / SHOCK

Signs and Symptoms:	Differential Diagnosis:
• Restlessness / Confusion • Weakness / Dizziness • Tachycardia • Pale, Cool, Clammy Skin • Delayed Capillary Refill • Hypotension • Nausea / Vomiting • Responsiveness / Lethargy	• Shock: Hypovolemic, Cardiogenic, Septic, Neurogenic, Anaphylactic • Cardiac Arrhythmia • Pulmonary Embolus • Tension Pneumothorax • Medication Effect / OD • Vasovagal Episode • Dehydration • Congenital Heart Disease



Pearls:

- **Hypotension in pediatric patients is defined as a SBP less than 70 + [2 x age (yr)].**
- Decreasing heart rate with worsening neuro or clinical exam may be a sign of impending collapse in pediatric patients
- Consider all the causes of shock and treat per appropriate protocol.
- Avoid Pressors as able (unless distributive or cardiogenic shock) Continue IVFs for trauma: Optimize hemostasis and correct volume loss.

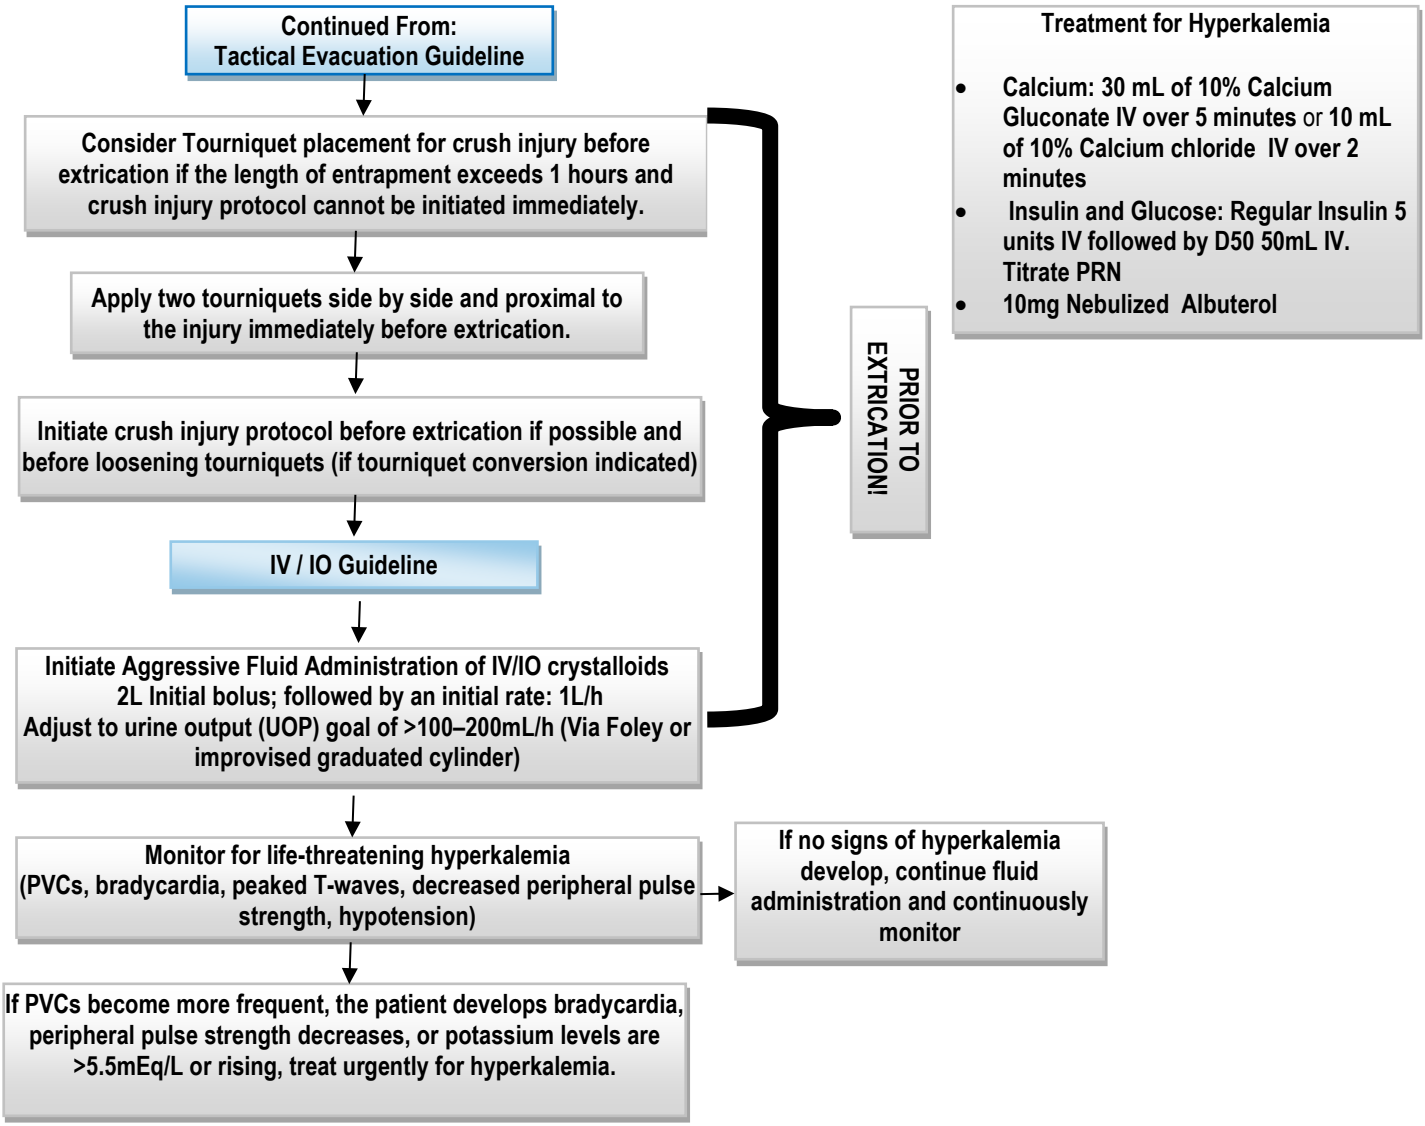
CRUSH SYNDROME

Signs and Symptoms:

- Entrapped extremity (as little as 1hr)
- Erythema, ecchymosis, abrasion
- Swelling, tense muscle compartment

Complications:

- Hyperkalemia
- Hypocalcemia
- Compartment Syndrome
- Rhabdomyolysis
- Arrhythmia
- Hypotension



Continued From:
Tactical Evacuation Guideline
Consider Tourniquet placement for crush injury before extrication if the length of entrapment exceeds 1 hours and crush injury protocol cannot be initiated immediately.
Apply two tourniquets side by side and proximal to the injury immediately before extrication.
Initiate crush injury protocol before extrication if possible and before loosening tourniquets (if tourniquet conversion indicated)
IV / IO Guideline
Initiate Aggressive Fluid Administration of IV/IO crystalloids
2L Initial bolus; followed by an initial rate: 1L/h
Adjust to urine output (UOP) goal of >100–200mL/h (Via Foley or improvised graduated cylinder)
Monitor for life-threatening hyperkalemia
(PVCs, bradycardia, peaked T-waves, decreased peripheral pulse strength, hypotension)
If PVCs become more frequent, the patient develops bradycardia, peripheral pulse strength decreases, or potassium levels are >5.5mEq/L or rising, treat urgently for hyperkalemia.
If no signs of hyperkalemia develop, continue fluid administration and continuously monitor
PRIOR TO EXTRICATION!
Treatment for Hyperkalemia
Calcium: 30 mL of 10% Calcium Gluconate IV over 5 minutes or 10 mL of 10% Calcium chloride IV over 2 minutes
Insulin and Glucose: Regular Insulin 5 units IV followed by D50 50mL IV. Titrate PRN
10mg Nebulized Albuterol

Pearls:

- Crush syndrome can occur in as little as 1 hour of entrapment
- Tourniquets may delay life-threatening complications if fluid resuscitation and treatment cannot be immediately initiated
- Aggressive fluid resuscitation for Crush injury in the setting of noncompressible hemorrhage may increase hemorrhage. Balance the risk of uncontrolled hemorrhage against cardiotoxic effects of hyperkalemia.

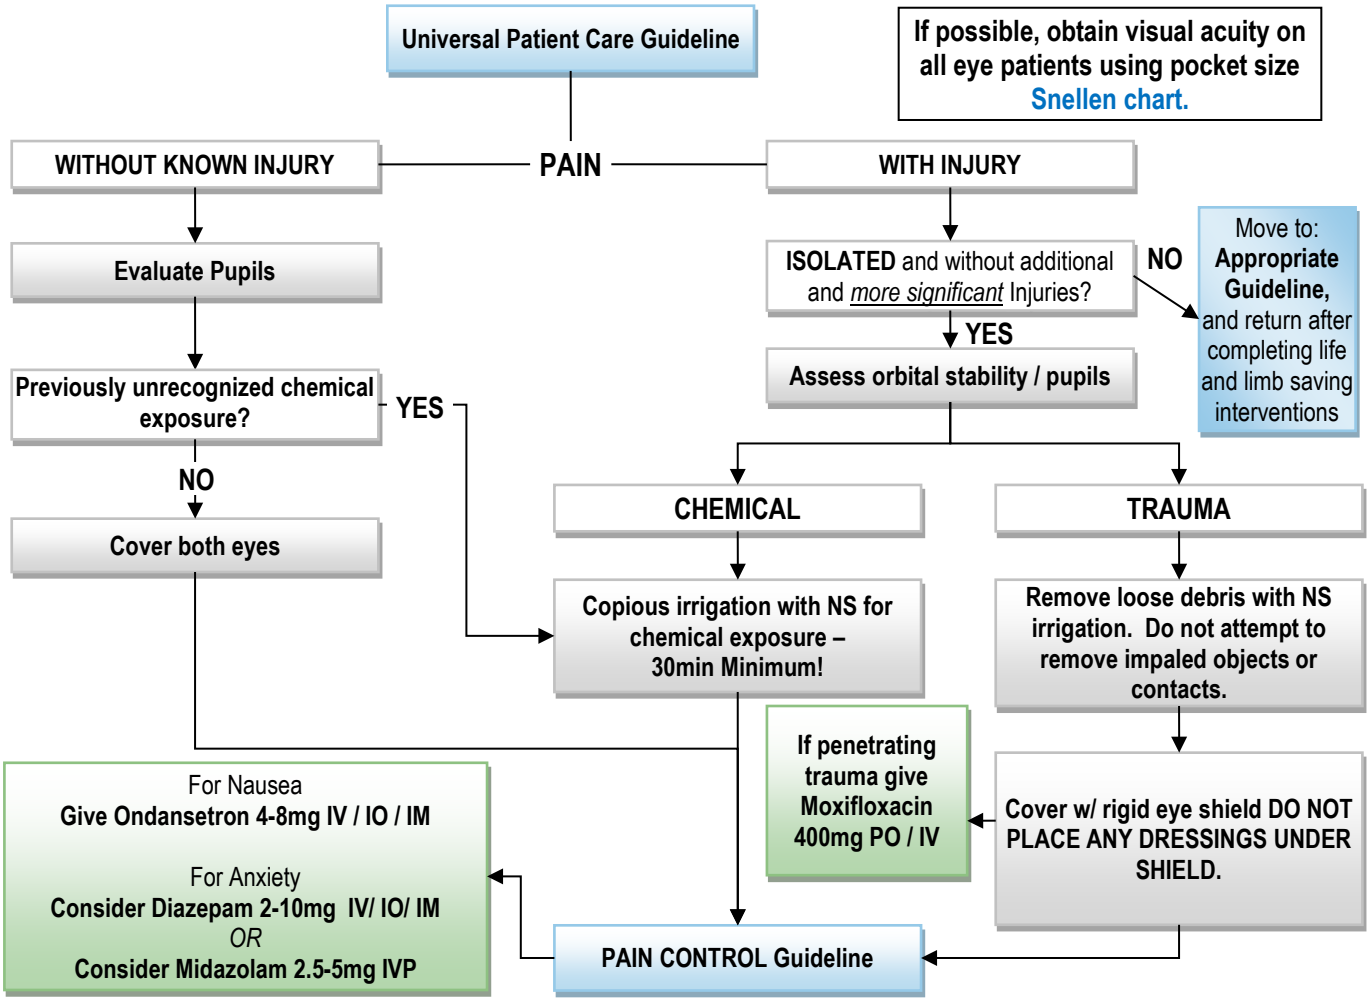
EYE INJURY / PAIN

Signs and Symptoms:

- **Pain, Swelling, Blood**
- **Decreased Visual Acuity / Blindness**
- **Deformity / Contusion**
- **Foreign Body**
- **Excessive Tearing**

Differential Diagnosis:

- **Abrasion / Laceration**
- **Globe Rupture / Orbital fracture**
- **Retinal Detachment**
- **Chemical / Thermal Burn**
- **Infection / Iritis**
- **CNS Event**
- **Glaucoma**
- **Retinal Vessel Occlusion**



Universal Patient Care Guideline
If possible, obtain visual acuity on all eye patients using pocket size Snellen chart.
PAIN
WITHOUT KNOWN INJURY
WITH INJURY
Evaluate Pupils
ISOLATED and without additional and more significant Injuries?
NO
Move to: Appropriate Guideline, and return after completing life and limb saving interventions
YES
Assess orbital stability / pupils
Previously unrecognized chemical exposure?
YES
NO
Cover both eyes
CHEMICAL
TRAUMA
Copious irrigation with NS for chemical exposure – 30min Minimum!
Remove loose debris with NS irrigation. Do not attempt to remove impaled objects or contacts.
If penetrating trauma give Moxifloxacin 400mg PO / IV
Cover w/ rigid eye shield DO NOT PLACE ANY DRESSINGS UNDER SHIELD.
For Nausea
Give Ondansetron 4-8mg IV / IO / IM
For Anxiety
Consider Diazepam 2-10mg IV/ IO/ IM
OR
Consider Midazolam 2.5-5mg IVP
PAIN CONTROL Guideline

Pearls:

- Antiemetics are essential to prevent increased IOP. Consider Benzo for anxiety.
- Use rigid eye shields, not pads, for traumatic injuries. Can use a soft pad on unaffected eye.
- Patching both eyes to decrease sympathetic eye movements has not been shown to improve visual outcome but may increase anxiety and will render patient unable to move independently.
- If globe is out of socket – do not attempt to replace. Cover with saline soaked gauze
- Copious irrigation is the cornerstone of treatment for chemical eye injuries. 30 min is the minimum amount of time to irrigate. Utilize Morgan lens if available.
    - The use of a nasal cannula across the bridge of the nose attached to 1L of NS will also work.

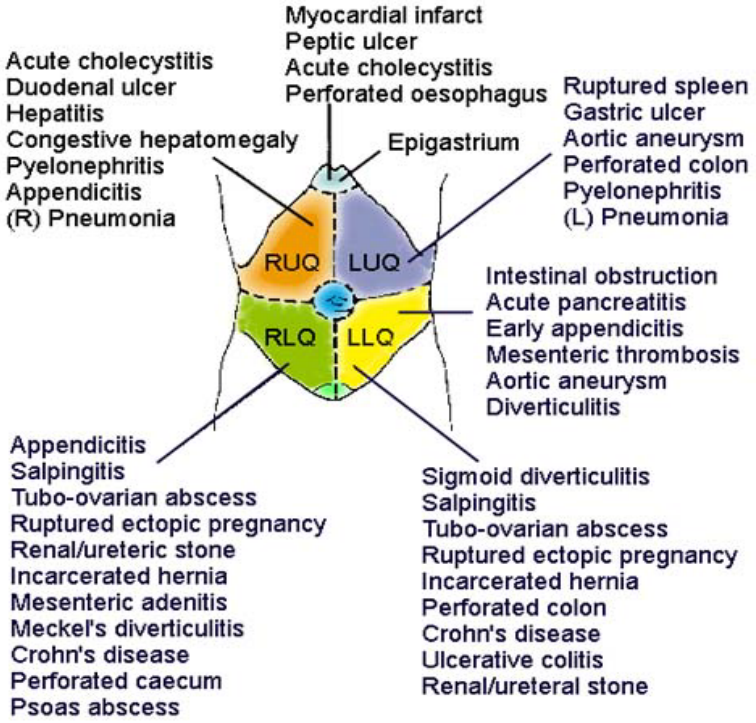
ABDOMINAL PAIN

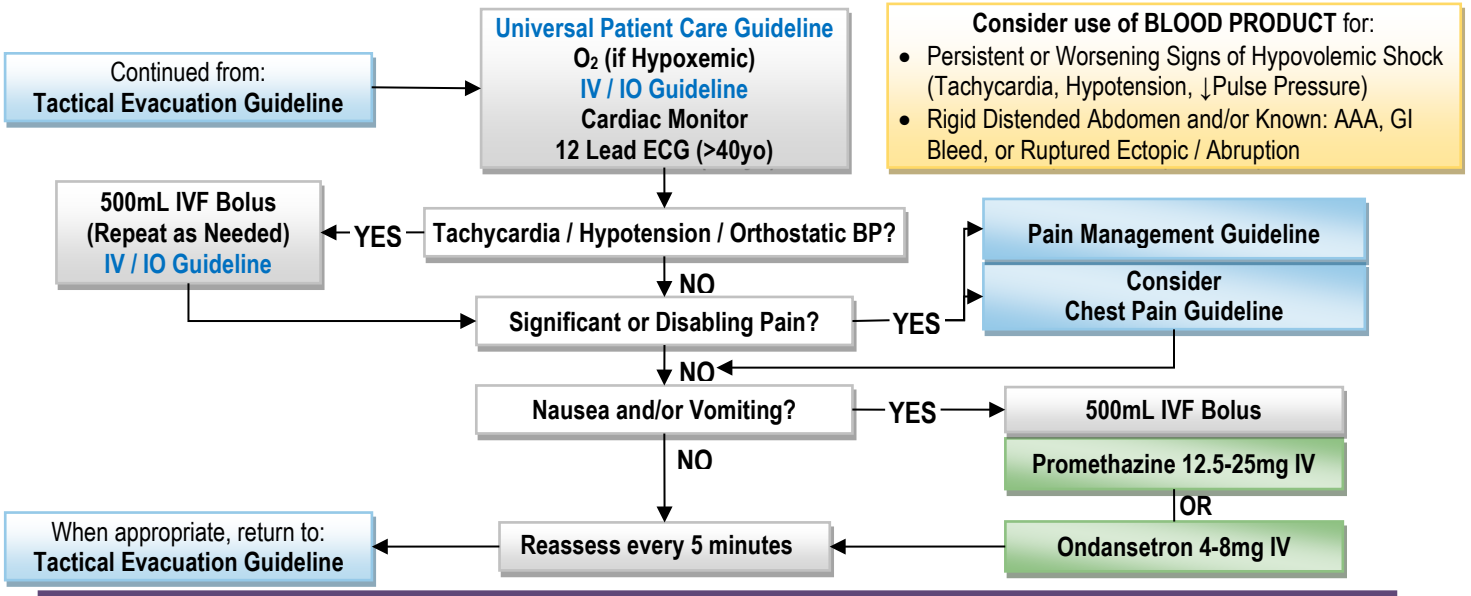
Signs and Symptoms:

- **Pain (RUQ, RLQ, LUQ, LLQ) (Location / Migration / Radiation)**
- **Tenderness**
- **Nausea / Vomiting**
- **Diarrhea (Bloody?)**
- **Dysuria**
- **Constipation**
- **Vaginal Bleeding / Discharge**
- **Distention**
- **Guarding / Rigidity**

Associated symptoms:

- **Fever, Headache, Weakness, Malaise / Fatigue, Myalgia, Cough, Mental Status Changes, Rash**





Pearls:

- Maintain a high index of suspicion for ectopic pregnancy as a cause of abdominal pain in females of childbearing age.
- Antacids should be avoided in patients with renal disease.
- Patients older than 50 are at increased risk for life-threatening diagnoses (e.g., AAA).
- Appendicitis presents with vague, periumbilical pain that migrates to the RLQ. This classic presentation may not be present in some patients.
- Repeat VS after each intervention. In non-traumatized patients, may repeat fluid bolus PRN depending on patient condition and VS. In trauma patients, fluid boluses should be used in accordance with hypotensive resuscitation guidelines (see Multiple Trauma Guideline).
- Choose the lower promethazine dosage for patients likely to experience sedative effects (e.g., elderly).

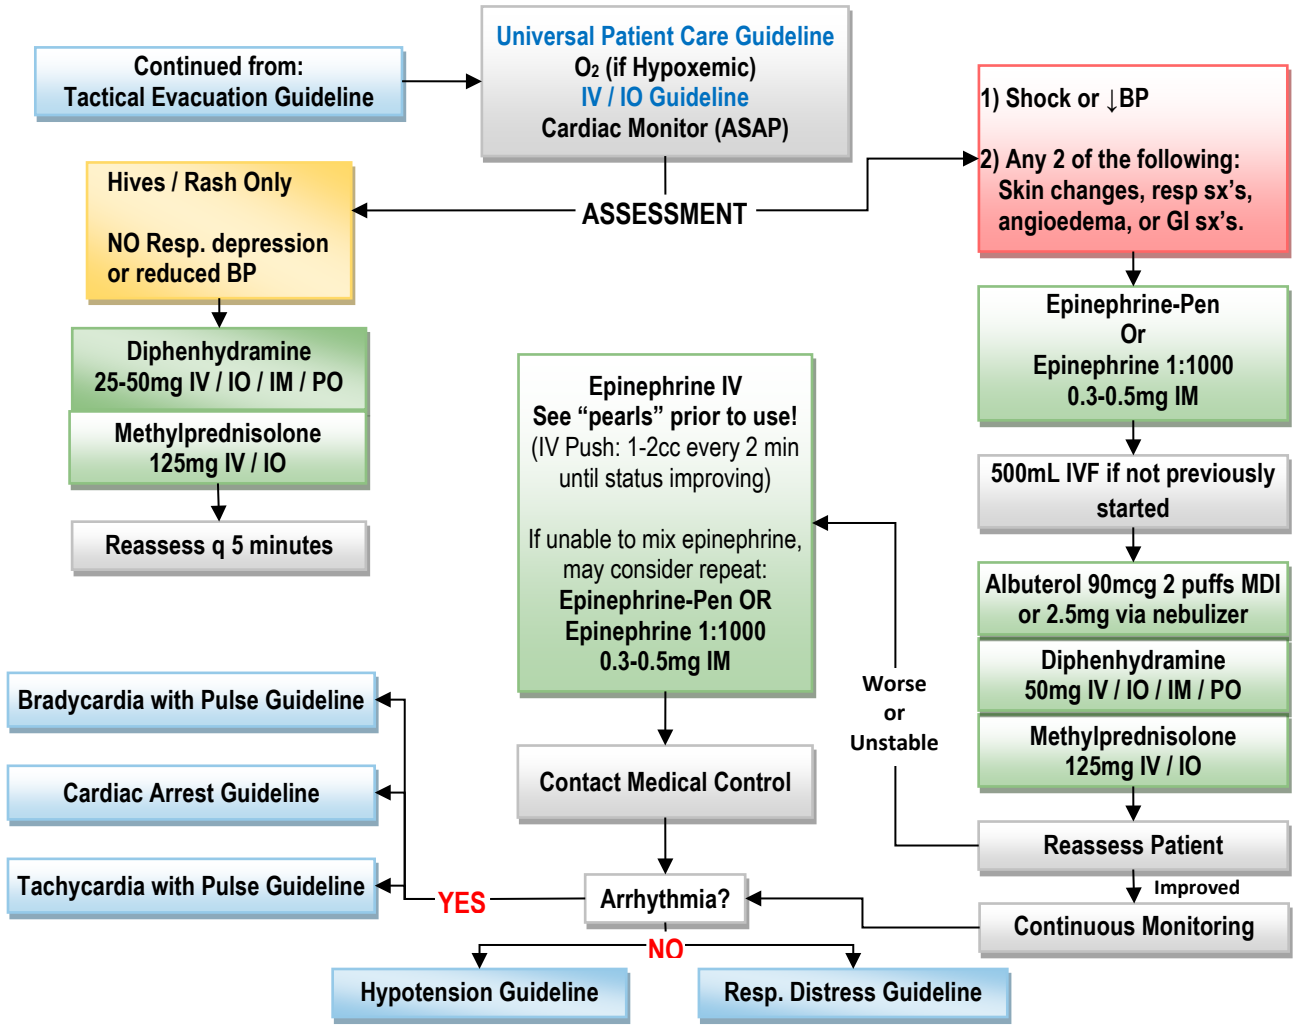
ALLERGIC REACTION

Signs and Symptoms:

- Itching or Hives
- Cough / Wheeze / Resp. Distress
- Chest / Throat Tightness
- Difficulty Swallowing
- Hypotension or Shock
- Edema
- Nausea / Vomiting

Differential Diagnosis:

- Urticaria (rash only)
- Shock (other than anaphylactic)
- Angioedema
- Aspiration / Airway Obstruction
- Asthma or COPD
- Pulmonary Edema / CHF



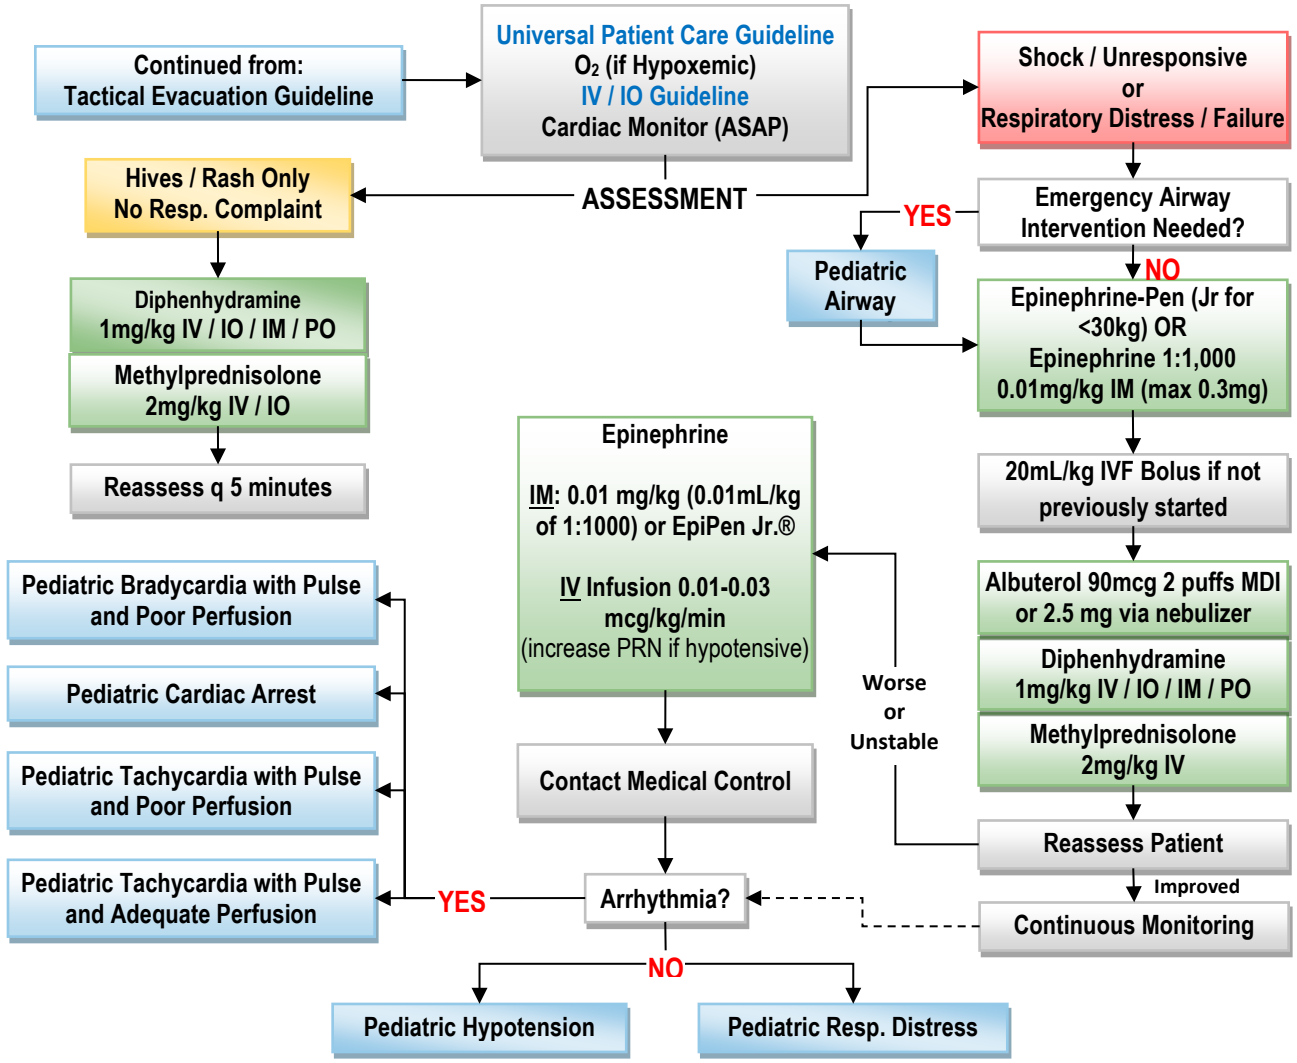
Continued from: Tactical Evacuation Guideline
Universal Patient Care Guideline
O2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)
ASSESSMENT
Hives / Rash Only
NO Resp. depression or reduced BP
Diphenhydramine 25-50mg IV / IO / IM / PO
Methylprednisolone 125mg IV / IO
Reassess q 5 minutes
1) Shock or ↓BP
2) Any 2 of the following: Skin changes, resp sx's, angioedema, or GI sx's.
Epinephrine-Pen Or Epinephrine 1:1000 0.3-0.5mg IM
500mL IVF if not previously started
Albuterol 90mcg 2 puffs MDI or 2.5mg via nebulizer
Diphenhydramine 50mg IV / IO / IM / PO
Methylprednisolone 125mg IV / IO
Reassess Patient
Improved
Continuous Monitoring
Epinephrine IV
See "pearls" prior to use!
(IV Push: 1-2cc every 2 min until status improving)
If unable to mix epinephrine, may consider repeat:
Epinephrine-Pen OR
Epinephrine 1:1000
0.3-0.5mg IM
Worse or Unstable
Contact Medical Control
Arrhythmia?
YES
NO
Bradycardia with Pulse Guideline
Cardiac Arrest Guideline
Tachycardia with Pulse Guideline
Hypotension Guideline
Resp. Distress Guideline

Pearls:

- Use caution prior to giving epinephrine IV to patients >50yo, pregnant, have a history of cardiac disease, or have HR >150. Epinephrine can precipitate dysrhythmias / ischemia – all patients should be on monitors and have 12-lead ECG.
- **Epinephrine**:
  - IM: 0.3-0.5mg (0.3-0.5 mL 1:1000) or EpiPen®
  - IV Bolus: 100 mcg over 5-10 min; mix 0.1mg (0.1 mL of 1:1000 in 10mL NS, and infuse over 5-10 min)
  - IV Infusion: Start at 1 mcg/min; mix 1mg (1 mL of 1:1000 in 500 mL NS, and infuse at 0.5 mL/min; titrate as needed
- The shorter the interval from contact to symptoms, the more severe the reaction.

Pediatric ALLERGIC REACTION

Signs and Symptoms:	Differential Diagnosis:
• Itching or Hives	• Urticaria (rash only)
• Cough / Wheeze / Resp. Distress	• Anaphylaxis (2 or more systems)
• Chest/Throat tightness	• Shock (other than anaphylactic)
• Difficulty Swallowing	• Angioedema
• Hypotension or Shock	• Aspiration / Airway Obstruction
• Edema	• Asthma or COPD
• Nausea / Vomiting	• Pulmonary Edema / CHF



Continued from: Tactical Evacuation Guideline
Universal Patient Care Guideline
O_2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)
Shock / Unresponsive or Respiratory Distress / Failure
Hives / Rash Only No Resp. Complaint
ASSESSMENT
YES
Emergency Airway Intervention Needed?
Pediatric Airway
NO
Diphenhydramine 1mg/kg IV / IO / IM / PO
Methylprednisolone 2mg/kg IV / IO
Reassess q 5 minutes
Epinephrine-Pen (Jr for <30kg) OR Epinephrine 1:1,000 0.01mg/kg IM (max 0.3mg)
20mL/kg IVF Bolus if not previously started
Albuterol 90mcg 2 puffs MDI or 2.5 mg via nebulizer
Diphenhydramine 1mg/kg IV / IO / IM / PO
Methylprednisolone 2mg/kg IV
Reassess Patient
Improved
Continuous Monitoring
Epinephrine
IM: 0.01 mg/kg (0.01mL/kg of 1:1000) or EpiPen Jr.®
IV Infusion 0.01-0.03 mcg/kg/min
(increase PRN if hypotensive)
Worse or Unstable
Contact Medical Control
Arrhythmia?
YES
NO
Pediatric Bradycardia with Pulse and Poor Perfusion
Pediatric Cardiac Arrest
Pediatric Tachycardia with Pulse and Poor Perfusion
Pediatric Tachycardia with Pulse and Adequate Perfusion
Pediatric Hypotension
Pediatric Resp. Distress

Pearls:

- Epinephrine can precipitate dysrhythmias / ischemia – all patients should be on monitors and have 12-lead ECG.
- The shorter the interval from contact to symptoms, the more severe the reaction.

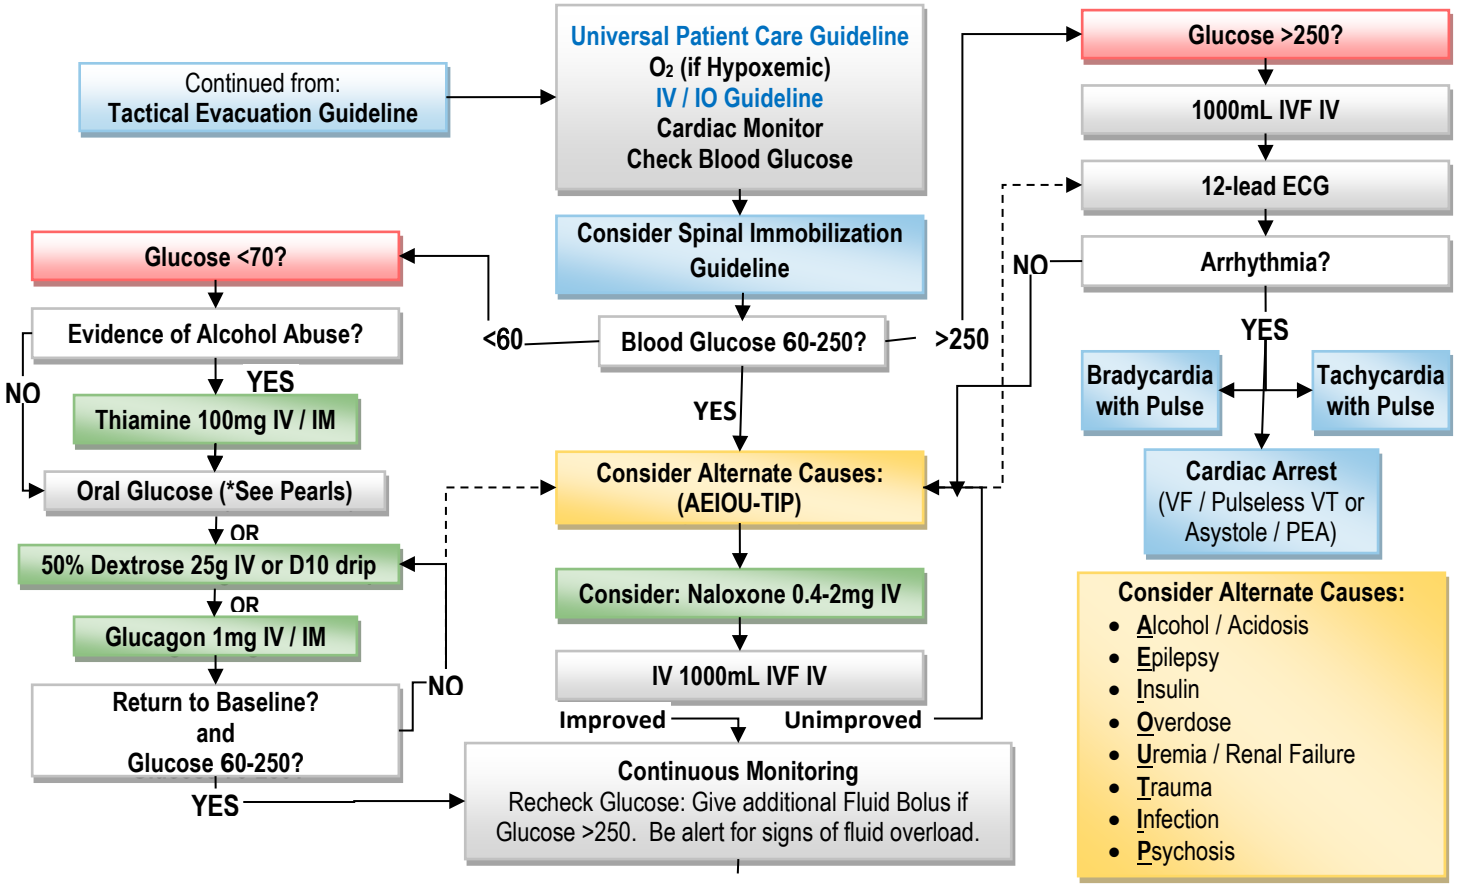
ALTERED MENTAL STATUS

Signs and Symptoms:

- Decreased Mental Status / Coma
- Bizarre Behavior
- Somnolence
- Diaphoresis / Dry, Red Skin
- Polyuria / Polydipsia
- Sweet / Fruity Breath
- Altered Respirations
- Signs of Trauma
- Fever

Differential Diagnosis:

- Head Trauma
- Stroke
- CNS Tumor / Mass / Bleed / Infection
- Thyroid Dysfunction
- Hyperglycemia / Hypoglycemia
- Diabetic Ketoacidosis
- Toxic Exposure
- Environment (Hyperthermia / Hypothermia)
- Hypoxia
- Psychiatric Disorders
- Seizure Disorder
- Sepsis



Pearls:

- Be aware of AMS as a presentation of environmental exposure / toxins / hazmat – use personal protection accordingly / decontamination.
- **Recheck blood glucose after each intervention**.
- ***Oral glucose okay if patient alert, protecting airway, and solution available**. Proteins + complex carbs (e.g., sandwich, granola) are better, longer lasting glucose source than simple sugars.
- EKG should be obtained in all suspected toxin or diabetic ketoacidosis cases – evaluate for tall, peaked T-waves (hyperkalemia) or QRS widening >100ms (toxins).
- Restrain patient as necessary for their safety and crewmembers safety during flight.
- Glucagon may cause nausea / vomiting – should have anti-emetic prepared.

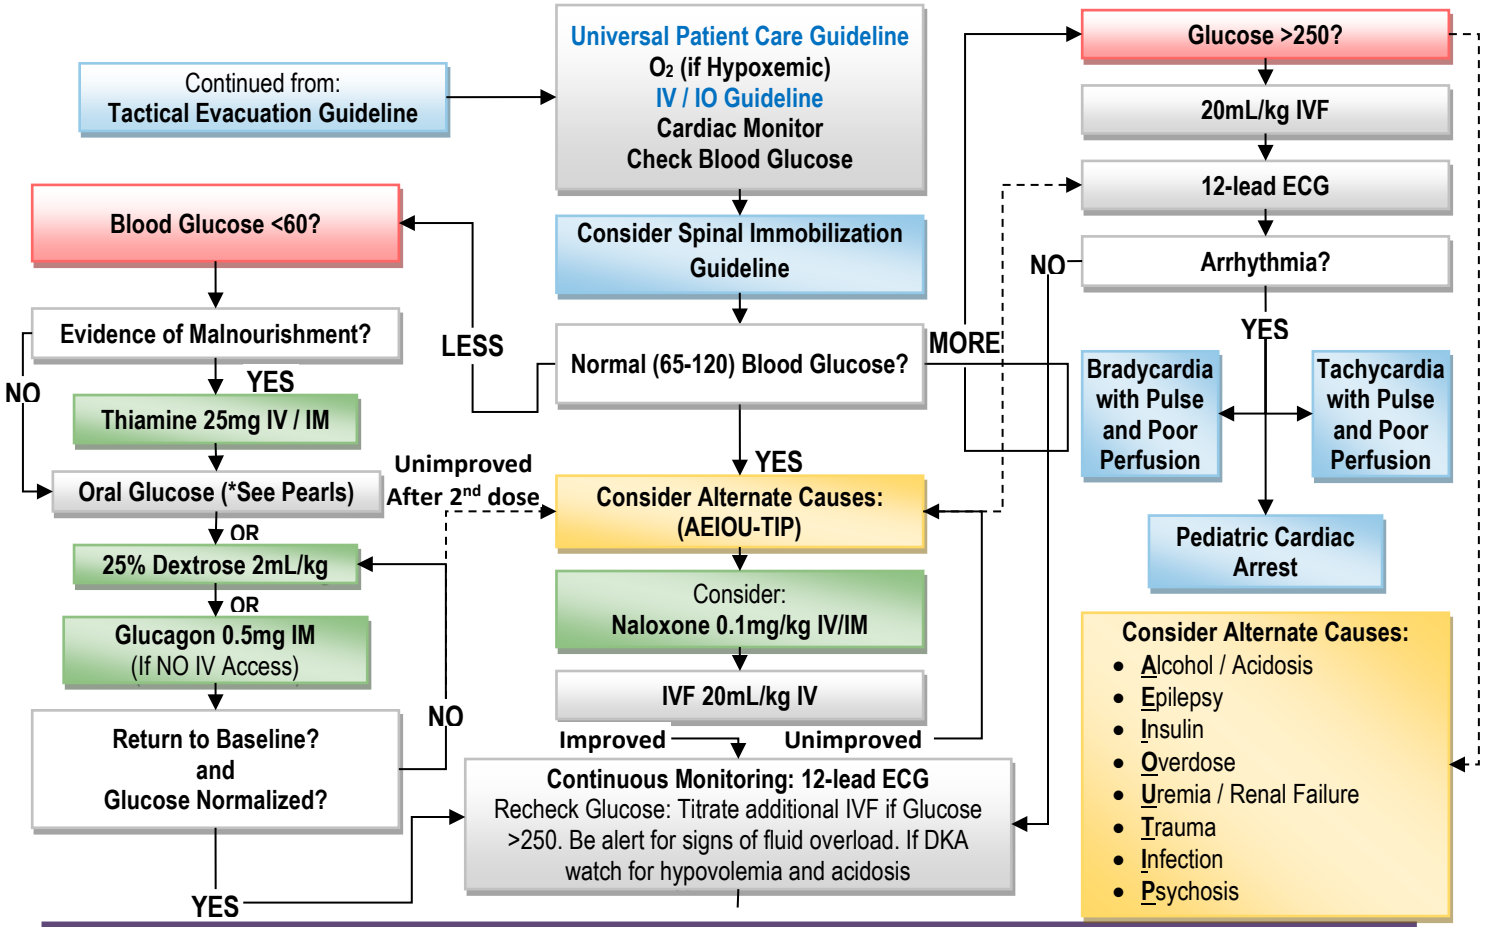
Pediatric AMS

Signs and Symptoms:

- Decreased Mental Status / Coma
- Bizarre Behavior
- Somnolence
- Diaphoresis / Dry, Red Skin
- Polyuria / Polydipsia
- Sweet / Fruity Breath
- Altered Respirations
- Signs of Trauma
- Fever

Differential Diagnosis:

- Head Trauma
- Stroke
- CNS Tumor / Mass / Bleed / Infection
- Thyroid Dysfunction
- Hyperglycemia / Hypoglycemia
- Diabetic Ketoacidosis
- Toxic Ingestion
- Environment (Hyperthermia / Hypothermia)
- Hypoxia
- Psychiatric Disorders
- Seizure Disorder
- Sepsis



Pearls:

- Be aware of Altered Mental Status (AMS) as a presentation of environmental exposure / toxins / hazmat – use personal protection accordingly / decontamination.
- **Recheck blood glucose after each intervention**.
- ***Oral glucose okay if patient alert, protecting airway, and solution available**. Proteins + complex carbs (e.g., sandwich, granola) are better, longer lasting glucose source than simple sugars.
- EKG should be obtained in all suspected toxin or diabetic ketoacidosis cases – evaluate for tall, peaked T-waves (hyperkalemia) or QRS widening >100ms (toxins).
- Glucagon may cause nausea / vomiting – should have anti-emetic prepared.

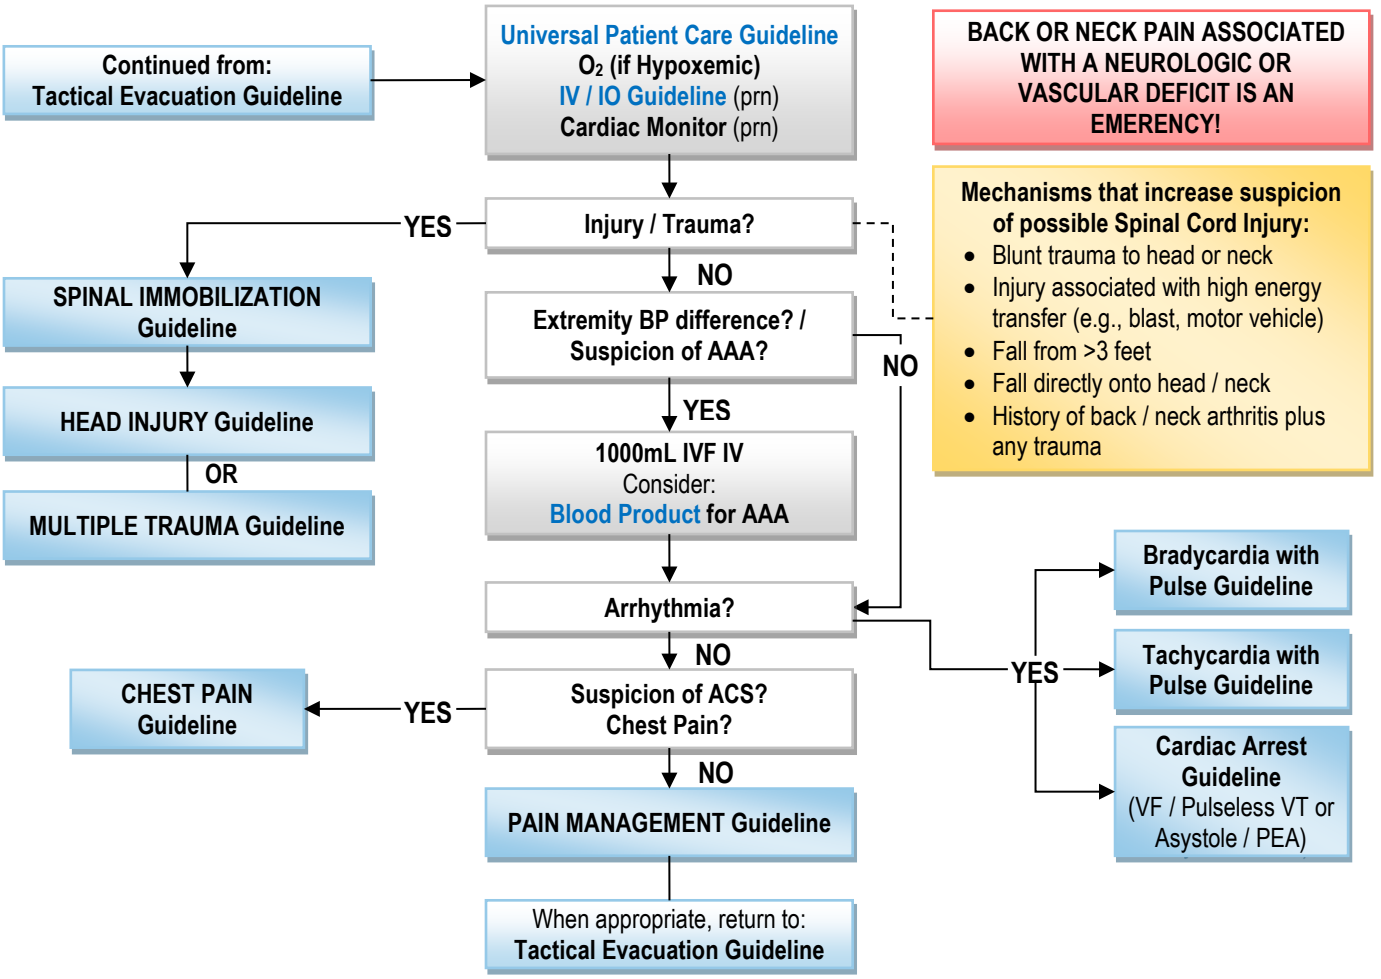
BACK and NECK PAIN

Signs and Symptoms:

- **Pain**
- **Swelling**
- **Pain with Motion**
- **Weakness / Numbness**
- **Bowel / Bladder Dysfunction**

Differential Diagnosis:

- **Muscle Spasm / Strain**
- **Degenerative Disc Disease**
- **Fracture**
- **Kidney Stone / Infection**
- **Abdominal Aortic Aneurysm**
- **Pneumonia / PE**
- **Cauda Equina Syndrome**
- **Tumor / Mass / Infection**
- ***Thoracic Pain:*** **Thoracic or abdominal aortic aneurysm**

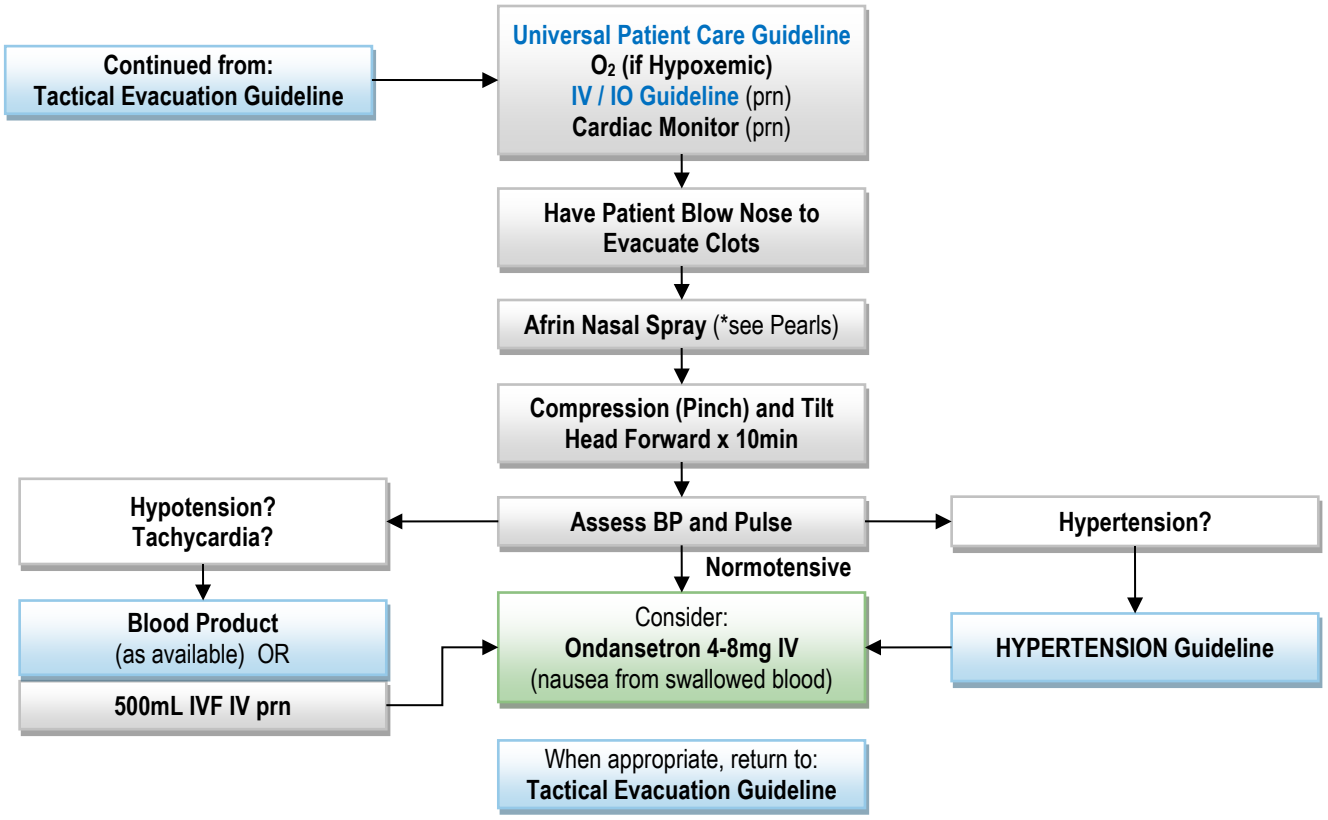


Pearls:

- Examine: mental status, HEENT, neck, chest, lungs, abdomen, back, extremities, neurologic.
- Abdominal aortic aneurysm is a concern in hypertensive / diabetic / >50yo populations – feel for pulsatile abdominal mass. Symptoms may mimic kidney stones.
- Patients with trauma / midline tenderness should be immobilized.
- Any bowel / bladder incontinence is significant and may represent a true surgical emergency (**Cauda Equina Syndrome**).

EPISTAXIS

Signs and Symptoms:	Differential Diagnosis:
• **Bleeding From One or Both Nares** • **Pain** • **Nausea / Vomiting** • **Nasal Deformity**	• **Trauma** • **Infection** • **Allergic / Chemical Rhinitis** • **Nose Picking** • **Lesions (Polyp, Ulcer)** • **Hypertension** • **Anticoagulant Therapy** • **Thrombocytopenia (ITP)**



Pearls:

- ***Avoid Afrin in patients who have a diastolic blood pressure >110** or known coronary artery disease.
- It is better to overestimate the amount of blood lost with epistaxis.
- Anticoagulants including aspirin, ibuprofen, and even herbals (ginseng) can lead to increased bleeding.
- Firm pressure should be applied for compression. Pressure should not be applied over the bridge of the nose, but instead under the bony portion to effectively compress vessels. Do not release pressure prior to the 10 minutes mark to check bleeding.
- Hypertensive patients will often not stop bleeding until BP is controlled.
- Re-bleeding is common with epistaxis.

FEVER

Signs and Symptoms:

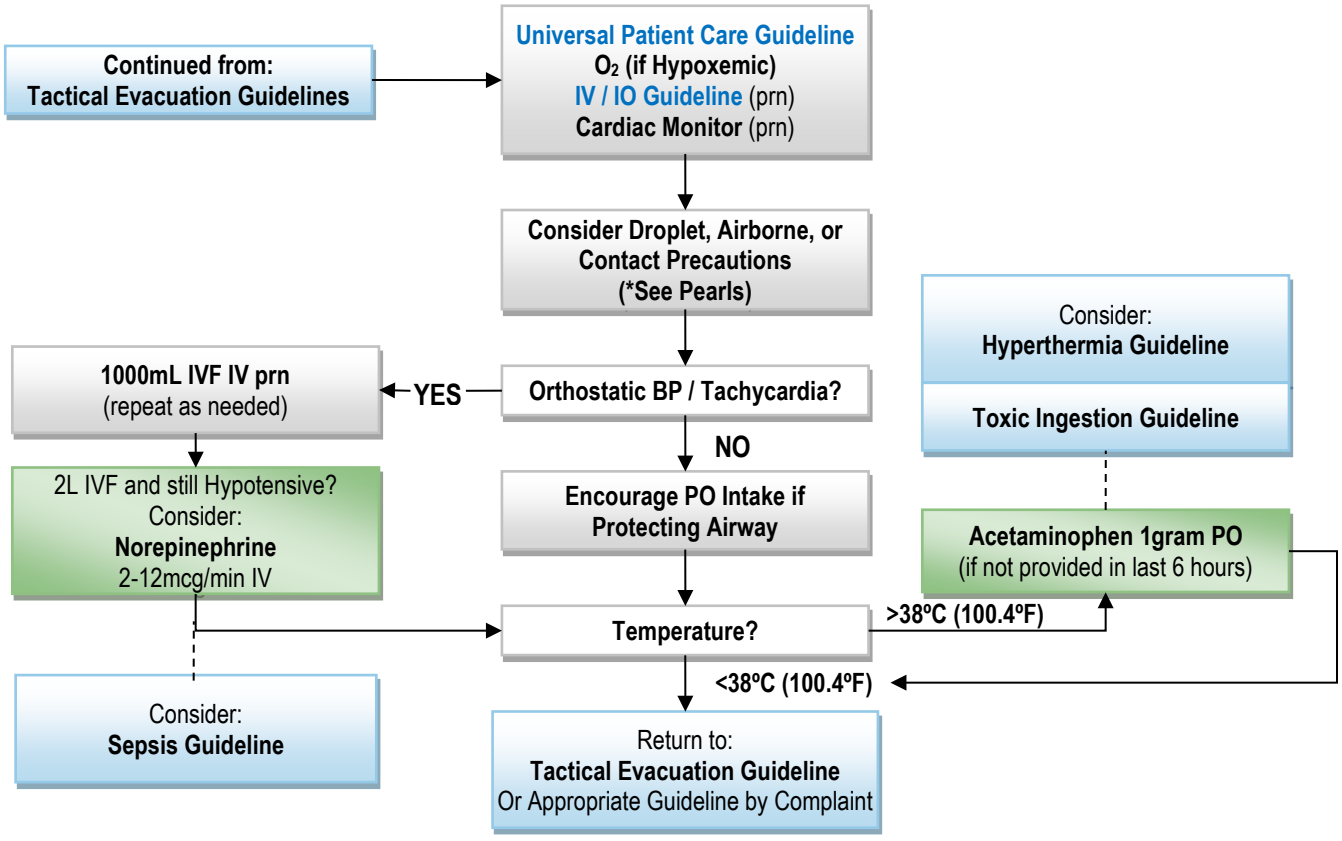
- **Warm**
- **Flushed**
- **Diaphoretic**
- **Chills**

Associated Symptoms:

- **Myalgias, Cough, Chest Pain, Headache, Dysuria, Abdominal Pain, Mental Status Change, Rash, Stiff Neck**

Differential Diagnosis:

- **Infection / Sepsis**
- **Cancer / Tumor / Lymphoma**
- **Medication / Drug Reaction**
- **Connective Tissue Diseases**
- **Hyperthyroidism**
- **Heat Stroke**
- **Meningitis**



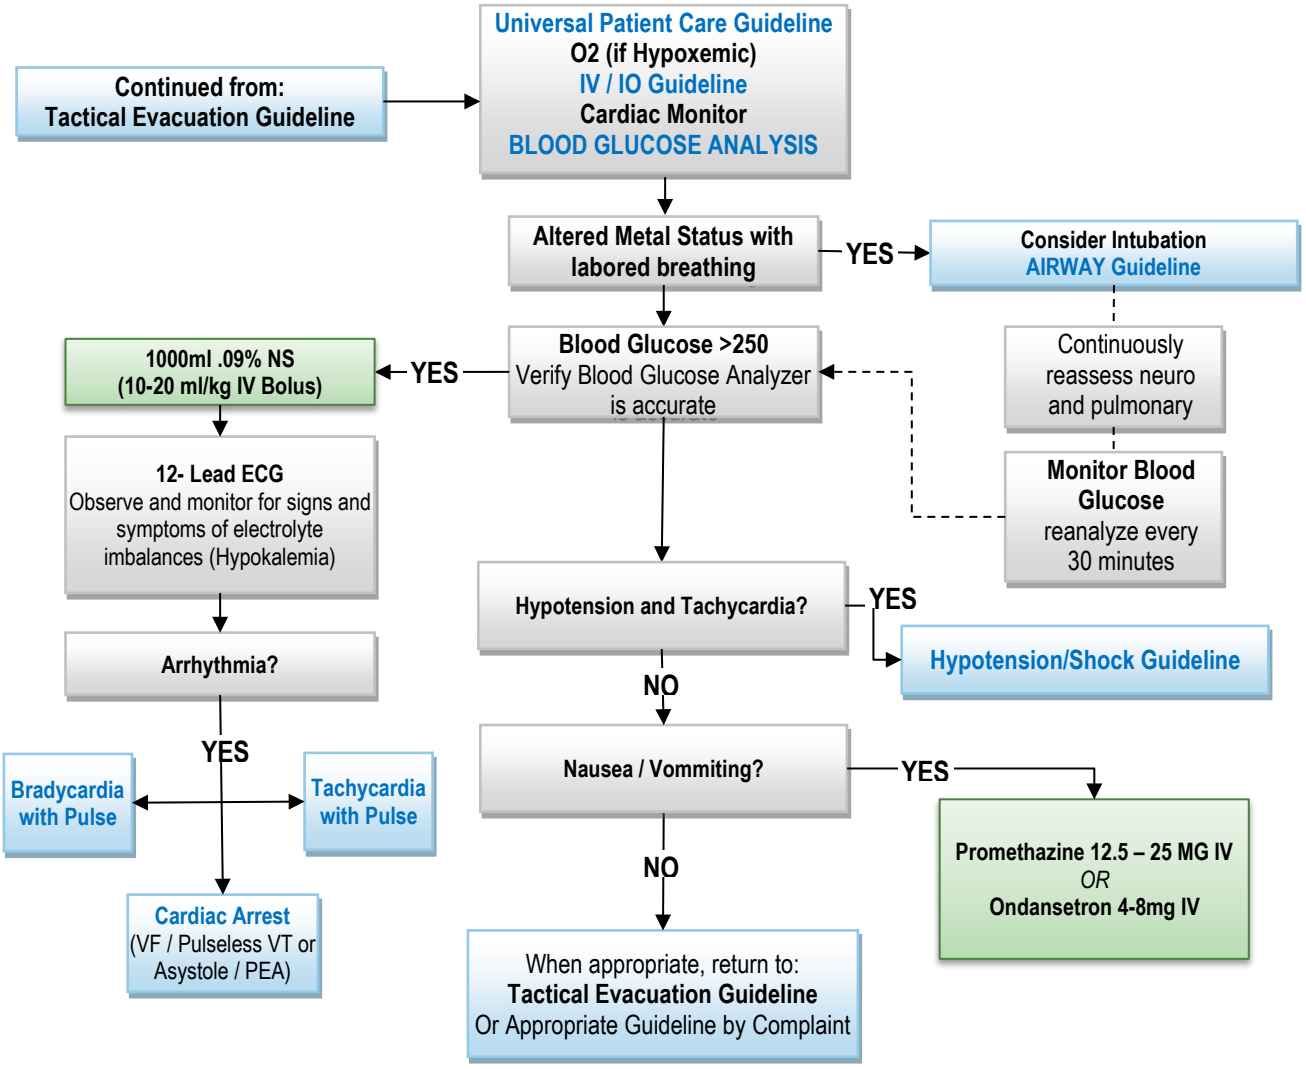
Continued from:
Tactical Evacuation Guidelines
Universal Patient Care Guideline
O2 (if Hypoxemic)
IV / IO Guideline (prn)
Cardiac Monitor (prn)
Consider Droplet, Airborne, or Contact Precautions (*See Pearls)
Orthostatic BP / Tachycardia?
YES
1000mL IVF IV prn (repeat as needed)
2L IVF and still Hypotensive? Consider: Norepinephrine 2-12mcg/min IV
Consider: Sepsis Guideline
NO
Encourage PO Intake if Protecting Airway
Temperature?
>38ºC (100.4ºF)
<38ºC (100.4ºF)
Consider: Hyperthermia Guideline
Toxic Ingestion Guideline
Acetaminophen 1gram PO (if not provided in last 6 hours)
Return to: Tactical Evacuation Guideline Or Appropriate Guideline by Complaint

Pearls:

- Fever may not be present in immunocompromised, elderly, or those on immunosuppressive drugs.
- All fever is not due to infection – evaluate for environmental / thyroid / toxic etiology.
- *Appropriate precautions should be used for personal protection when transporting patients with contagious disease:
  - Airborne: standard PPE plus N-95 mask and NRB or surgical mask on patient. Used for tuberculosis, measles, varicella, or other infections spread by droplets.
  - Droplet: standard surgical mask for provider and patient. Use with: influenza, meningitis, mumps, streptococcal pharyngitis.
  - Contact: standard PPE with strict hand-washing. (MRSA, scabies, varicella-zoster)
- It is better to use more PPE than is necessary.
- Acetaminophen may also be given PR if suppository form available and patient not tolerant of PO medications.

HYPERGLYCEMIA

Signs and Symptoms:	Differential Diagnosis:
• Polyuria • Polydipsia • Weakness, fatigue • Nausea, vomiting • Change in LOC • Hypotension • Tachycardia • Seizures, coma • Fruity Breath Odor	• DKA (Ketoacidosis) • Hyperosmolar Hyperglycemic Syndrome (HHS) • Head Trauma • Stroke • Hypo/Hyperthermia • Toxic Exposure

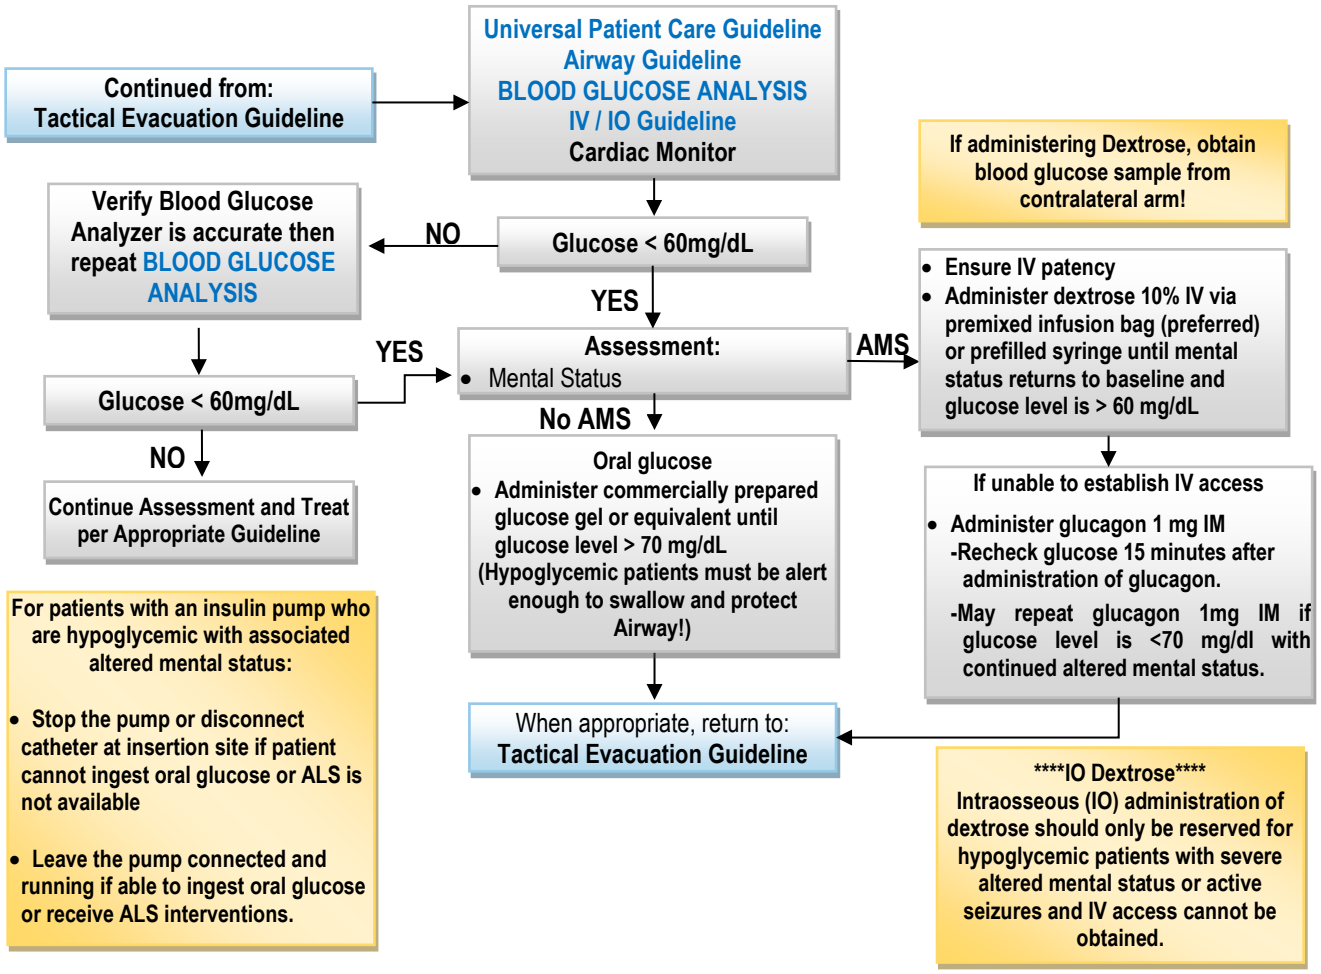


Pearls:

- If insulin is available, treat with low dose infusion, 0.1 units/kg/h
- Too rapid drop in blood glucose can cause hypoglycemia.
- Rapid drop in blood glucose levels can lead to shifts extracellular osmolality which can lead to cerebral edema
- The most common electrolyte imbalance is hypokalemia.
- Identify and treat underlying cause (infection, trauma)

HYPOGLYCEMIA

Signs and Symptoms:	Differential Diagnosis:
• Diaphoresis and pallor • Neuroglycopenic manifestations/ AMS • Tremor • Palpitations • Anxiety	• Environmental Exposure • Postprandial syndrome • CNS Dysfunction • Toxic Ingestion • Metabolic disorders



Pearls:

- There are no statistically significant differences in the median recovery time to a GCS score of 15 following administration of D10% versus D50%. D10% may benefit patients by decreasing the likelihood of post-treatment hyperglycemia and reducing the likelihood of extravasation injury.
- Sulfonylureas (e.g., glyburide, glipizide) have long half-lives ranging from 12 – 60 hours. Patients with corrected hypoglycemia who are taking these agents are at particular risk for recurrent symptoms and frequently require hospital admission.
- Hypoglycemia may be detrimental to patients at risk for cerebral ischemia, such as victims of stroke, cardiac arrest, and head trauma.
- Oral glucose equivalents include 3 - 4 glucose tablets, 4 oz. fruit juice (e.g. orange juice), non-diet soda, 1 tablespoon of pure maple syrup, sugar, or honey. Oral glucose okay if patient alert, protecting airway, and solution available. Proteins + complex carbs (e.g., sandwich, granola) are better, longer lasting glucose source than simple sugars.

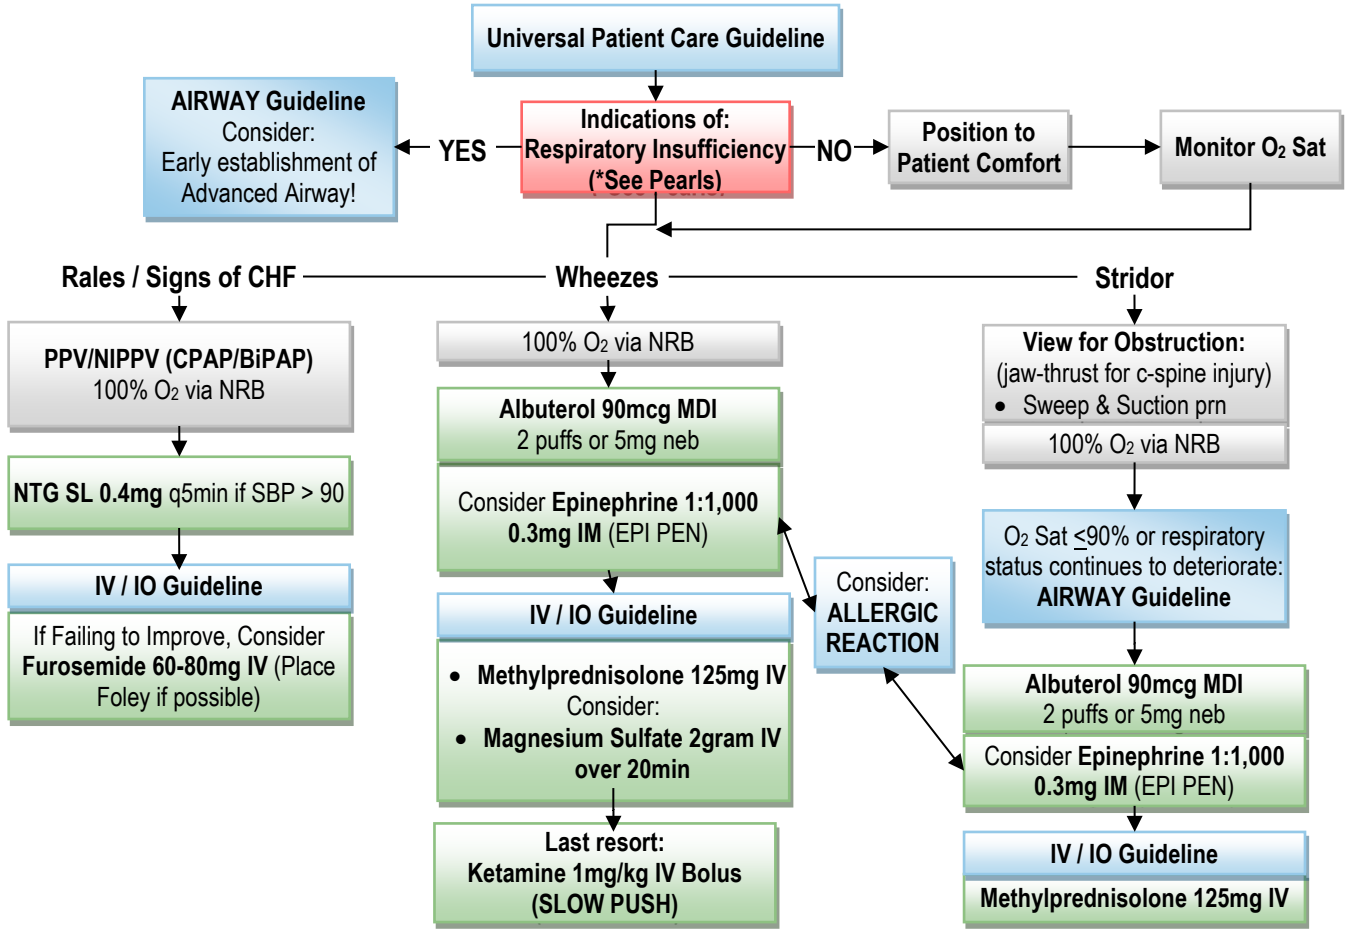
RESPIRATORY DISTRESS

Signs and Symptoms:

- **Shortness of Breath**
- **Pursed Lip Breathing**
- **Decreased Ability to Speak**
- **Tachypnea / Hyperpnea**
- **Wheezing / Rhonchi / Rales**
- **Use Accessory Muscles**
- **Fever / Cough**
- **Tachycardia**
- **Absent Breath Sounds (Emergent)**

Differential Diagnosis:

- **Asthma**
- **Anaphylaxis / Allergy**
- **Aspiration**
- **COPD**
- **Pleural Effusion**
- **Pneumonia**
- **Congestive Heart Failure / Cardiac**
- **Pulmonary Embolus**
- **Pneumothorax**
- **Pericardial Tamponade**
- **Hyperventilation**
- **Toxic Inhalation** (e.g., Cyanide, CO)

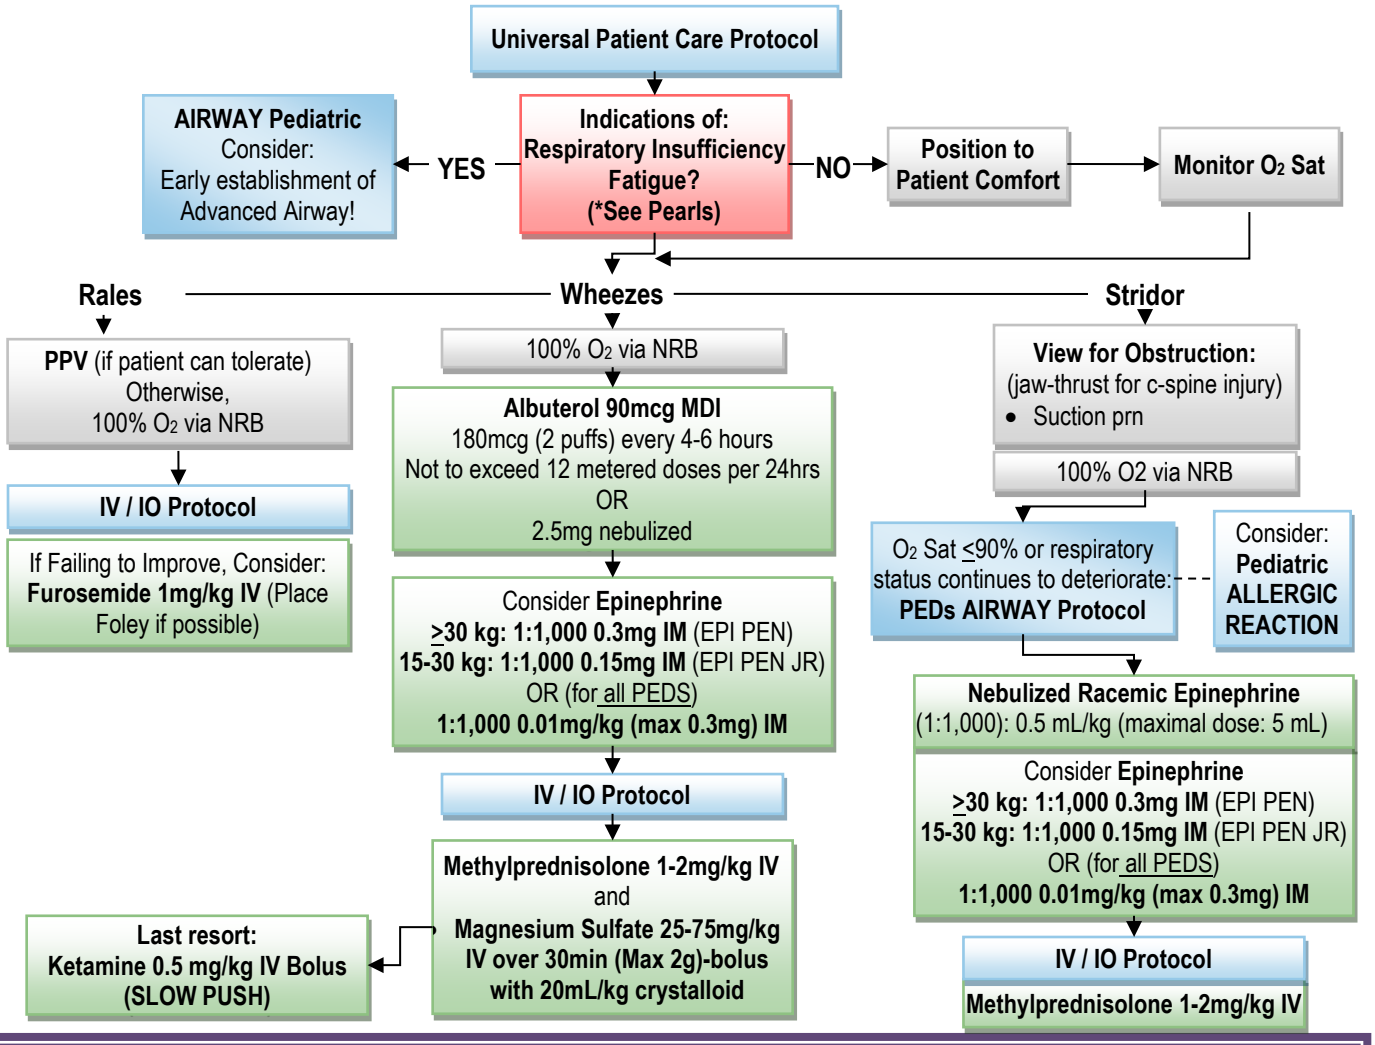


Pearls:

- **Signs of respiratory insufficiency**: Cyanosis, altered mental status / loss of consciousness, fatiguing, inability to speak, or inability to maintain O_2 sat >90% with supplemental O_2.
- Albuterol can be administered with spacer or short (6") section of ventilator tubing to increase delivery if patient unable to perform action appropriately. No max dose of albuterol, repeat as needed for continued wheezing.
- Lack of abnormal breath sounds does not always signify improvement. As respiratory status worsens, there may be inadequate air movement to produce these sounds.

PEDs RESPIRATORY DISTRESS

Signs and Symptoms:	Differential Diagnosis:
• **Shortness of Breath**	• **Asthma**
• **Tri-Pod Position**	• **Anaphylaxis / Allergy**
• **Pursed Lip Breathing**	• **Aspiration**
• **Decreased Ability to Speak**	• **Croup**
• **Tachypnea / Hyperpnea**	• **Pneumonia**
• **Wheezing / Rhonchi / Rales**	• **Epiglottitis**
• **Use Accessory Muscles**	• **Pneumothorax**
• **Fever / Cough**	• **Pericardial Tamponade**
• **Tachycardia**	• **Hyperventilation**
• **Absent Breath Sounds**	• **Toxic Inhalation** (e.g., Cyanide, CO)



Universal Patient Care Protocol
Indications of: Respiratory Insufficiency Fatigue? (*See Pearls)
YES
AIRWAY Pediatric Consider: Early establishment of Advanced Airway!
NO
Position to Patient Comfort
Monitor O2 Sat
Rales
Wheezes
Stridor
PPV (if patient can tolerate) Otherwise, 100% O2 via NRB
IV / IO Protocol
If Failing to Improve, Consider: Furosemide 1mg/kg IV (Place Foley if possible)
100% O2 via NRB
Albuterol 90mcg MDI 180mcg (2 puffs) every 4-6 hours Not to exceed 12 metered doses per 24hrs OR 2.5mg nebulized
Consider Epinephrine ≥30 kg: 1:1,000 0.3mg IM (EPI PEN) 15-30 kg: 1:1,000 0.15mg IM (EPI PEN JR) OR (for all PEDS) 1:1,000 0.01mg/kg (max 0.3mg) IM
IV / IO Protocol
Methylprednisolone 1-2mg/kg IV and Magnesium Sulfate 25-75mg/kg IV over 30min (Max 2g)-bolus with 20mL/kg crystalloid
Last resort: Ketamine 0.5 mg/kg IV Bolus (SLOW PUSH)
View for Obstruction: (jaw-thrust for c-spine injury)
• Suction prn
100% O2 via NRB
O2 Sat ≤90% or respiratory status continues to deteriorate: PEDs AIRWAY Protocol
Consider: Pediatric ALLERGIC REACTION
Nebulized Racemic Epinephrine (1:1,000): 0.5 mL/kg (maximal dose: 5 mL)
Consider Epinephrine ≥30 kg: 1:1,000 0.3mg IM (EPI PEN) 15-30 kg: 1:1,000 0.15mg IM (EPI PEN JR) OR (for all PEDS) 1:1,000 0.01mg/kg (max 0.3mg) IM
IV / IO Protocol
Methylprednisolone 1-2mg/kg IV

Pearls:

- **Signs of respiratory insufficiency**: Cyanosis, altered mental status / loss of consciousness, fatiguing, inability to speak, or inability to maintain O_2 sat >94% with supplemental O_2.
- **Albuterol can be administered with spacer or short (6") section of ventilator tubing to increase delivery if patient unable to perform action appropriately. No max dose of albuterol, repeat as needed for continued wheezing.**
- Lack of abnormal breath sounds does not always signify improvement. As respiratory status worsens, there may be inadequate air movement to produce these sounds. In pediatric patients (especially infants), respiratory insufficiency may be the result of cardiac anatomical anomalies, in addition to standard causes. Peripheral cyanosis is a clue to this condition, and suspicion should be reported to accepting providers upon arrival.

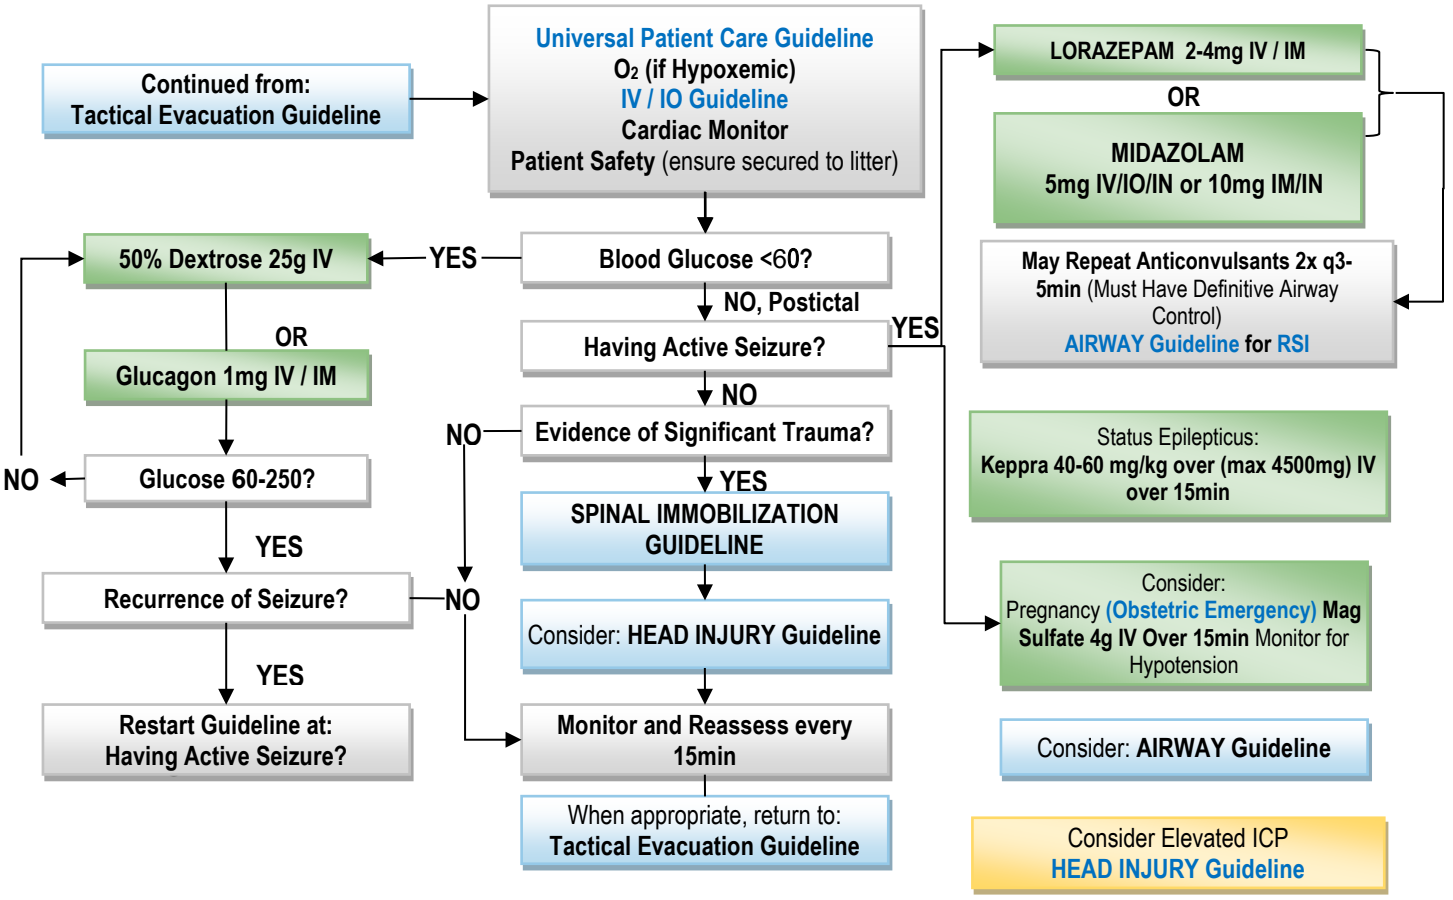
SEIZURE

Signs and Symptoms:

- **Decreased Mental Status**
- **Seizure Activity**
- **Somnolence**
- **Incontinence**
- **Evidence of Trauma**
- **Loss of Consciousness**
- **Oral Injuries (e.g., Tongue, Buccal)**

Differential Diagnosis:

- **CNS Trauma**
- **Tumor / Mass / Infection**
- **Metabolic**
- **Hypoxia**
- **Electrolyte Abnormality**
- **Drugs / Toxins**
- **Alcohol / Benzodiazepine Withdrawal**
- **Stroke**
- **Eclampsia**
- **Hyperthermia**
- **Hypoglycemia**



Pearls:

- Status epilepticus defined as seizure >15min or two or more continuous seizures without a period of consciousness / recovery. This is a real emergency requiring rapid airway control, treatment, and transport to the nearest suitable medical treatment facility.
- **Paralysis for airway control does not stop seizure activity** – only hides it. A seizure is a CNS electrical phenomenon and damage is still being done even when no muscular activity seen due to paralysis.
- Anticipate further seizure activity / recurrence and monitor continually.
- Assess probability of toxin, occult trauma, abuse, or substance use.
- Be prepared to assist with ventilations with the use of midazolam. If airway controlled and ventilating well – may give total of 4 doses of Midazolam.
- In **pregnant patients, Magnesium should be first line to abort non-epileptic seizures**. Midazolam should only be used if this fails (pregnancy class D).
- Adult Alcohol Withdrawal or Malnutrition **(Thiamine 100mg IV**).

Pediatric SEIZURE

Signs and Symptoms:

- **Decreased Mental Status**
- **Seizure Activity**
- **Somnolence**
- **Incontinence**
- **Evidence of Trauma**
- **Loss of Consciousness**
- **Oral Injuries (e.g., Tongue, Buccal)**

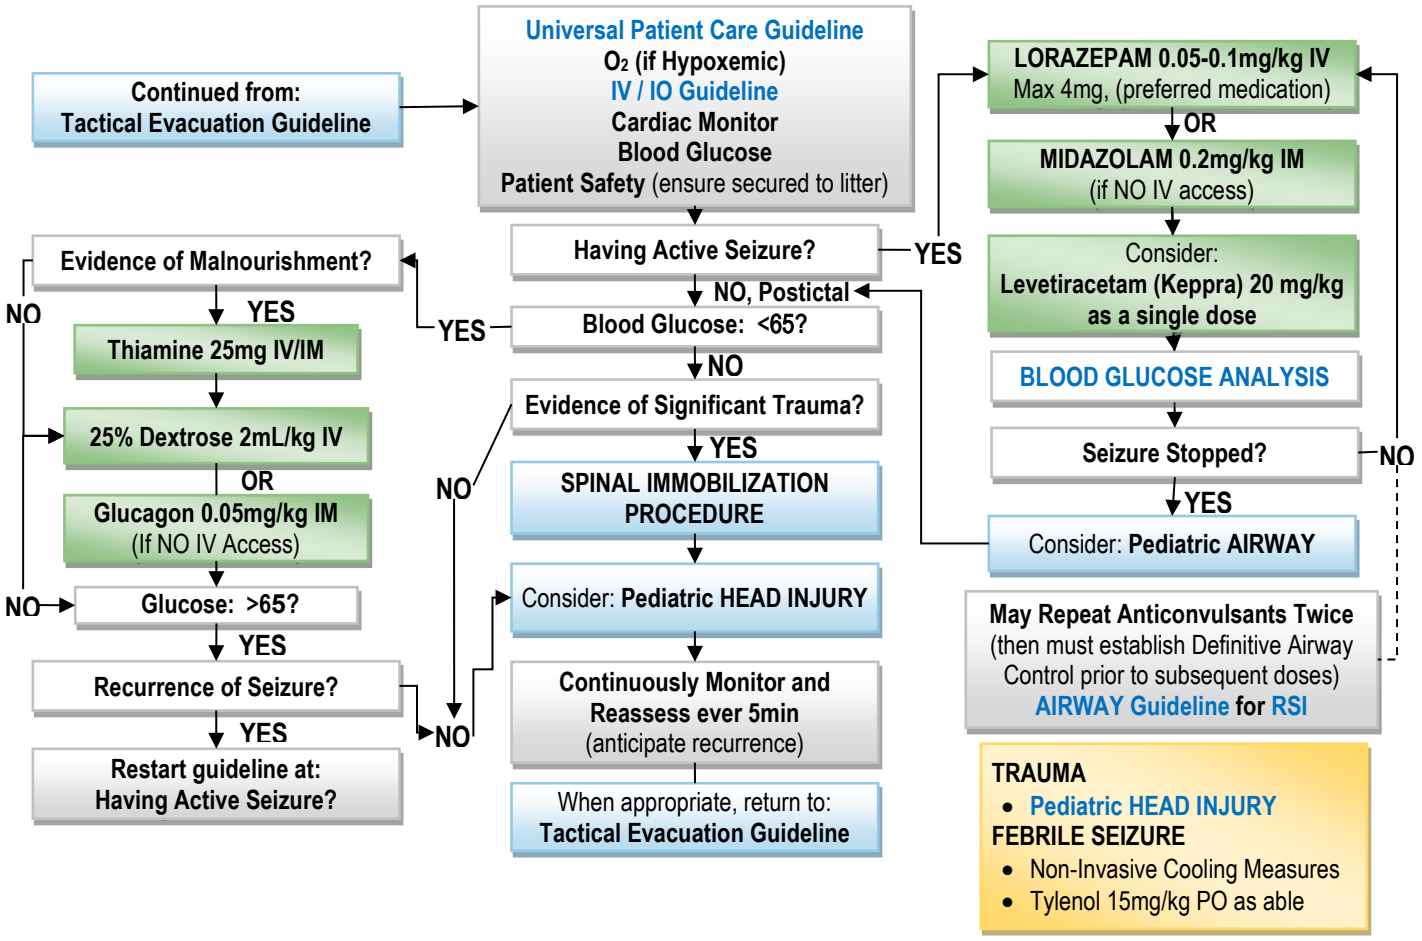
Differential Diagnosis by Age:

Less Than 3 Years Old:

- **Trauma**
- **Fever**
- **Infection**
- **Birth Injury**
- **Drug / Toxin**
- **Metabolic: Hypoglycemia / Electrolyte Abnormality**

More Than 3 Years Old:

- **Trauma, Infection, Brain Degenerative Disease**

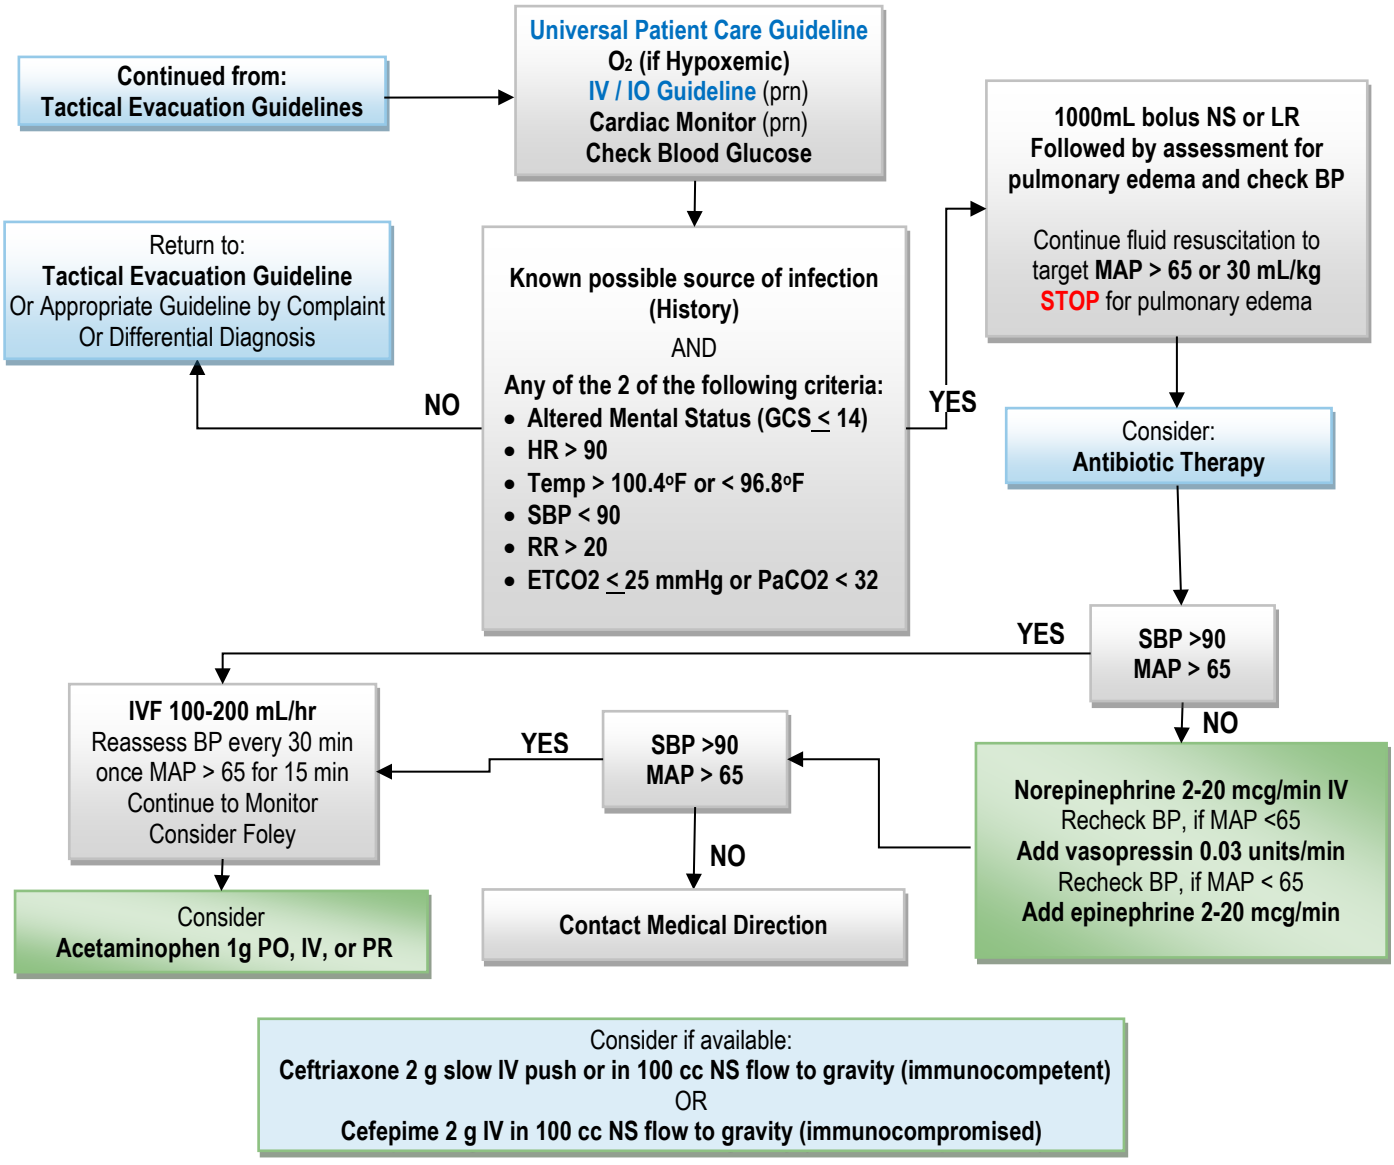


Pearls:

- Status epilepticus defined as seizure >5min or two or more successive seizures without a period of consciousness / recovery. This is a true emergency requiring rapid treatment and transport to nearest suitable medical treatment facility. Ensure adequate airway control is established if medication is administered.
- **Paralysis for airway control does not stop seizure activity** – only hides it. Seizure is a CNS electrical phenomenon and damage is still being done even when no muscular activity seen due to paralysis.
- **Be prepared to assist with ventilations** with the use of Lorazepam / Midazolam. If airway controlled and ventilating well – may give total of 4 doses of Lorazepam.
- MAX DOSES:
  - LORAZEPAM = 4mg/dose, D25 = 25mL/dose, GLUCAGON = 1mg/dose

SEPSIS

History	Signs and Symptoms	Differential Diagnosis:
• Fever • Previous infection • Recent surgery • Immunocompromised (transplant, HIV, diabetes, cancer, etc.) • Wound	• Altered Mental Status • Hyper or hypothermia • Chills • Myalgia • Rigors • Rash • Hyperglycemia • Decreased urine output	• Cardiogenic shock • Hypovolemic shock • CVA • MI • Acute renal failure • Hypoglycemia • Infection not meeting sepsis criteria



Consider if available:
Ceftriaxone 2 g slow IV push or in 100 cc NS flow to gravity (immunocompetent)
OR
Cefepime 2 g IV in 100 cc NS flow to gravity (immunocompromised)

Pearls:

- Early recognition of sepsis allows for attentive care, appropriate fluid resuscitation, vasoactive medications, and early administration of antibiotics.
- Utilize 6-8 mL/kg tidal volumes if artificially ventilated.
- Record urine output if foley in place. Decreased urine output is an indicator of patient deterioration.
- Use vasopressin despite less than maximal norepinephrine. Consider adding it when titrating above 8-10 mcg/min IV norepinephrine. Continue it once started and decrease norepinephrine to MAP goal.

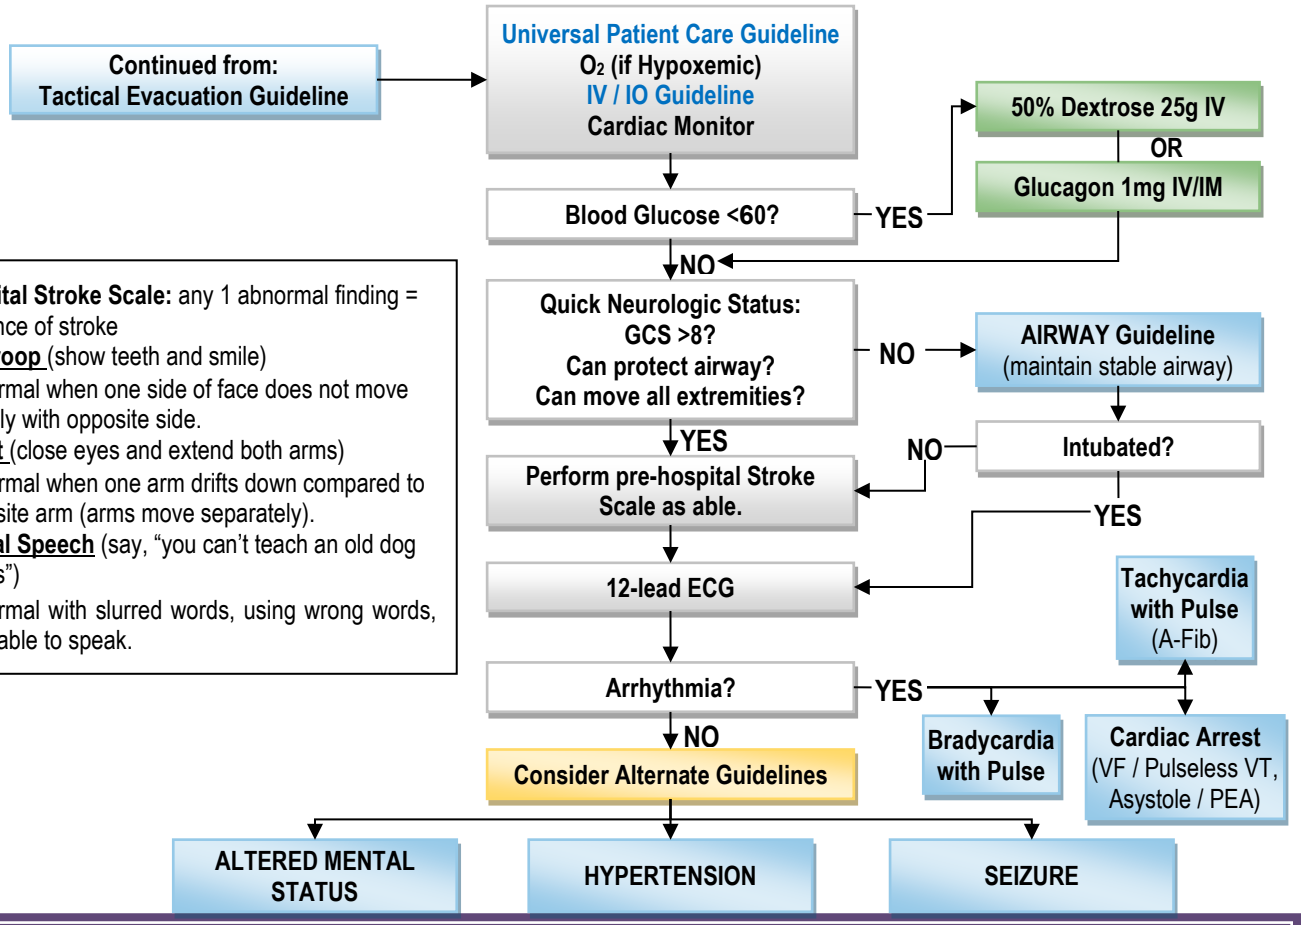
SUSPECTED STROKE / TIA

Signs and Symptoms:

- **Altered Mental Status**
- **Weakness / Paralysis**
- **Blindness or Other Sensory Loss**
- **Aphasia / Dysarthria**
- **Syncope**
- **Vertigo / Dizziness**
- **Vomiting**
- **Headache**
- **Seizures**

Differential Diagnosis:

- **Transient Ischemic Attack**
- **Stroke**
- **Seizure**
- **Hypoglycemia**
- **CNS Infection / Mass**
- **Trauma**
- **Metabolic**



Prehospital Stroke Scale: any 1 abnormal finding = 72% chance of stroke

Facial Droop (show teeth and smile)

- Abnormal when one side of face does not move equally with opposite side.

Arm Drift (close eyes and extend both arms)

- Abnormal when one arm drifts down compared to opposite arm (arms move separately).

Abnormal Speech (say, "you can't teach an old dog new tricks")

- Abnormal with slurred words, using wrong words, or unable to speak.

Pearls:

- Duration of symptoms should be determined as accurately as possible. Family members / colleagues can be helpful. If pt awaken with symptoms – onset time est. from last time patient was seen "normal."
- Be alert for airway problem / risk of aspiration. If concerned, request intubation before departure.
- Hypoglycemia can mimic stroke / TIA. May present with focal neurologic deficit, especially in the elderly.
- EKG should be obtained in all patients to evaluate for arrhythmia – especially atrial fibrillation.
- All TIAs should be transferred for evaluation, even if symptoms abated – these patients have a 10% risk of stroke within 30 days.
- **Aspirin should not be given to patients for suspected stroke.** Aspirin use is a contraindication to the use of thrombolytics for stroke.
- All strokes/TIAs are not associated with motor findings. Although uncommon, pure sensory strokes can occur. More frequently, very subtle motor abnormalities are present that the patient may not note.
- **Systolic greater than 185 or Diastolic greater than 110**: give Labetalol **10-20 mg IV for 1-2 minutes**. May repeat 1 time.
- **Aim for no more than a 20% reduction in MAP. MAP = [(2 x Diastolic) + Systolic] / 3** For additional info see: ALS Acute Coronary Syndromes and Stroke.

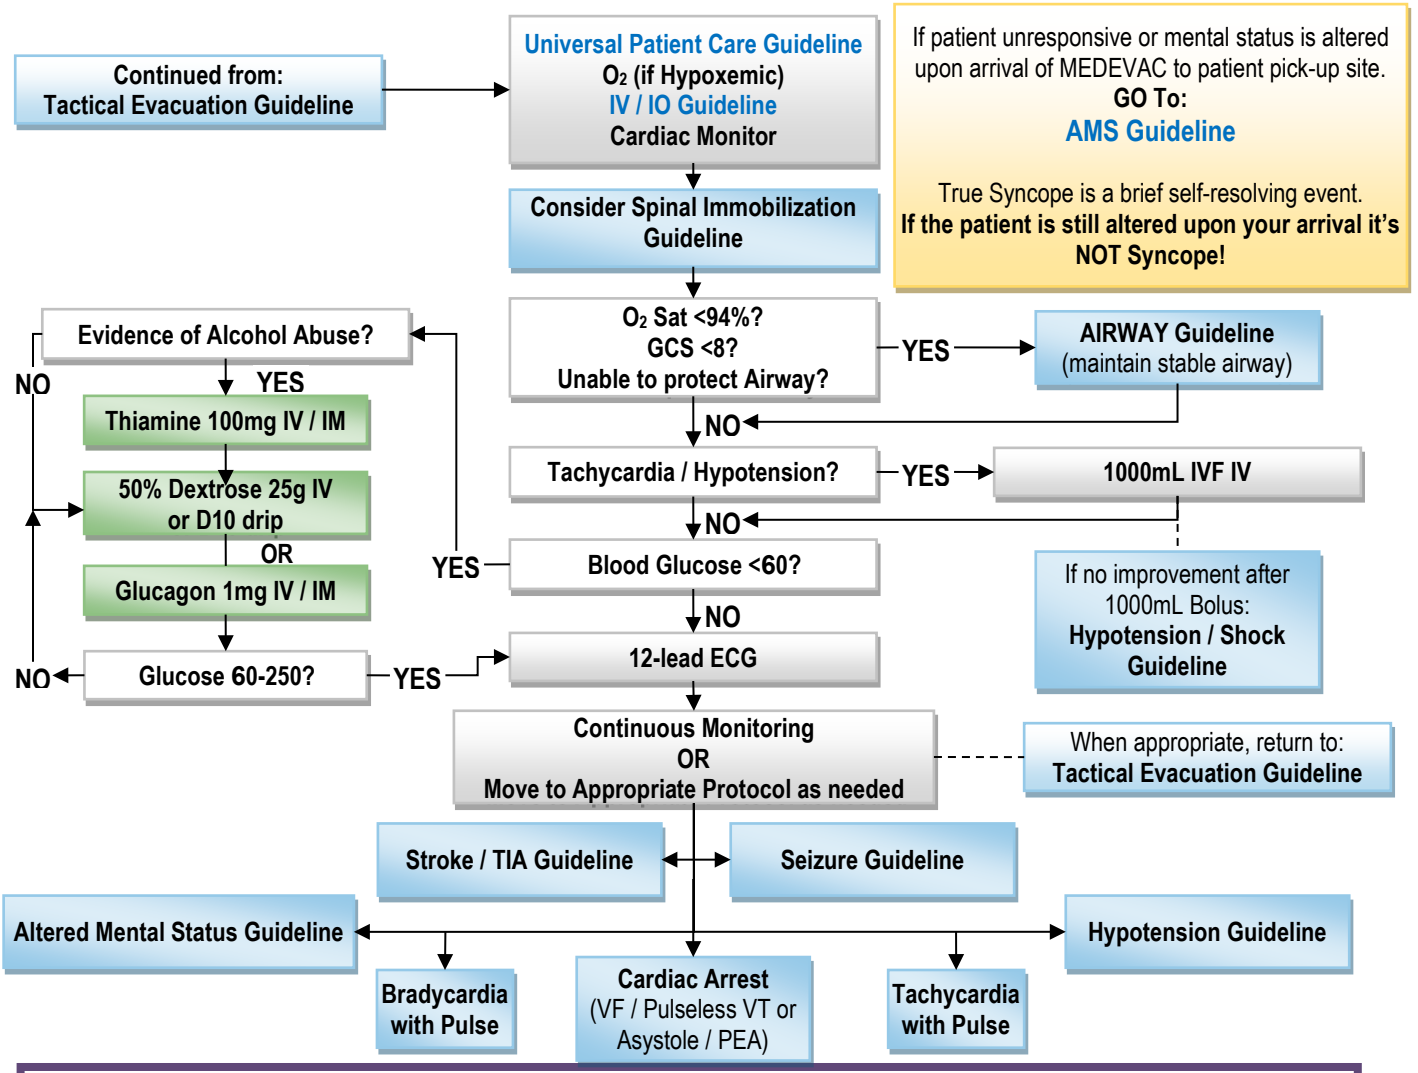
SYNCOPE

Signs and Symptoms:

- Loss of Consciousness with Recovery
- Lightheadedness / Dizziness
- Nausea / Vomiting
- Palpitations / Chest Pain
- Shortness of Breath
- Decreased Pulse Pressure

Differential Diagnosis:

- Vasovagal Episode
- Orthostatic Hypotension
- Cardiac Etiology
- Psychiatric
- Stroke
- Hypoglycemia
- Seizure
- Shock
- Toxicologic / Medication



Pearls:

- Assess every patient for signs of trauma if suspected with syncopal event.
- Consider occult bleeding in all cases of syncope: GI bleeding, ruptured ectopic pregnancy, and seizure.
- Prodromal symptoms (e.g., flushing, lightheadedness, diaphoresis, tunnel vision) are often associated with more innocent etiologies, especially if temporally related to standing / rising. Absence of prodrome should raise concern for cardiac / CNS (emergent) etiologies.
- It is uncommon for stroke to cause syncopal episode.
- Patients who sustain trauma to the temporal region of the skull and are now lucid may experience a precipitous loss of consciousness / degeneration due to epidural hematoma.

TOXIC INGESTIONS

Signs and Symptoms:
- **Mental Status Changes**
- **Hypo / Hypertension**
- **Respiratory Depression**
- **Tachycardia / Arrhythmias**
- **Seizure**

Differential Diagnosis:
- **Cyclic Antidepressants**
- **Acetaminophen**
- **Depressants**
- **Stimulants**
- **Anticholinergic**
- **Cardiac Medications**
- **Solvents / Cleaners**
- **Organophosphate / Carbamate**
- **Medical Cause (hyperthyroidism)**

Continued from: Tactical Evacuation Guideline

Universal Patient Care Guideline
O_2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)

If possible,
Contact Poison Control Center or Medical Control if toxin known or for treatment advice
In US: 1-800-222-1222

Supportive care is keystone in management of toxic ingestions:
- Continuous monitoring, supplemental O_2 / airway support, IVF resuscitation

Blood Sugar <60?
- YES → **Altered Mental Status Guideline** (50% Dextrose 25g in 500mL NS IV or Glucagon 1mg IM if no IV)
- NO → **IV Bolus PRN**

TriCyclic Overdose:
QRS >100 = Predictive of seizures
QRS >160 = Predictive of VT

Activated Charcoal 1gram/kg PO (If alert / protecting airway and time of ingestion <1hr)

Beta Blocker Overdose:
AV Block (especially, 1st Degree), Bradycardia, and Hypotension:
Consider giving: Glucagon 3-10mg IV / IM Bolus followed by 3-5mg/hr infusion

Opiates (Respiratory Depression)
- **Naloxone 0.4-2mg IV / IO**
- **Airway Guideline**

TriCyclic Antidepressant
- **12 Lead EKG**
- **QRS >100ms or Hypotensive?**
- **Sodium Bicarbonate 1mEq/kg**
  May repeat to maintain QRS <100
  Start Maintenance Infusion:
  100-150mEq (2-3 amps) in 1 L D5 / NS @ 100-200 mL/hr IV

Organophosphate / Carbamate
- **Atropine 2mg IV / IO q5min** (No max dose: give until improving with ↓ secretions)
- **2-PAM 600mg IV / IM** (Atropine + 2-PAM = Mark 1 Kit)
- **If in Seizure give:**
- **Midazolam 2.5-5mg IV/IM x 2**
- **Seizure Guideline**

Other
- **12-lead EKG**
- **Hypotension, Seizures, Ventricular Dysrhythmias, Altered Mental Status, Chest Pain**
- **Appropriate Guideline**

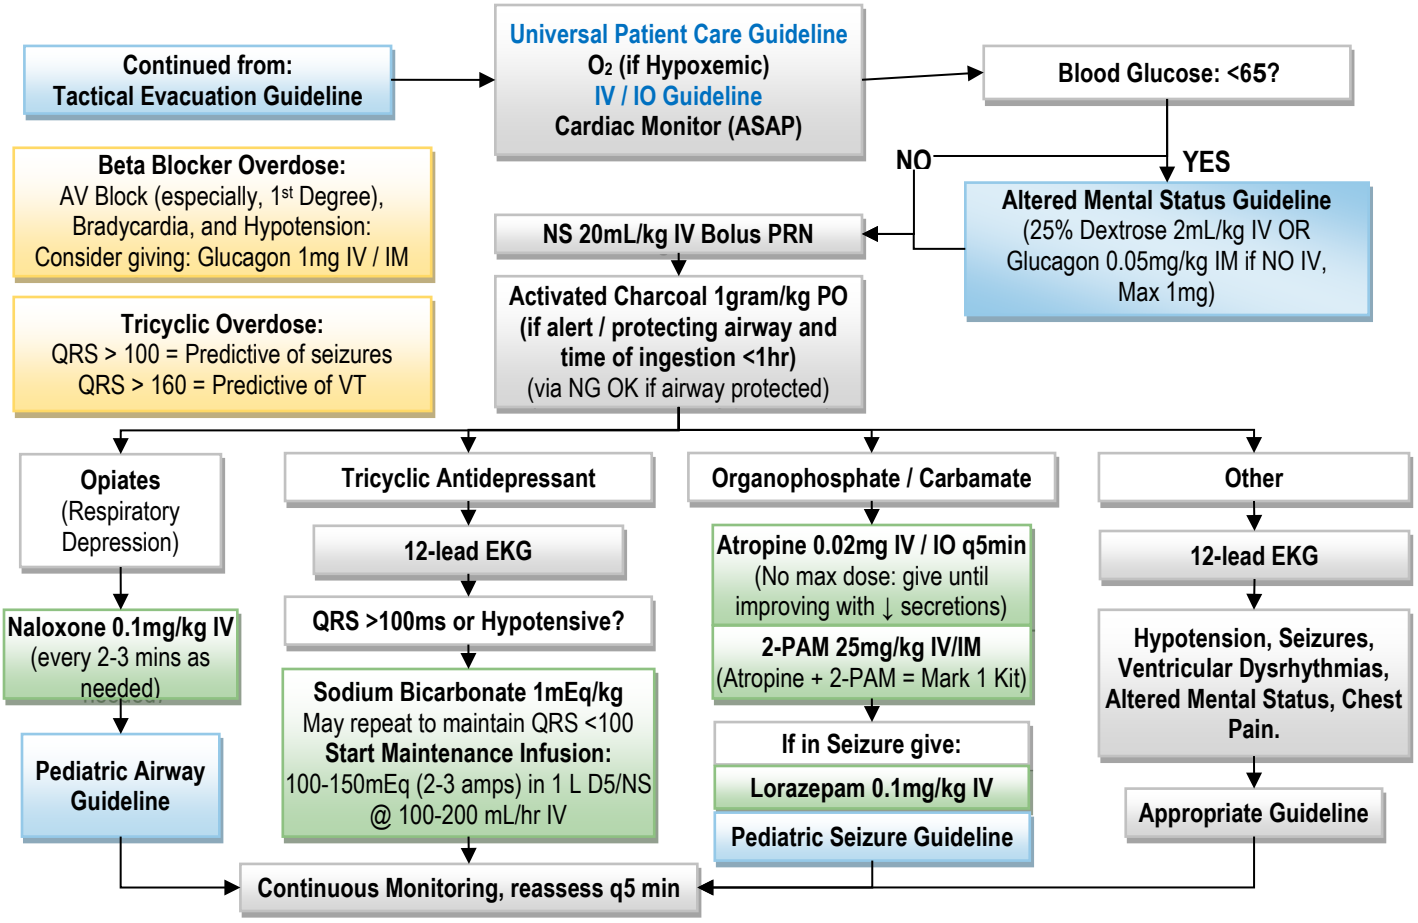
Continuous Monitoring, reassess q5 min

Pearls:
- **Anticholinergic**: Altered mental status (mad as a hatter), Hyperthermia (hot as a hare), mydriasis (blind as a bat), Flushing (red as a beet), anhidrosis (dry as a bone), Full Bladder (full as a flask).
  - Treat as with Tricyclic overdose pathway (including EKG and Sodium Bicarb for prolonged QRS and/or arrhythmias)
  - LORAZEPAM for agitation and seizures and Hyperthermia Guideline if hyperthermic
- **Beta Blocker**: Hypoglycemia.
- **Calcium Channel Blocker:** HypERglycemia.
- **Cyclic Antidepressant:** Hypotension, depressed mental status, respiratory depression, cardiac arrhythmias.
- **Opioid:** Depressed mental status, pinpoint pupils, N/V, respiratory depression, hypotension possible.
- **Organophosphate / Carbamate (Cholinergic):** Salivation, lacrimation, urination, diarrhea, emesis, altered mental status.
- **Sympathomimetic / Stimulant (Methamphetamine / Cocaine)**: Altered mental status, tachycardia, diaphoresis, mydriasis, and hyperthermia. Treat with Benzodiazepine (LORAZEPAM) and PRN cooling or Hyperthermia Guideline.

Pediatric TOXIC INGESTIONS

Signs and Symptoms:
- **Mental Status Changes**
- **Hypo / Hypertension**
- **Respiratory Depression**
- **Tachycardia / Arrhythmias**
- **Seizure**

Differential Diagnosis:
- **Cyclic Antidepressants**
- **Acetaminophen**
- **Depressants**
- **Stimulants**
- **Anticholinergic**
- **Cardiac Medications**
- **Solvents / Cleaners**
- **Organophosphates / Carbamate**
- **Medical Cause (hyperthyroidism)**



Pearls:
- **Anticholinergic**: Altered mental status (mad as a hatter), hyperthermia (hot as a hare), mydriasis (blind as a bat), Flushing (red as a beet), anhidrosis (dry as a bone), Full Bladder (full as a flask).
  - Treat as with Tricyclic overdose pathway (including EKG and Sodium Bicarb for prolonged QRS and/or arrhythmias)
  - LORAZEPAM for agitation and seizures and Hyperthermia Guideline if hyperthermic.
- **Beta Blocker**: HypOglycemia.
- **Calcium Channel Blocker:** HypERglycemia.
- **Cyclic Antidepressant:** Hypotension, depressed mental status, respiratory depression, cardiac arrhythmias.
- **Opioid:** Depressed mental status, pinpoint pupils, N/V, respiratory depression, hypotension possible.
- **Organophosphate / Carbamate (cholinergic):** Salivation, lacrimation, urination, diarrhea, emesis, altered mental status.
- **Sympathomimetic / Stimulant (Methamphetamine / Cocaine)**: Altered mental status, tachycardia, diaphoresis, mydriasis, and hyperthermia. Treat with Benzodiazepine (LORAZEPAM) and PRN cooling or Hyperthermia Guideline.

VOMITING & DIARRHEA

Signs and Symptoms:

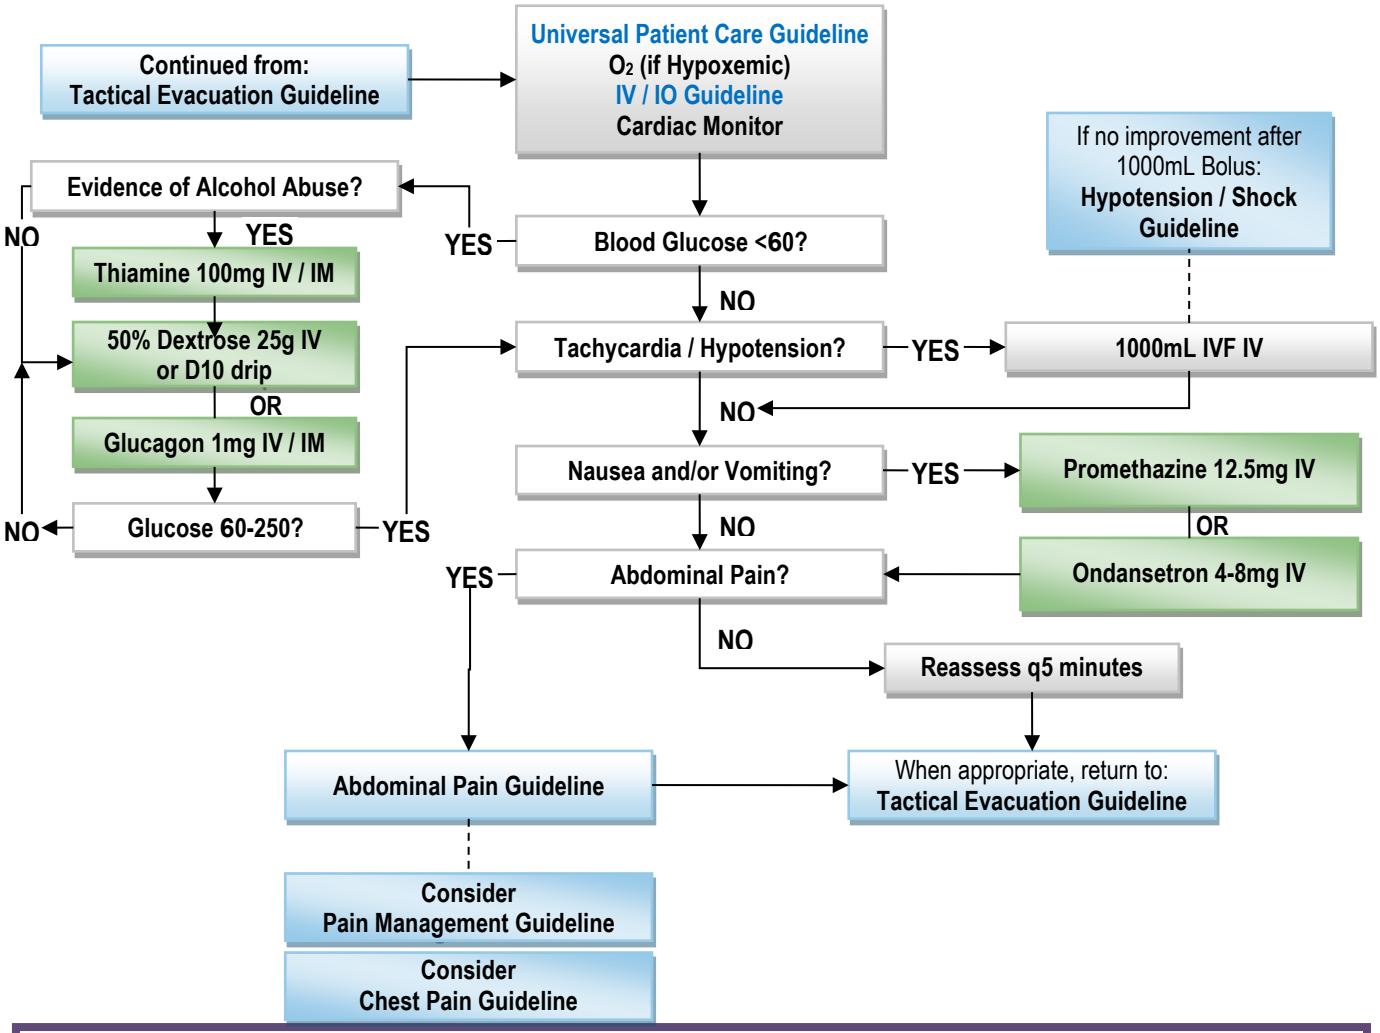
- Pain
- Abdominal Distention
- Constipation
- Diarrhea
- Anorexia

Associated Symptoms:

Fever, Headache, Weakness, Malaise, Myalgia, Cough, Dysuria, Mental Status Changes, Rash

Differential Diagnosis:

- CNS Injury / Mass / Infection
- Myocardial Infarction
- Drugs / Toxins
- Bowel Obstruction
- Diabetic Ketoacidosis
- Pregnancy
- Infections
- Gastroenteritis
- Food Borne / Toxic
- Psychologic
- Appendicitis



Pearls:

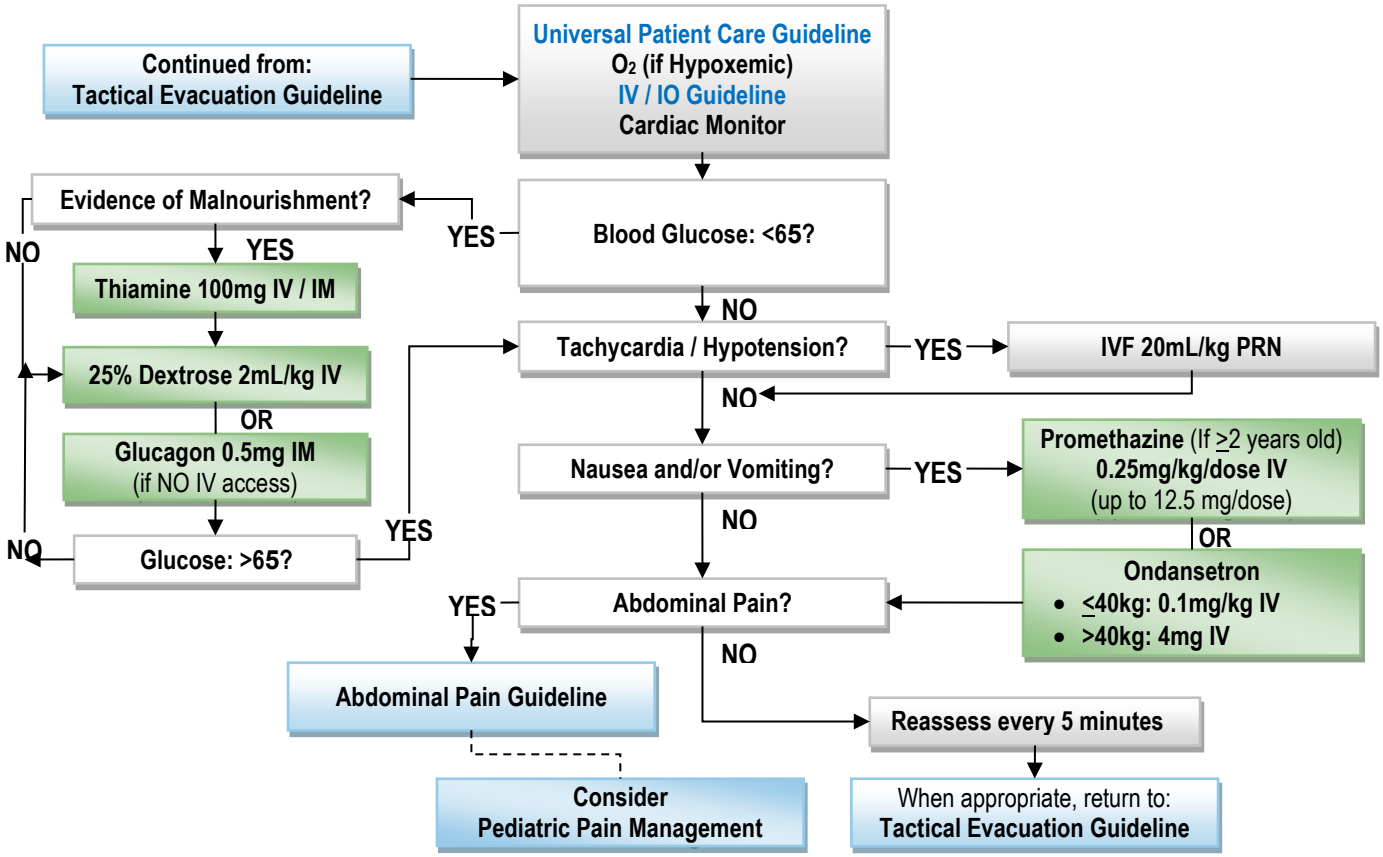
- Suspicion of other underlying condition should prompt immediate referral to appropriate protocol.
- In pregnant patients with nausea / vomiting – can substitute D5 1/2NS or D5NS in place of NS.
- Fluid of choice for vomiting is NS. Fluid of choice for diarrhea is LR.
- Continually monitor for any decompensation.

Pediatric VOMITING & DIARRHEA

Signs and Symptoms:
- Pain
- Abdominal Distention
- Constipation
- Diarrhea
- Anorexia

Associated Symptoms:
Fever, Headache, Weakness, Malaise, Myalgia, Cough, Dysuria, Mental Status Changes, Rash

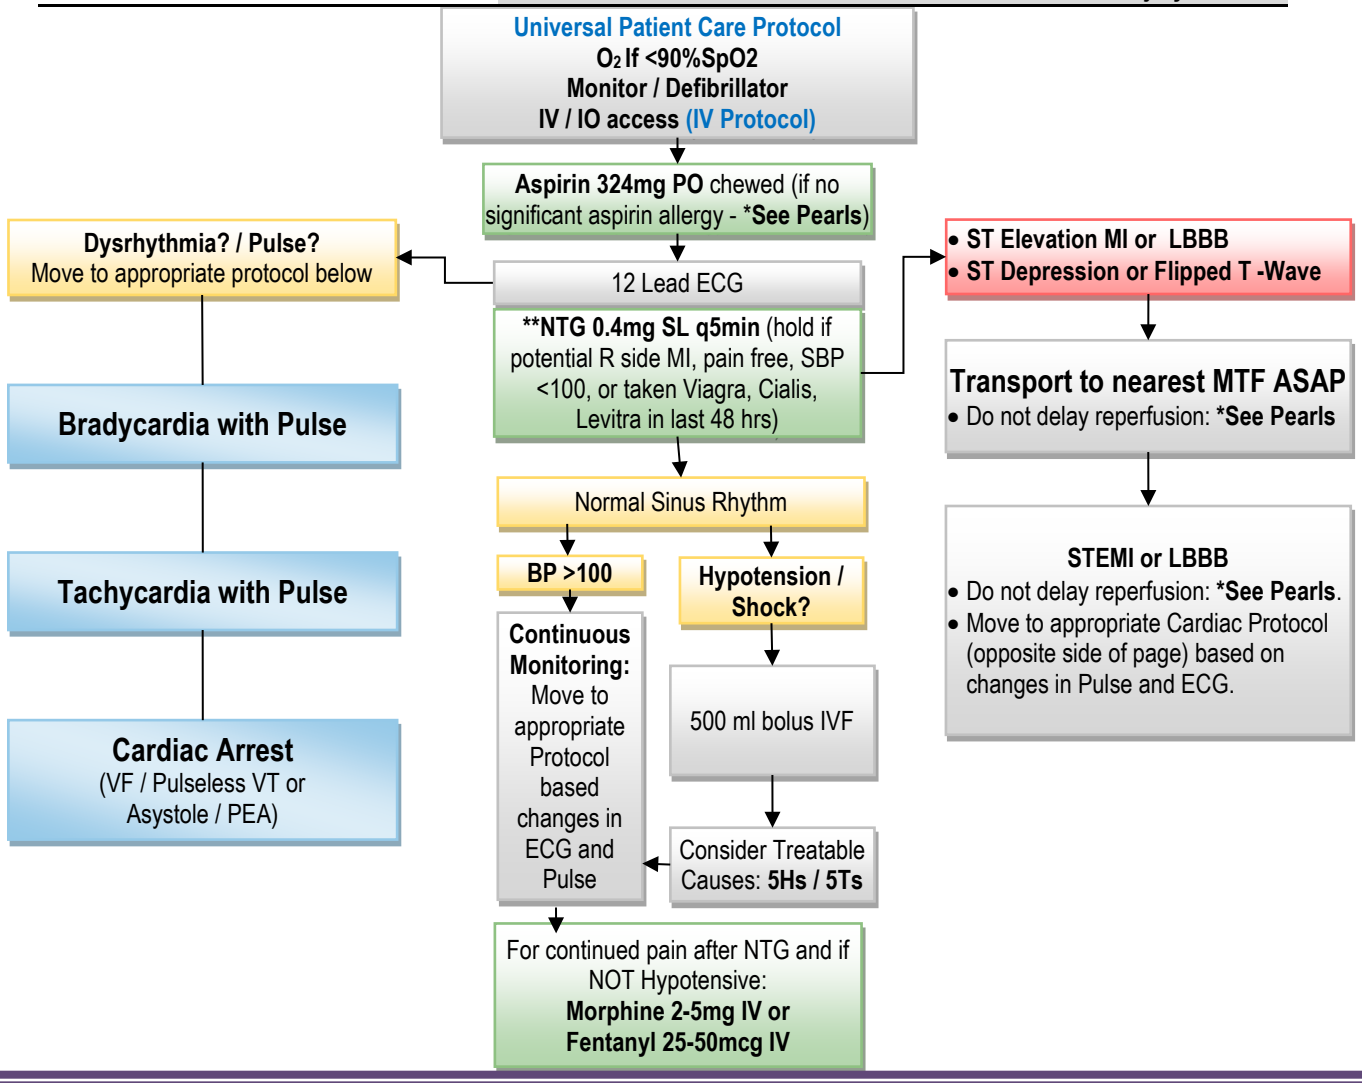
Differential Diagnosis:
- CNS Injury / Mass / Infection
- Myocardial Infarction
- Drugs / Toxins
- Bowel Obstruction
- Diabetic Ketoacidosis
- Pregnancy
- Infections
- Gastroenteritis
- Food Borne / Toxic
- Psychologic
- Appendicitis



Pearls:
- Suspicion of other underlying condition should prompt immediate referral to appropriate guideline.
- Continually monitor for any decompensation.

CHEST PAIN

Signs and Symptoms:	Differential Diagnosis:	Differential Diagnosis:
• **Chest Pain** • **Radiation of Pain** • **Location of Pain** • **Pale / Diaphoretic / Lightheaded** • **Nausea / Vomiting** • **Shortness of Breath**	• **Angina** • **Acute MI** • **Pericarditis** • **Pulmonary Embolism** • **Asthma / COPD** • **Pneumothorax**	• **Aortic Dissection / Aneurysm** • **GERD** • **Esophageal Spasm** • **Esophageal perforation** • **Chest Wall Injury / Pain**

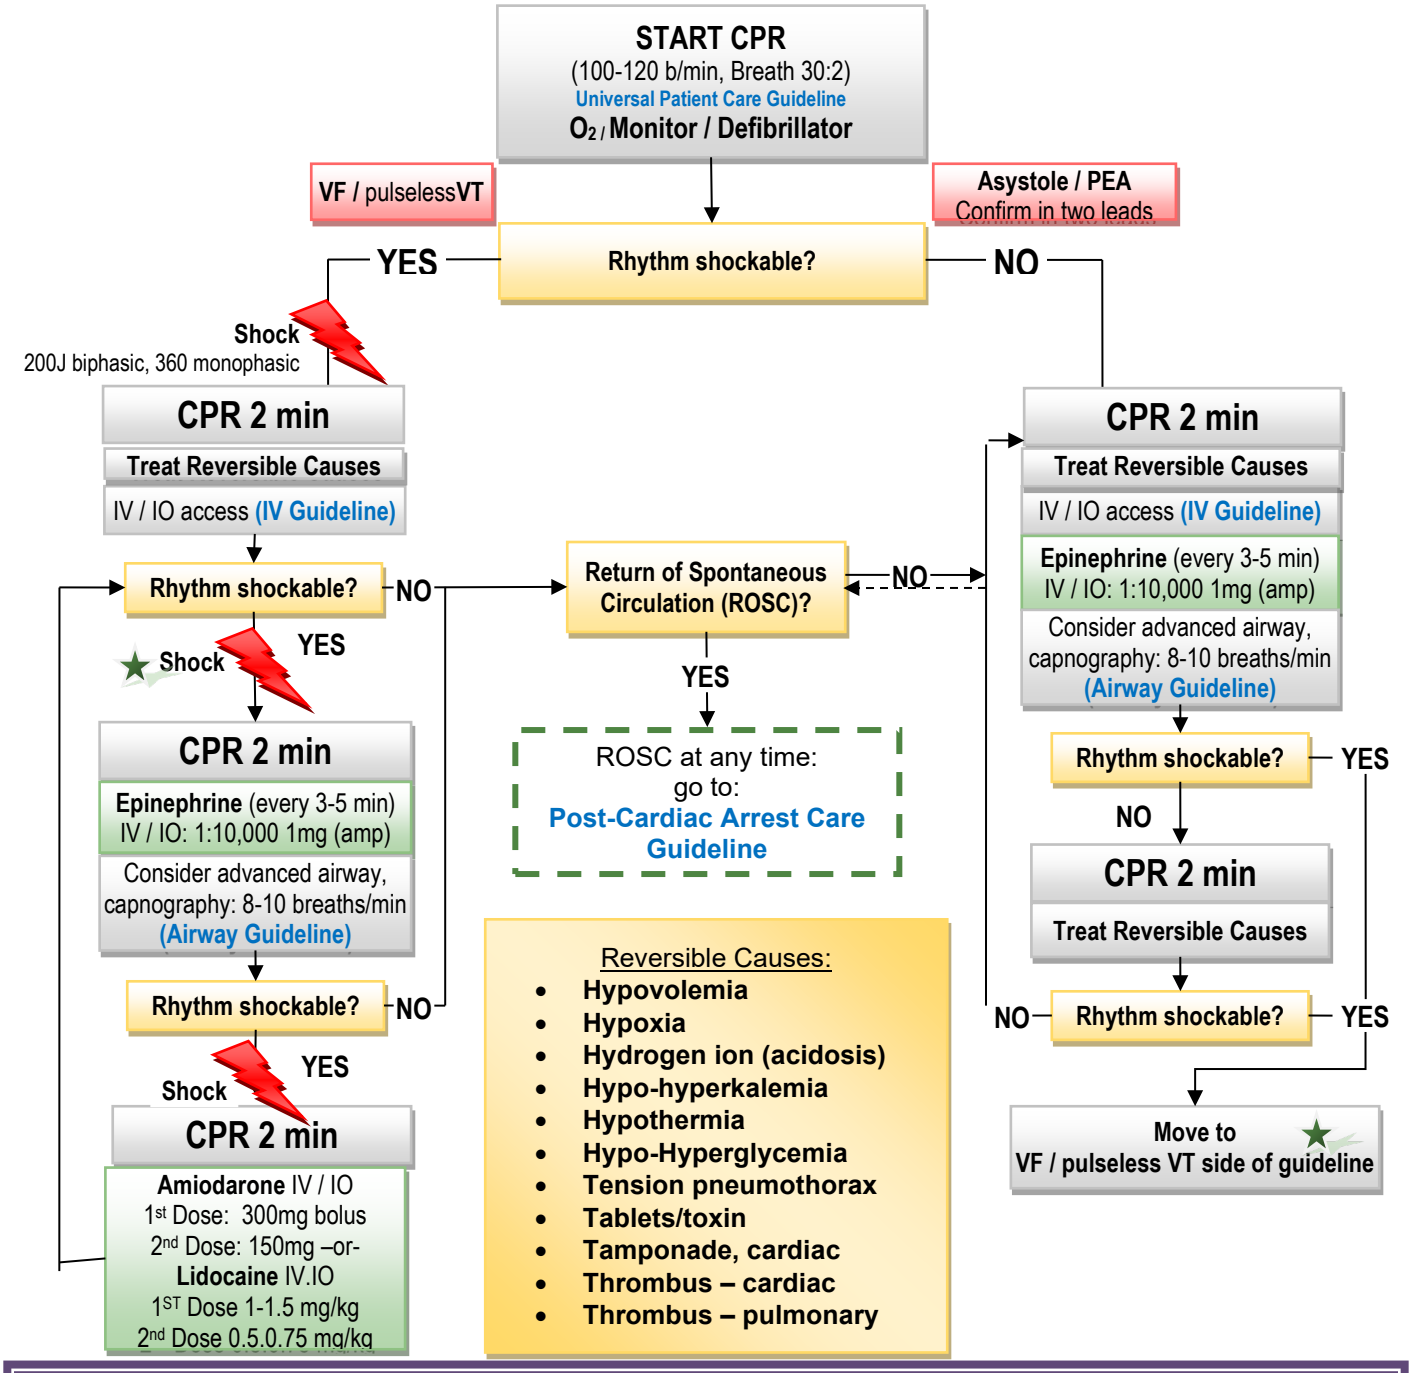


Universal Patient Care Protocol
O2 If <90%SpO2
Monitor / Defibrillator
IV / IO access (IV Protocol)
Aspirin 324mg PO chewed (if no significant aspirin allergy - *See Pearls)
12 Lead ECG
**NTG 0.4mg SL q5min (hold if potential R side MI, pain free, SBP <100, or taken Viagra, Cialis, Levitra in last 48 hrs)
Normal Sinus Rhythm
BP >100
Hypotension / Shock?
500 ml bolus IVF
Consider Treatable Causes: 5Hs / 5Ts
Continuous Monitoring: Move to appropriate Protocol based changes in ECG and Pulse
For continued pain after NTG and if NOT Hypotensive:
Morphine 2-5mg IV or
Fentanyl 25-50mcg IV
Dysrhythmia? / Pulse?
Move to appropriate protocol below
Bradycardia with Pulse
Tachycardia with Pulse
Cardiac Arrest
(VF / Pulseless VT or Asystole / PEA)
• ST Elevation MI or LBBB
• ST Depression or Flipped T -Wave
Transport to nearest MTF ASAP
• Do not delay reperfusion: *See Pearls
STEMI or LBBB
• Do not delay reperfusion: *See Pearls.
• Move to appropriate Cardiac Protocol (opposite side of page) based on changes in Pulse and ECG.

Pearls:

- **Aspirin** should be held only for patients with known significant allergy.
- Patients with suspected AMI should be transferred to the nearest MTF for further treatment / thrombolytics.
- **With right sided MI (ST Elevations in leads II, III, AvF), NTG may cause hypotension so use with caution. Add small fluid boluses for low BP.
- Ensure that you have IV access before giving SL NTG.
- **Hold Morphine or Fentanyl for SBP <90**.
- Max dose Morphine 20mg, Fentanyl 200mcg for non-traumatic chest pain (higher doses may be required for trauma, see Pain Control algorithm).

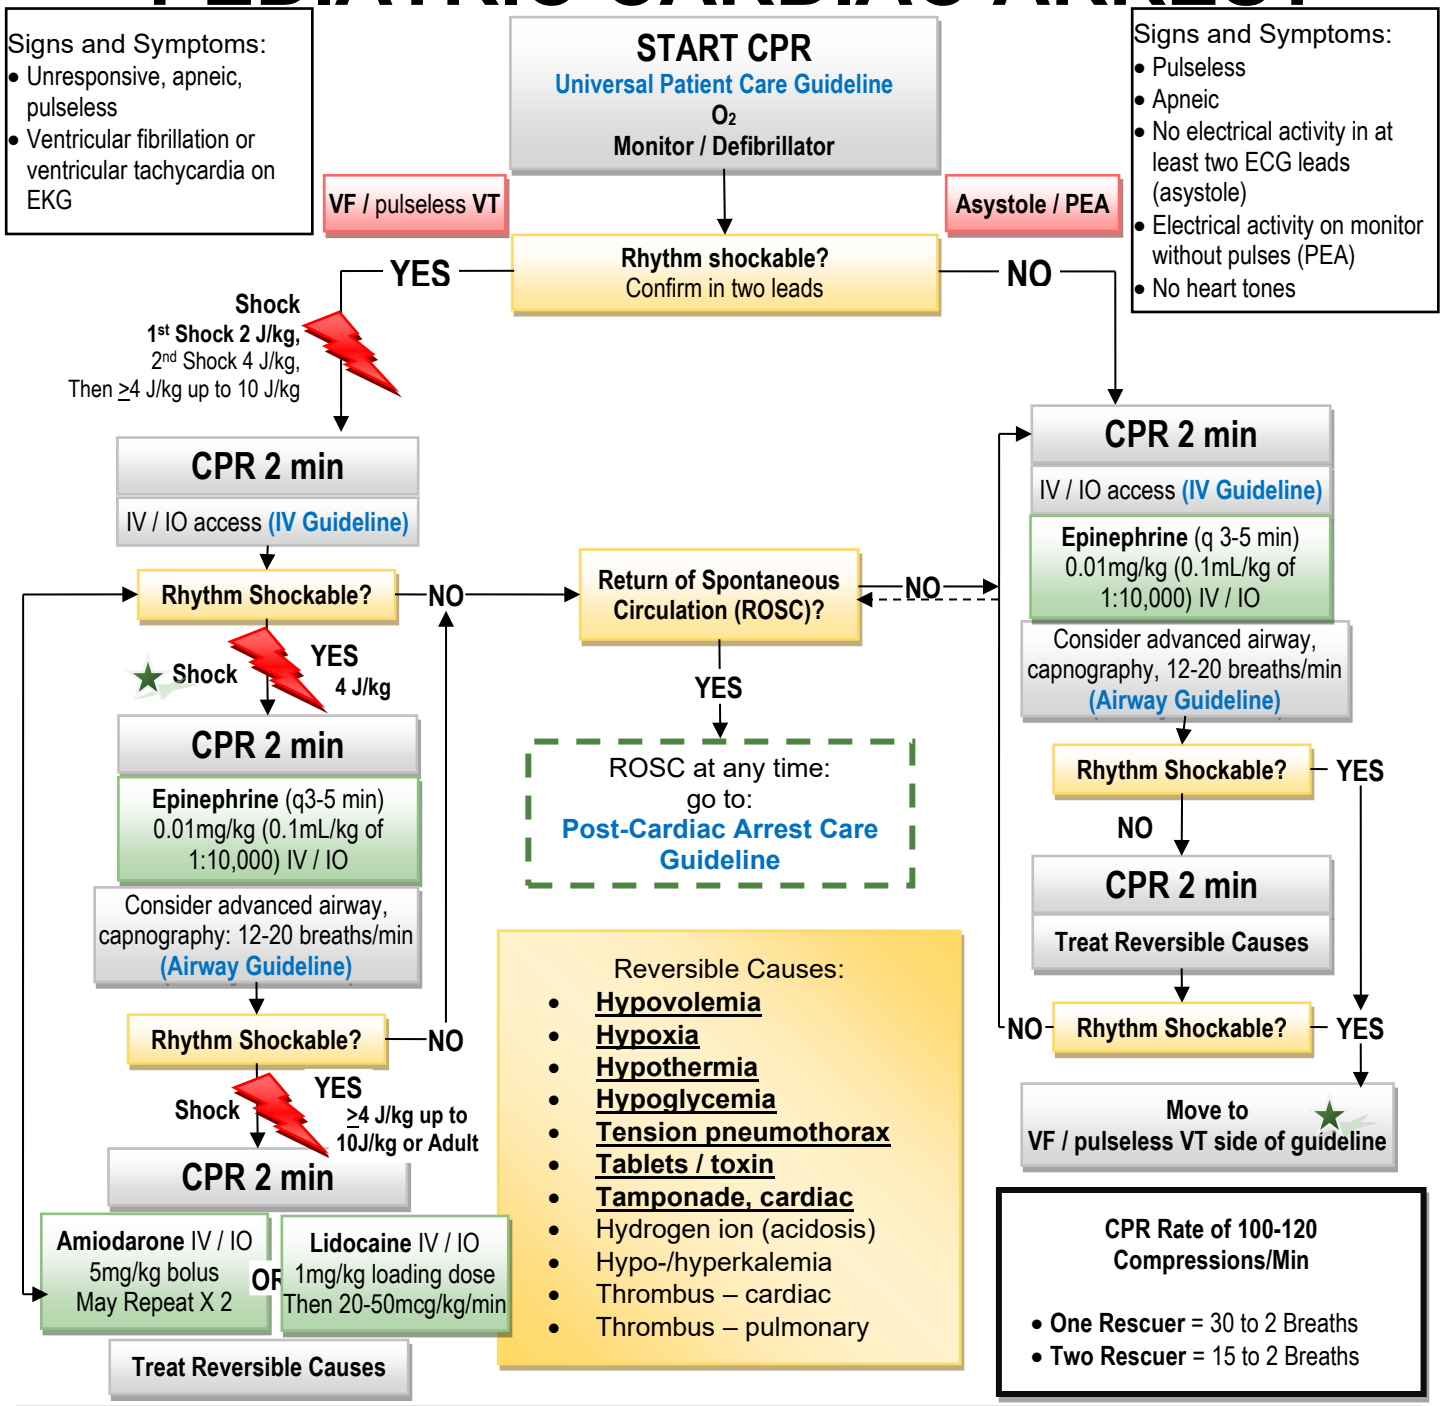
CARDIAC ARREST



Pearls:

- Reversible causes should be addressed as soon as possible.
- Consider discontinuation of efforts if:
  - Asystole following trauma – especially blunt.
  - Prolonged downtimes - > 15min.
  - Prolonged code with no response - >3 rounds of medications, 30min of resuscitation.
  - **All patients should get a glucose check, at least 1L fluid bolus, and ultimately bilateral needle decompression (especially in Trauma) before discontinuation of efforts.**
  - Should take at least 1min to check for pulse in hypothermic patients.

PEDIATRIC CARDIAC ARREST



Pearls:

- **CPR Rate of 100-120 / Min 2 inches depth for children and 1 1/2 inches depth for infants of chest with complete chest recoil**
  - Reversible causes should be addressed as soon as possible.
  - Epinephrine Endotracheal Dose: 0.1 mg/kg (0.1mL/kg of 1:1,000 vial)
  - Consider discontinuation of efforts if:
    - Asystole following trauma – especially blunt
    - Prolonged downtimes - > 15min
    - Prolonged code with no response - >3 rounds of medications, 30min of resuscitation
    - **All patients should get a glucose check, at least 20ml/kg fluid bolus of NS, and ultimately bilateral needle decompression (Trauma) before discontinuation of efforts**

PEDIATRIC ALS and BLS INDICATORS

Indicators of Potential Need for Cardiopulmonary Support

- **Breathing**
  - Irregular Respirations or >60 breaths/min
  - Labored Breathing (Retractions, Nasal Flaring, Grunting, Pursing of Lips, Tripod Positioning, ↓Ability to Speak)
- **Heart Rate Ranges** (especially if associated with poor perfusion)
  - ≤2 Years Old: <80/min or >180/min
  - >2 Years Old: <60/min or >160/min
- **Poor Perfusion with Weak or Absent Distal Pulses**
  - Cyanosis
  - ↓O_2 Sat
- **Altered Mental Status**
  - GCS <8, Weak Cry, Unusual Irritability, Altered Responsiveness, Lethargy, or Failure to Respond to Painful Stimulus
- **Seizures, Fever with Petechiae, Trauma, and/or Burns >10% Body Surface Area**

IOT Prevent Cardiac Arrest You Must Detect and Treat:
Respiratory Failure / Respiratory Arrest / Shock
Pediatric Cardiac Arrest Results from Deterioration in Respiratory or Cardiac Function!

Heart Rate/Min

Age	Awake Rate	Mean	Sleeping Rate
Newborn to 3mo	85-205	140	80-160
3mo - 2y	100-190	130	75-160
2 - 10y	60-140	80	60-90
>10y	60-100	75	50-90

Respiratory Rate/Min

Age	Rate
Infant	30-60
Toddler	24-40
Preschool	22-34
School	18-30
Adolescent	12-16

Blood Pressure	Average	Lower Limit
1-10y	90+(years old x 2)mmHg	70+(years old x 2)mmHg
>10y		90mmHg
MAP	55+(years old x 1.5)mmHg	

Rescue Breathing Ventilation Rate Without Advanced Airway:
- **NEWBORN** = 40-60/min when performed without compressions
- **Infant / Child** = 1 breath / 3 to 5 seconds

CPR Rate of 100 Compressions / Min at:
- **One Rescuer** = 30 Compressions and 2 Breaths
- **Two Rescuer** = 15 Compressions and 2 Breaths

Universal Patient Care
O_2 (100% FiO_2)
Monitor / Defibrillator
IV / IO access (IV Protocol)

Unresponsive, Not Breathing or ALS Indicators

Check Pulse (up to 10 sec)

DEFINITE Pulse
- GIVE: 1 Breath every 3-5 seconds
- Ensure adequate oxygenation & ventilations
- Recheck Pulse every 2 minutes
  - Add compressions if pulse <60/min despite O_2 and Ventilation
  - Move to appropriate Guideline

Rapid Pulse with good perfusion?
→ **PEDs Tachycardia with Pulse & Adequate Perfusion**

Rapid Pulse with poor perfusion despite O_2 and ventilation?
→ **PEDs Tachycardia with Pulse & Poor Perfusion**

Pulse <60/min with poor perfusion despite O_2 and ventilation?
→ **Begin CPR and move to appropriate protocol**
→ **PEDs Bradycardia with Pulse & Poor Perfusion**

No Pulse?
→ **Begin CPR and move to appropriate protocol**
→ **Pediatric Cardiac Arrest**

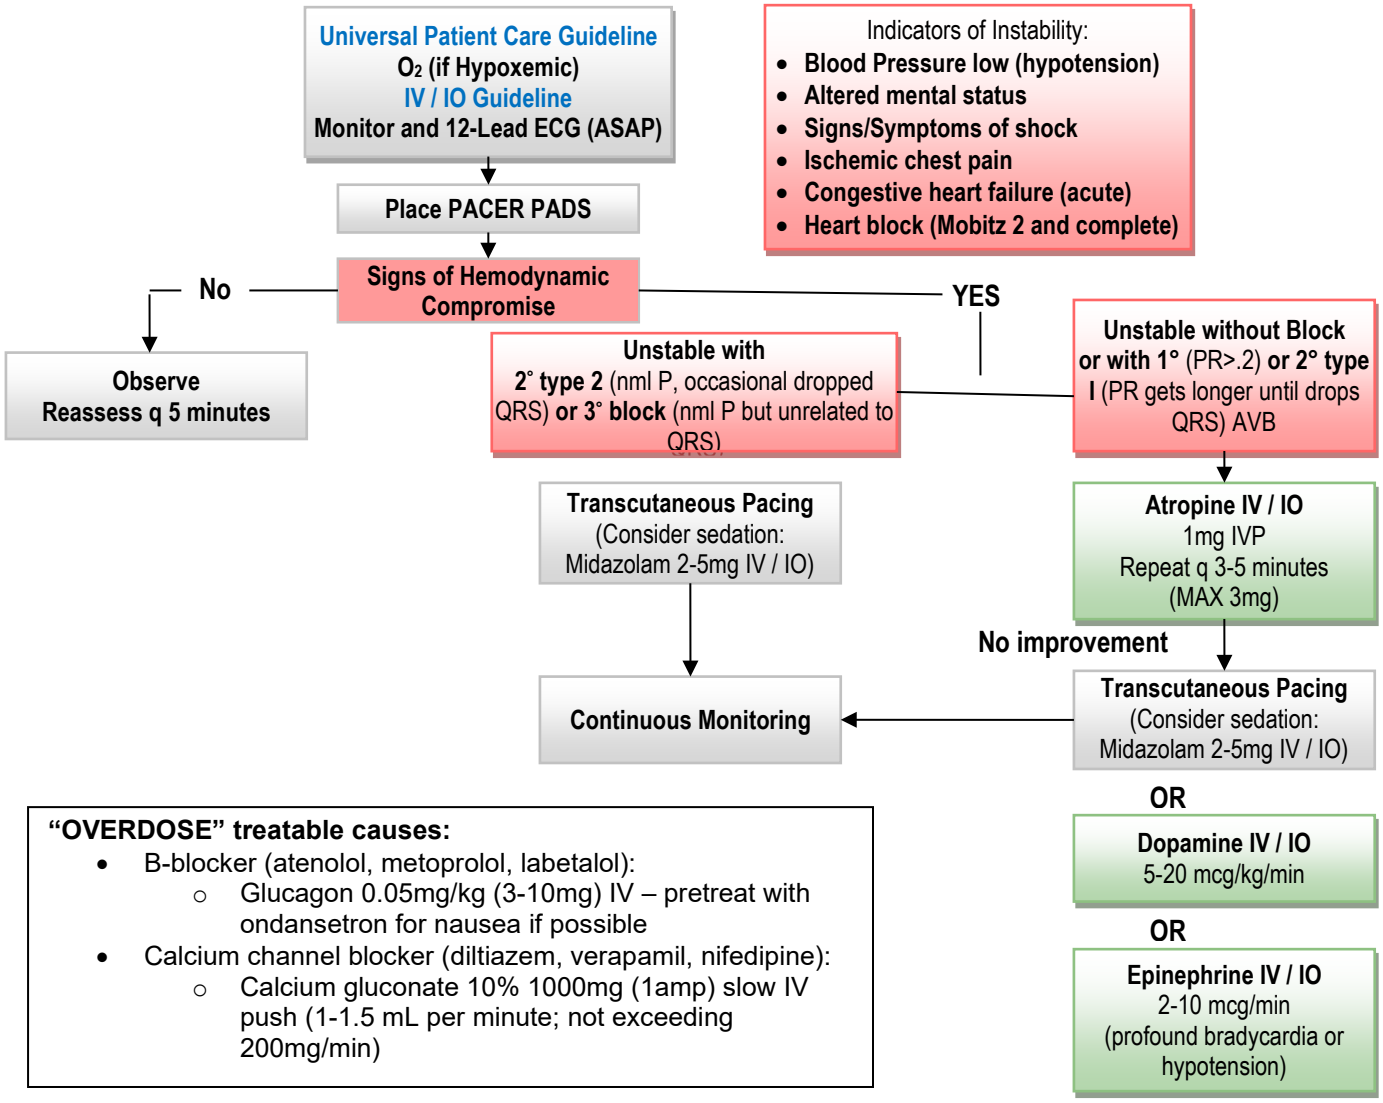
BRADYCARDIA with PULSE

Signs and Symptoms:

- HR <50bpm
- Chest Pain
- Respiratory Distress
- Hypotension / Shock
- Altered Mentation
- Syncope

Differential Diagnosis:

- Acute MI
- Hypoxia
- Hypothermia
- Sinus Bradycardia
- Physiologic Bradycardia (Athletes)
- Stroke
- Spinal Cord Lesion
- Toxin / Medications (B-blockers)
- AV Block / Sick Sinus Syndrome



"OVERDOSE" treatable causes:

- B-blocker (atenolol, metoprolol, labetalol):
  - Glucagon 0.05mg/kg (3-10mg) IV – pretreat with ondansetron for nausea if possible
- Calcium channel blocker (diltiazem, verapamil, nifedipine):
  - Calcium gluconate 10% 1000mg (1amp) slow IV push (1-1.5 mL per minute; not exceeding 200mg/min)

Pearls:

- Decompensation at any time (e.g., altered MS, hypotension) should prompt treatment as unstable patient.
- All bradycardic patients should have pacer pads in place after initial evaluation.
- Epinephrine infusion for refractory bradycardia: 2-10 mcg/min or 0.1-0.5 mcg/kg/minute (7 to 35 mcg/min in a 70 kg patient)
  - 1mg 1:10,000 in 250mL D5W / NS = 4 mcg/mL concentration
- Evaluate for treatable causes of bradycardia (B-blockade, Ca Channel blockade).

PEDIATRIC BRADYCARDIA with Pulse and Poor Perfusion

Typical HR/min

- Newborn 85 - 205
- 3mth - 2y/o 100 - 190
- 2y/o - 10y/o 60 -140
- >10 y/o 60 - 100

Typical Sinus Tachycardia Rates

- **Infants <220/min**
- **Children <180/min**

Indicators of CARDIOPULMONARY COMPROMISE

- **Hypotension**
  - 1-10 y/o lower limit = 70+(years old x 2)mmHg
  - >10 y/o lower limit = 90mmHg
- **Acutely Altered Mental Status**
  - GCS <8, Weak Cry, Unusual Irritability, Altered Responsiveness, Lethargy, or Failure to Respond to Painful Stimulus
- **Signs of Shock**

Identify and Treat Underlying Cause!
Continue:
Universal Patient Care Guideline
- **Maintain Airway / Assisted Breathing**
- **O_2** (Titrate to 94-99% SpO_2)
- **IV / IO access** (IV Guideline)
- **Monitor and 12-Lead ECG (ASAP)**
- **Check Glucose**

Rescue Breathing Ventilation Rate Without Advanced Airway:
- **NEWBORN** = 40-60/min when performed without compressions
- **Infant / Child** = 1 breath / 3 to 5 seconds

CPR Rate of 100 Compressions / Min at:
- **One Rescuer** = 30 Compressions and 2 Breaths
- **Two Rescuer** = 15 Compressions and 2 Breaths

Cardiopulmonary Compromise Continues?

YES → **CPR if HR <60/min** with Poor Perfusion despite O_2 and Ventilation

NO →
- **Support ABCs**
- **Continue O_2**
- **Continuous Monitoring**
- **Consider Consultation**

Bradycardia Persists?

NO → (Support ABCs / Continue O_2 / Continuous Monitoring / Consider Consultation)

YES →

Epinephrine 1:10,000
0.01mg/kg IV/IO q3-5min

Atropine
0.02mg/kg IV / IO
(Increased Vagal Tone or Primary AV Block)
May Repeat Once
(Minimum dose 0.1mg
Max Single dose 0.5mg)

Consider:
Transcutaneous Pacing
(Consider sedation:
Midazolam 0.05-0.1mg/kg IV / IO)

Treat Underlying Causes
- **Support ABCs**
- **Continue O_2**
- **Continuous Monitoring**
- **Consider Consultation**

Check Pulse every 2 minutes during CPR

If Pulse is lost, GO TO:
PEDIATRIC CARDIAC ARREST

Treatable causes:
- **Check & Treat compromise in ABCs**
- **Hypoglycemia**
  - D25 2mL/kg slow IV (max 25mL)
  - Glucagon 0.025mg/kg IM (max 1mg)
- **Tension Pneumothorax**

"OVERDOSE (Mothers Milk)**":**
- **B-blocker** (atenolol, metoprolol, labetalol):
  - Glucagon 0.05mg/kg (3-10mg) IV – **pretreat with ondansetron (0.15mg/kg** – max 2mg) for nausea if possible
- **Calcium channel blocker** (dilitiazem, verapamil, nifedipine)
  - Calcium chloride 10% 0.2ml/kg slow IV push
- **Narcotic**
  - Naloxone 0.1mg/kg IV / IM (max 2mg) every 2-3 mins PRN

Pearls:
- Decompensation at any time (e.g., altered MS, hypotension) should prompt treatment as unstable patient.
- All bradycardic patients should have pacer pads in place after initial evaluation.
- Evaluate for treatable causes of bradycardia (B-blockade, Ca channel blockade).
- The majority of pediatric cardiac problems are actually airway problems.
- In young, breast fed patients – evaluate for mother's medications as they can cause toxicity in the infant.
- Pediatric pacer pads should be used if available. If only adult pads are obtainable – they should be placed in the anterior-posterior position.

TACHYCARDIA w/PULSE

Signs and Symptoms:
- **Ventricular Tachycardia on EKG (rate typically ≥150/min)**
- **Conscious, Rapid Pulse**
- **Chest Pain / Shortness of Breath**
- **Palpitations**
- **Dizziness**
- **Anxiety**

Differential Diagnosis (*Wide Complex QRS >.12sec*):
- **Artifact / Device Failure**
- **Cardiac**
- **Endocrine / Metabolic**
- **Hyperkalemia**
- **Drugs**
- **Pulmonary**

Differential Diagnosis (*Narrow QRS*):
- **Wolf-Parkinson-White Syndrome**
- **Valvular Heart Disease**
- **Sick Sinus Syndrome**
- **Myocardial Infarction**
- **Electrolyte Imbalance**
- **Sinus Tachycardia / Atrial Flutter**
- **Hypoxia**
- **Drug Overdose / Toxin**
- **Hyperthyroidism**

Universal Patient Care Guideline
O_2 (if Hypoxemic)
IV / IO Guideline
Monitor and 12-lead ECG (ASAP)

METOPROLOL
5mg IV q5min X 3
Hold if SBP <100, P <60

DILTIAZEM
20mg (0.25mg/kg) IV over 2min. If no hypotension, after 15 min repeat at 25mg (0.35mg/kg)

ADENOSINE
- 1st Dose: 6mg rapid IV push: followed by NS Flush
- 2nd Dose: 12mg

Chest Pain / SOB / Dizziness?
- YES → **Chest Pain Guideline**
- NO → **Observe Reassess q 5 minutes**

"Sinus Tach"
- YES → **STABLE**
- NO → **QRS Width?** No unstable signs / symptoms, No "Sinus Tach"

STABLE
- NO → **UNSTABLE: Signs / Symptoms of:**
  - BP Low (hypotension)
  - Altered mental status
  - Signs/symptoms of shock
  - Ischemic chest pain
  - Congestive heart failure (acute)

***Synchronized Cardioversion:**
- Narrow Irregular, A-Fib
- Narrow Regular, SVT, Atrial Flutter
- Wide Regular, Stable Monomorphic VT

Consider Sedation: Midazolam 2-5mg IV / IO

QRS Width? No unstable signs / symptoms, No "Sinus Tach"

Narrow QRS? ≤0.12 Second
- Regular → **Vagal Maneuvers:** Blow through 18ga IV catheter, carotid massage, bear down.
  - **ADENOSINE: use for Regular Rhythm ONLY!**
  - **DILTIAZEM**
  - **METOPROLOL**
- Irregular → **DILTIAZEM**, **METOPROLOL**

***Synchronized Cardioversion:**
- Narrow Irregular, A-Fib
- Narrow Regular, SVT, Atrial Flutter

Consider Sedation: Midazolam 2-5mg IV / IO

Wide QRS? >0.12 Second
- Regular → Consider:
  - **AMIODARONE**

If refractory or becomes unstable at any time!

AMIODARONE
Stable Wide-QRS Tachy
- 1st Dose: 150mg IV over 10min
- Repeat prn if VT recurs
- Maintenance infusion: 1mg/min for 1st 6 hrs

- Irregular → Consider:
  - **Torsades
  - A-Fib with/or Wolff-Parkinson-White (look for a delta wave)
  - Procainamide 20-50mg/min until arrhythmia suppression, hypotension, QRS widens by >50%, or total dose 17mg/kg reached

All Pathways End with Continuous Monitoring

Pearls:
- ****Torsades de Pointes** may Benefit from early use of **Magnesium**: 1-2 grams IV over 60 min (Mix in 50ml D5W) Start drip of 0.5-1 gram/hr and titrate to effect.
- If hyperkalemia suspected (end-stage renal disease, dialysis) – administer Ca Chloride through central access or Ca Gluconate through peripheral IV.
- All patients should be warned of discomfort / feeling of heart stopping prior to adenosine administration.

***Synchronized Cardioversion**
(Increase Js per manufacture's recommendation)

Narrow Irregular, Atrial Fibrillation:
- 120-200 J biphasic

Narrow Regular, Other SVT, Atrial Flutter:
- 50-100 J, increase in stepwise fashion

Wide Regular, Stable Monomorphic VT:
- 100 J, increase in stepwise fashion

Wide Irregular:
- Defibrillate (NOT Synchronized)
- Go to: **Cardiac Arrest Guideline**

PEDIATRIC TACHYCARDIA with Pulse and Adequate Perfusion

Typical HR/min

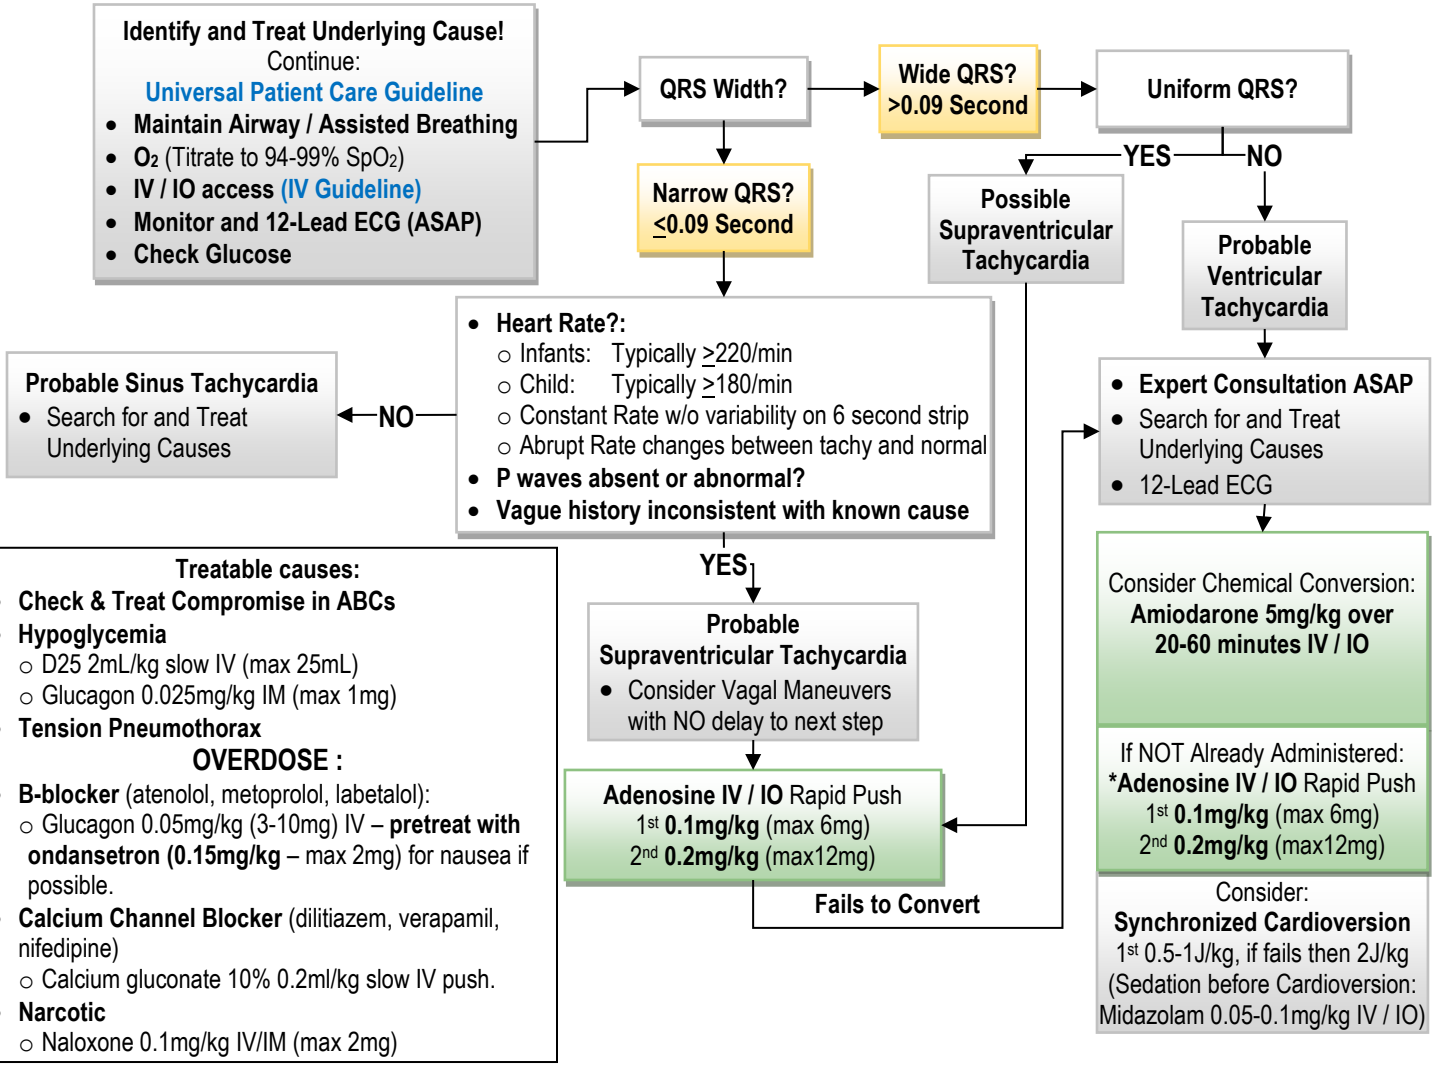
- Newborn 85 - 205
- 3mth – 2y/o 100 - 190
- 2y/o to 10y/o 60 -140
- >10y/o 60 - 100

Typical Sinus Tachycardia Rates

- **Infants <220/min**
- **Children <180/min**

Indicators of CARDIOPULMONARY COMPROMISE

- **Hypotension**
  - 1-10 y/o lower limit = 70+(years old x 2)mmHg
  - >10 y/o lower limit = 90mmHg
- **Acutely Altered Mental Status**
  - GCS <8, Weak Cry, Unusual Irritability, Altered Responsiveness, Lethargy, or Failure to Respond to Painful Stimulus
- **Signs of Shock**



Identify and Treat Underlying Cause!
Continue:
Universal Patient Care Guideline
Maintain Airway / Assisted Breathing
O2 (Titrate to 94-99% SpO2)
IV / IO access (IV Guideline)
Monitor and 12-Lead ECG (ASAP)
Check Glucose
QRS Width?
Wide QRS? >0.09 Second
Uniform QRS?
YES
NO
Narrow QRS? ≤0.09 Second
Possible Supraventricular Tachycardia
Probable Ventricular Tachycardia
Heart Rate?:
Infants: Typically ≥220/min
Child: Typically ≥180/min
Constant Rate w/o variability on 6 second strip
Abrupt Rate changes between tachy and normal
P waves absent or abnormal?
Vague history inconsistent with known cause
NO
Probable Sinus Tachycardia
Search for and Treat Underlying Causes
YES
Probable Supraventricular Tachycardia
Consider Vagal Maneuvers with NO delay to next step
Adenosine IV / IO Rapid Push
1st 0.1mg/kg (max 6mg)
2nd 0.2mg/kg (max12mg)
Fails to Convert
Expert Consultation ASAP
Search for and Treat Underlying Causes
12-Lead ECG
Consider Chemical Conversion:
Amiodarone 5mg/kg over 20-60 minutes IV / IO
If NOT Already Administered:
*Adenosine IV / IO Rapid Push
1st 0.1mg/kg (max 6mg)
2nd 0.2mg/kg (max12mg)
Consider:
Synchronized Cardioversion
1st 0.5-1J/kg, if fails then 2J/kg
(Sedation before Cardioversion: Midazolam 0.05-0.1mg/kg IV / IO)

Treatable causes:

- **Check & Treat Compromise in ABCs**
- **Hypoglycemia**
  - D25 2mL/kg slow IV (max 25mL)
  - Glucagon 0.025mg/kg IM (max 1mg)
- **Tension Pneumothorax**

OVERDOSE :

- **B-blocker** (atenolol, metoprolol, labetalol):
  - Glucagon 0.05mg/kg (3-10mg) IV – **pretreat with ondansetron (0.15mg/kg** – max 2mg) for nausea if possible.
- **Calcium Channel Blocker** (dilitiazem, verapamil, nifedipine)
  - Calcium gluconate 10% 0.2ml/kg slow IV push.
- **Narcotic**
  - Naloxone 0.1mg/kg IV/IM (max 2mg)

Pearls:

- **Vagal maneuvers:** blow through 18ga IV catheter, ice pack on forehead, carotid massage (unilateral only – listen for bruits prior to performing), or having patient blow against closed glottis ("bear down").
- ***Adenosine should be as central as possible with the "2 syringe technique" – one with adenosine and the other with the saline flush. These should be attached to a 2 port IV adapter and flush should immediately follow drug.**
- ***Adenosine should be utilized in <u>monomorphic and regular R-R interval</u> type presentation.**
- All patients should be warned of discomfort / feeling of heart stopping before adenosine administration.

PEDIATRIC TACHYCARDIA with Pulse and Poor Perfusion

Typical HR/min

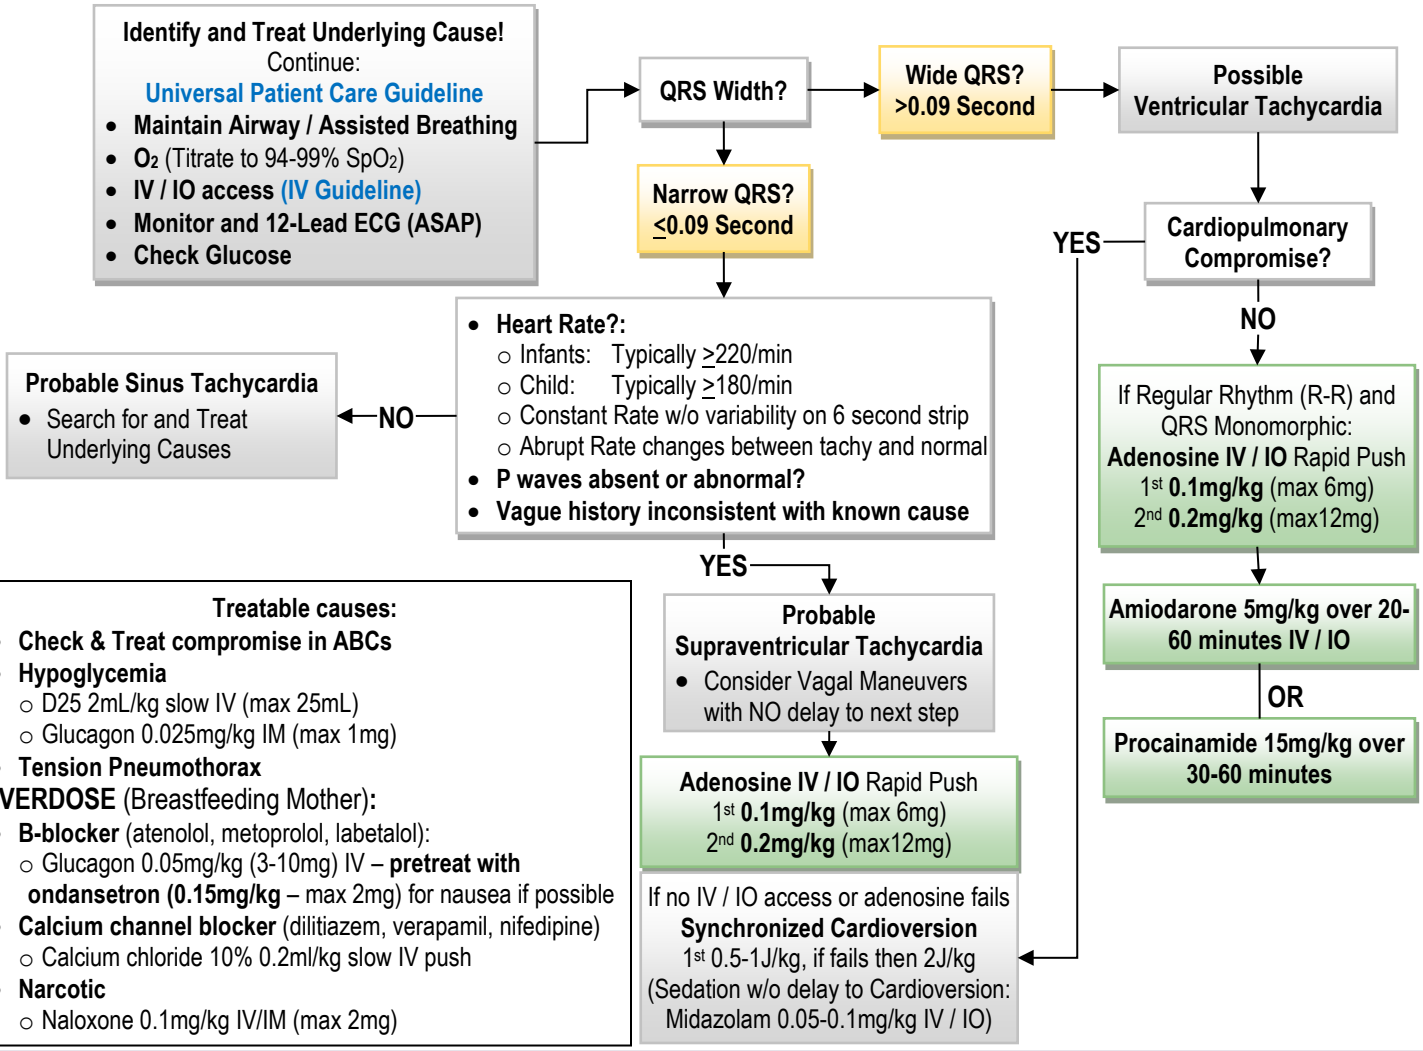
- Newborn 85 - 205
- 3mth – 2y/o 100 - 190
- 2y/o to 10y/o 60 -140
- >10 y/o 60 - 100

Typical Sinus Tachycardia Rates

- **Infants < 220/min**
- **Children <180/min**

Indicators of CARDIOPULMONARY COMPROMISE

- **Hypotension**
  - 1-10 y/o lower limit = 70+(years old X 2)mmHg
  - > 10 y/o lower limit = 90mmHg
- **Acutely Altered Mental Status**
  - GCS <8, Weak Cry, Unusual Irritability, Altered Responsiveness, Lethargy, or Failure to respond to painful stimulus
- **Signs of Shock**



Identify and Treat Underlying Cause!
Continue:
Universal Patient Care Guideline
Maintain Airway / Assisted Breathing
O2 (Titrate to 94-99% SpO2)
IV / IO access (IV Guideline)
Monitor and 12-Lead ECG (ASAP)
Check Glucose
QRS Width?
Wide QRS? >0.09 Second
Possible Ventricular Tachycardia
Narrow QRS? ≤0.09 Second
Cardiopulmonary Compromise?
YES
NO
Heart Rate?:
Infants: Typically ≥220/min
Child: Typically ≥180/min

Search for and Treat Underlying Causes
NO
YES
If Regular Rhythm (R-R) and QRS Monomorphic:
Adenosine IV / IO Rapid Push
1st 0.1mg/kg (max 6mg)
2nd 0.2mg/kg (max12mg)
Amiodarone 5mg/kg over 20-60 minutes IV / IO
OR
Procainamide 15mg/kg over 30-60 minutes
Probable Supraventricular Tachycardia
Consider Vagal Maneuvers with NO delay to next step
Adenosine IV / IO Rapid Push
1st 0.1mg/kg (max 6mg)
2nd 0.2mg/kg (max12mg)
If no IV / IO access or adenosine fails
Synchronized Cardioversion
1st 0.5-1J/kg, if fails then 2J/kg
(Sedation w/o delay to Cardioversion: Midazolam 0.05-0.1mg/kg IV / IO)

Treatable causes:

- **Check & Treat compromise in ABCs**
- **Hypoglycemia**
  - D25 2mL/kg slow IV (max 25mL)
  - Glucagon 0.025mg/kg IM (max 1mg)
- **Tension Pneumothorax**

OVERDOSE (Breastfeeding Mother)**:**

- **B-blocker** (atenolol, metoprolol, labetalol):
  - Glucagon 0.05mg/kg (3-10mg) IV – **pretreat with ondansetron (0.15mg/kg** – max 2mg) for nausea if possible
- **Calcium channel blocker** (dilitiazem, verapamil, nifedipine)
  - Calcium chloride 10% 0.2ml/kg slow IV push
- **Narcotic**
  - Naloxone 0.1mg/kg IV/IM (max 2mg)

Pearls:

- **Vagal maneuvers:** blow through 18ga IV catheter, ice pack on forehead, carotid massage (unilateral only – listen for bruits prior to performing), or having patient blow against closed glottis ("bear down").
- **Adenosine should be given with the "2 syringe technique" – one with adenosine and the other with the saline flush. These should be attached to a 2 port IV adapter and flush should immediately follow drug.**
  - All patients should be warned of discomfort / feeling of heart stopping before adenosine administration.

POST-CARDIAC ARREST CARE

Signs and Symptoms:
- **Return of Spontaneous Circulation**
- **Pulse**
- **Respirations**

Differential Diagnosis:
- **Continually Address Primary Pathology Associated with Arrest**

Universal Patient Care Guideline

Continuous Monitoring and Maintain:
- **Circulation:** Palpable Pulses and BP
- **O_2:** Sat < 90% (may need advanced airway)
- **12 lead ECG / Defibrillator**
- **IV / IO access** (IV Guideline)

Consider as appropriate: **Post-Resuscitation Induced Hypothermia Guideline**

Hypotension (SBP <90 mm Hg)

Fluid bolus ***See pearls Reperfusion** and **Trauma Patients**

For Refractory Hypotension Consider:
Norepinephrine
0.1-0.5 mcg/kg/mil
Epinephrine
2-10 mcg/min

Consider Treatable Causes

Move to appropriate Cardiac guideline (opposite side of page) based on changes in Pulse and ECG.

Changes in Pulses or Significant Ectopy

Loss of Pulses, or onset of VF / pulseless VT, asystole / PEA: Move to **Cardiac Arrest Guideline**

Symptomatic Bradycardia move to **Bradycardia with Pulse Guideline**

Symptomatic Tachycardia, Pulse >150/min move to **Tachycardia with Pulse Guideline**

Reversible Causes:
- **Hypovolemia**
- **Hypoxia**
- **Hydrogen ion (acidosis)**
- **Hypo-hyperkalemia**
- **Hypothermia**
- **Hypo-Hyperglycemia**
- **Tension pneumothorax**
- **Tablets/toxin**
- **Tamponade, cardiac**
- **Thrombus – cardiac**
- **Thrombus – pulmonary**

Pearls:
- Hyperventilation may cause hypotension and/or recurrence of cardiac arrest in the post-resuscitation phase and must be avoided.
- Most patients will require ventilator assistance in the post-resuscitative phase.
- In non-airway controlled patients, it is important to prevent aspiration following resuscitation. For this reason, patients should be rotated onto their side (non-spinal immobilization) or be closely monitored in case vomiting occurs.
- ***Reperfusion:** 1-2 L IVF and consider use of a pressor IV / IO **Drip** – **EPINEPHRINE 2-10mcg/min** or **NOREPINEPHRINE 0.1-0.5 mcg/kg/min: 70kg adult: 7-35mcg/min**.
  - **Dopamine should be started at a low dose (5mcg/kg/min)** and titrated up to maintain a SBP >90. The same applies norepinephrine.
- ***Trauma patients** post-resuscitation should have fluid resuscitation consistent with hypotensive resuscitation guidelines. Maintain body core temperature 32-36 degrees Celsius for at least 24 hours.

HYPERTENSION

Signs and Symptoms of ***Hypertensive Crisis w/ end organ damage.***

One of These:

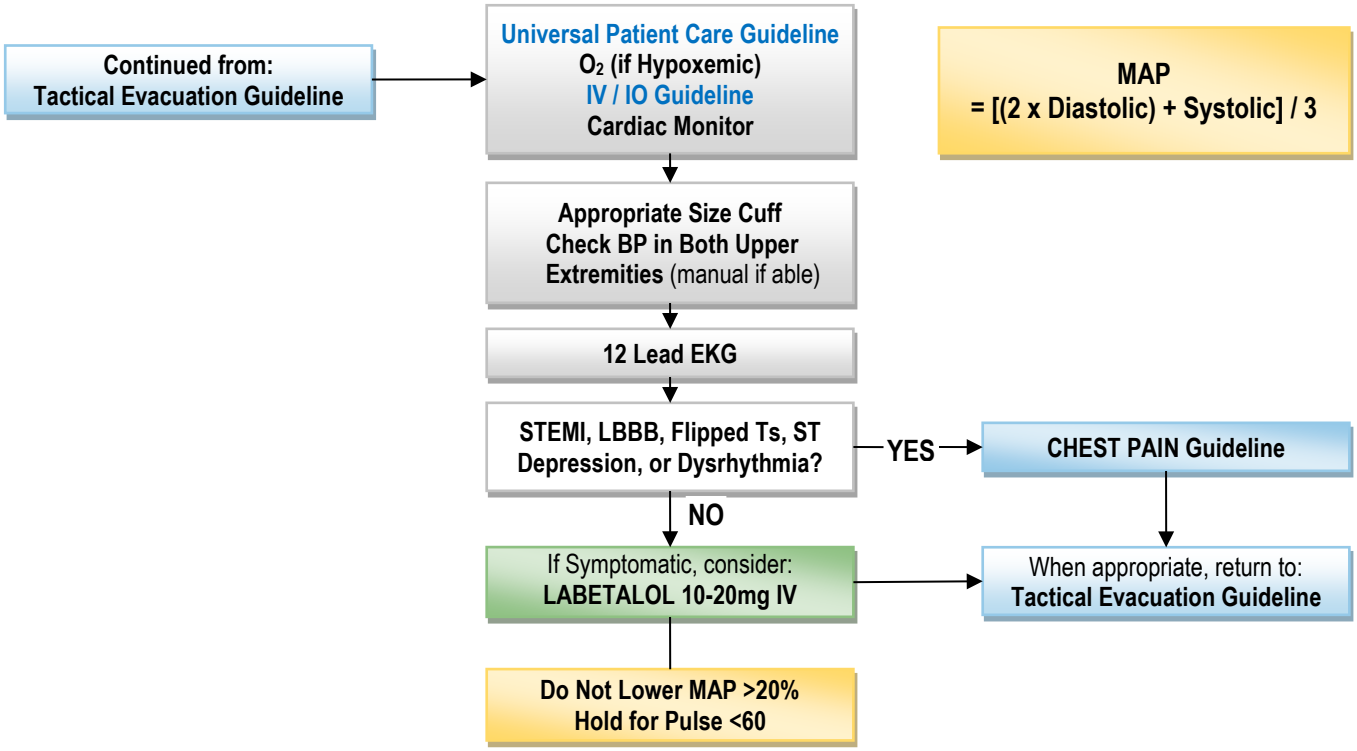
- **Systolic BP 185+**
- **Diastolic BP 110+**

Plus One of These:

- **Altered Mental Status**
- **Blurred Vision**
- **Dizziness / Stroke Symptoms**
- **Chest Pain**

Differential Diagnosis:

- **Primary CNS injury (Cushing's Reflex)**
- **Myocardial Infarction**
- **Aortic Dissection**
- **Pre-Eclampsia / Eclampsia**
- **Toxin / Medication**



Pearls:

- Do not treat elevated blood pressure based on one set of vital signs.
- Improper cuff size and equipment malfunction are common reasons for abnormally high readings.
- If patient has none of the above symptoms of hypertensive emergencies – they do not require treatment of their blood pressure.
- In setting of stroke – do not treat blood pressure unless SBP >220 and/or DBP >120 or signs of end-organ involvement.
  - Elevated BP is required to maintain perfusion during a stroke.
- Only lower MAP approximately 20% with slow, titrated doses – hypertensive patients often need elevated BP to maintain organ / CNS perfusion. MAP = [(2 x Diastolic) + Systolic] / 3
- **Labetalol is contraindicated in patients with severe asthma / COPD. In these patients, NTG can be given to lower BP if absolutely necessary. Labetalol doses above are for symptomatic hypertension patients, not hypertension alone.**
- **Metoprolol is contraindicated for CHF, Acute PE, bronchospasms, bradycardia, hypotension, hx of asthma, and thyrotoxicosis.**

ALTITUDE ILLNESS

Differential Diagnosis:
- **Head Trauma**
- **Stroke**
- **CNS Tumor / Mass / Bleed / Infection**
- **Endocrine Disorder**
- **Toxic Ingestion**
- **Pneumonia / PE**
- **Cephalgia**

Acute Mountain Sickness (AMS)	High Altitude Cerebral Edema (HACE)	High Altitude Pulmonary Edema (HAPE)
• Headache • Nausea / Vomiting • Lethargy • Dizziness	• AMS Symptoms • Unstable Gait • Drowsiness • Confusion • Coma	• Cough • Dyspnea • Pink Frothy Sputum • Cyanosis • Hyperthermia

Continued from: Tactical Evacuation Guideline

Universal Patient Care Guideline
O_2 (ASAP)
IV / IO Guideline
Cardiac Monitor (ASAP)

Hypothermia Precautions
Hypothermia Guideline

Immediate / 1st Line Care for any form of Altitude Illness:
- **Rapid Descent (as mission able)**
- **O_2**
- **Gamow Bag (when descent is not possible)**

Symptoms

Headache
→ **Altered Mental Status or Ataxia?**
→ YES (HACE) → **Rapid Descent** Consider: **Gamow Bag (*See Pearls)**
→ **O_2** (If not previously started)
→ **Dexamethasone: Initial Loading dose 10mg IV / IO** (6mg if 4mg already provided) (then 4mg IV / IO / PO q6hr)
→ **Ondansetron 4-8mg IV / IO**
→ Consider:
- **Acetaminophen 650-1000mg PO**
- **Ibuprofen 600-800mg PO**

NO (AMS) → **Prevent Further Ascent**
→ **O_2** (If not previously started)
→ **Descend 500-1000m if able**
→ **Acetazolamide 125-250mg PO**
→ **Dexamethasone 4mg IV / IO / PO q6hr**
→ **Altered Mental Status**
→ YES → **Rapid Descent** Consider: **Gamow Bag (*See Pearls)**
→ NO → Consider: **Acetaminophen 650-1000mg PO**, **Ibuprofen 600-800mg PO**

Pulmonary Symptoms (HAPE)
→ **Rapid Descent** Consider: **Gamow Bag (*See Pearls)**
→ **O_2** (If not previously started)
→ **Nifedipine 10mg PO q4-6hr**
→ Consider: **Assisted Ventilation (PPV)**
→ **Altered Mental Status or Ataxia?**
→ YES → **Dexamethasone: Initial Loading dose 10mg IV / IO** (6mg if 4mg already provided) (then 4mg IV / IO / PO q6hr)
→ NO → Consider: **Acetaminophen 650-1000mg PO**, **Ibuprofen 600-800mg PO**

When appropriate, return to: **Tactical Evacuation Guideline**

Pearls:
- **The treatment of choice for all altitude-related illnesses is supplemental O_2 and descent** – at least 500-1000m. If unable to descend, a hyperbaric bag (Gamow bag) can be utilized if available.
  - If unable to descend immediately - as soon as HACE or HAPE are suspected, the crew must begin engaging actively with the PIC or other tactical commander to work the issue of descent ASAP.
- **Acetazolamide should not be given to those patients with Sulfa allergies or known Sickle Cell Anemia**.
- **High-Altitude Pulmonary Edema (HAPE)** patients may have crackles / fever / hypoxia.
- **High-Altitude Cerebral Edema (HACE)** patients have AMS and may have tremors, HACE often occurs along with HAPE.
  - ANY altered mental status / confusion / abnormal gait should be presumed to have cerebral edema and descent should be undertaken immediately.
- *Descent should be done with the least amount of patient exertion possible to prevent worsening of the condition.

Animal and Insect Bites and Stings

Signs and Symptoms:

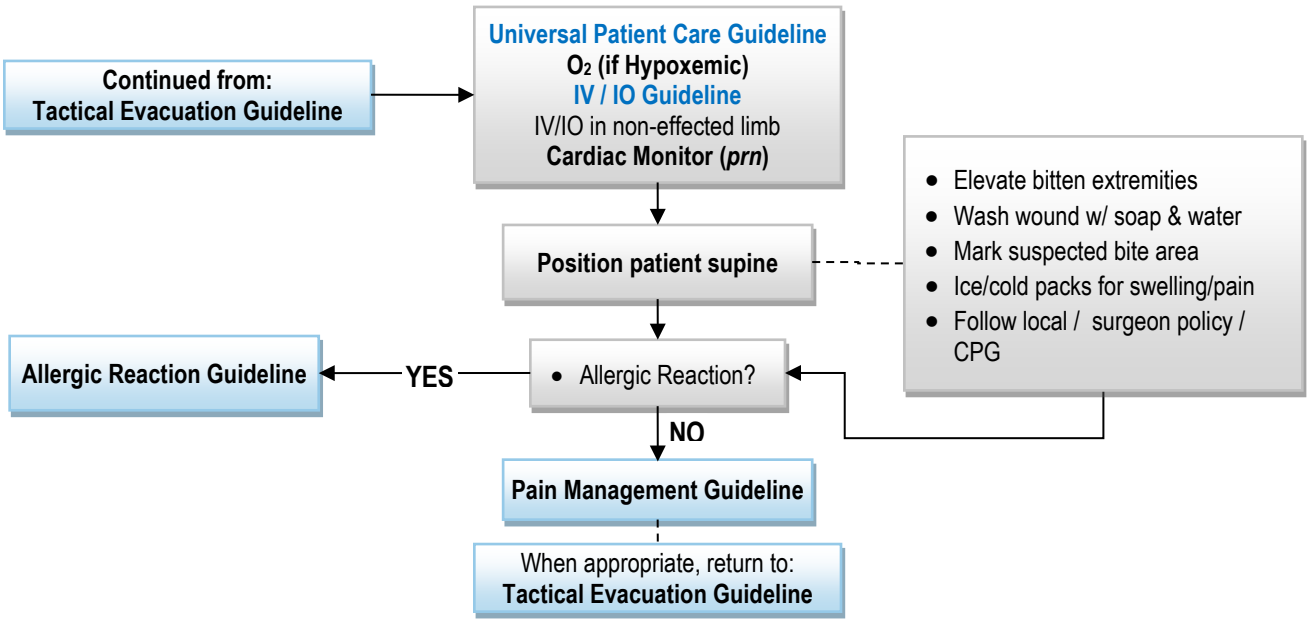
- **Rash, Skin Break, Wound, Retained Stinger**
- **Pain, Swelling, Erythema**
- **Bleeding / Discharge**
- **Shortness of Breath / Wheezing / Throat Tightness**
- **Hypotension or Shock**

Differential Diagnosis:

- **Bite / Envenomation**
- **Other Allergic Reaction**
- **Anaphylaxis**
- **Rabies / Tetanus Risk**

For SPIDER / SCORPION see: **SPIDER and SCOPRION Envenomation**

For SNAKEBITE see: **Snakebite Envenomation**

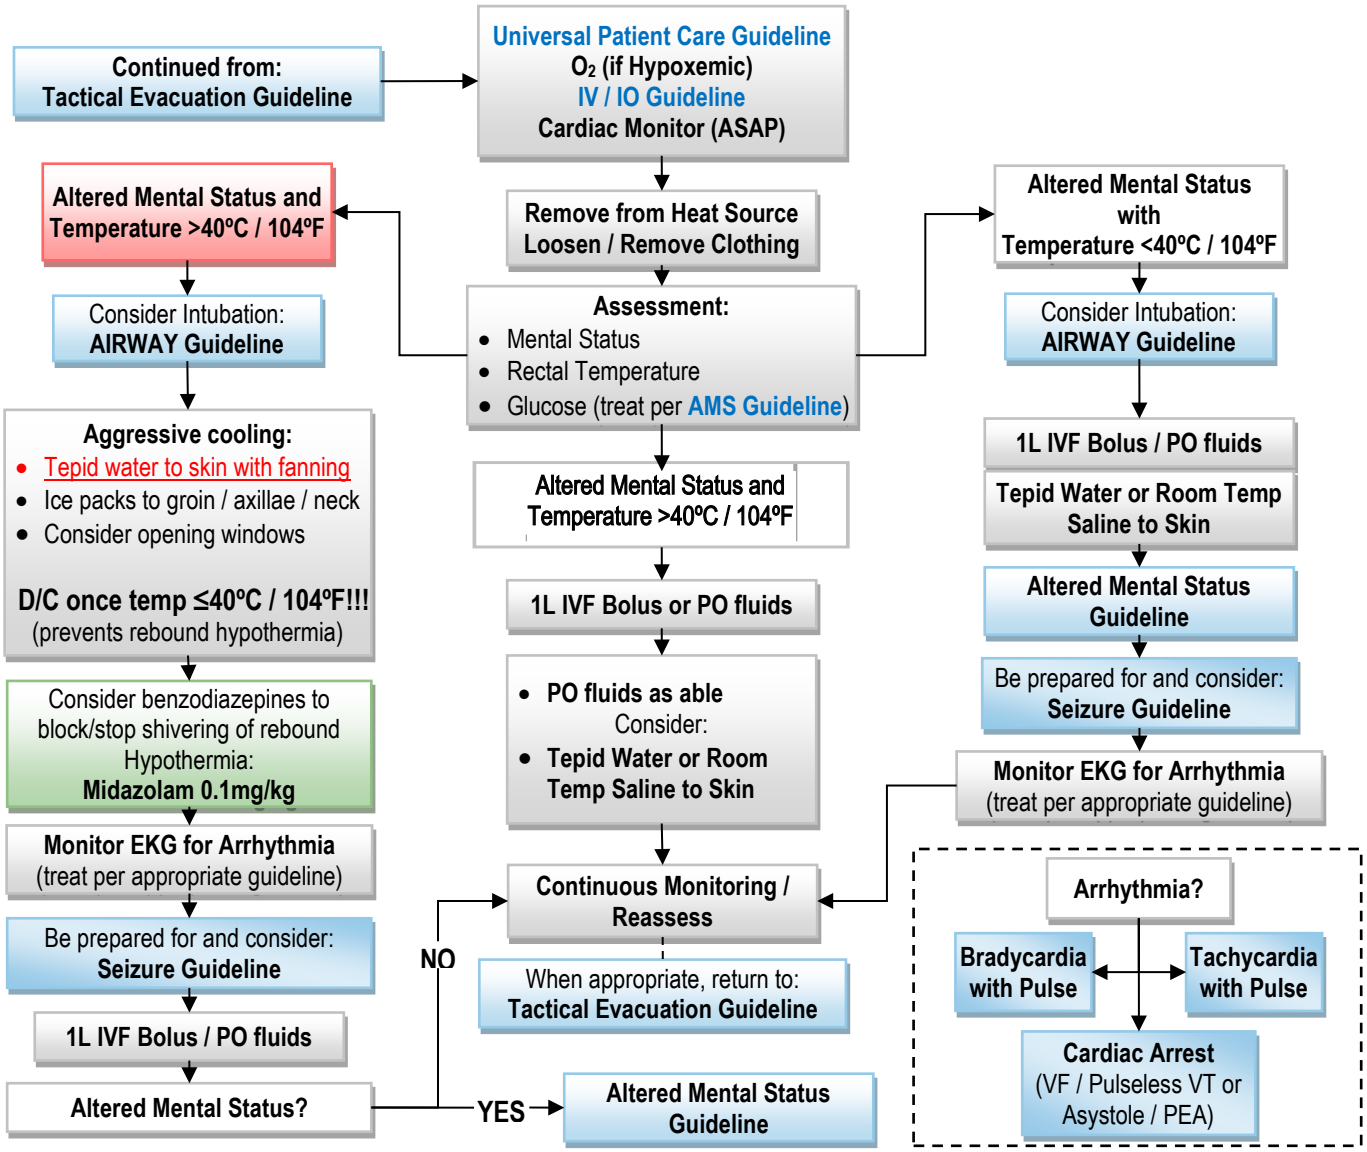


Pearls:

- Never attempt to capture / transport a live animal / insect.
- **Anaphylactic reactions should be treated as soon as recognized.**
- Review country environmental concerns before deployment or visitation.
- All animals should be considered rabid outside the U.S. until proven otherwise. This excludes rodents, which do not carry rabies.
- Consider IV administration of Calcium Gluconate if Tetany develops.
- Elevate effected limb to reduce swelling
- ***DO NOT apply constricting bandages or tourniquets*** as these may worsen local tissue injury and increase the risk of permanent disability.
- ***DO NOT*** cut, suck, electrocute, burn, or use chemicals on the envenomation site

HYPERTHERMIA

Signs and Symptoms:	Differential Diagnosis:	
• Altered Mental Status • Loss of Consciousness • Hot / Dry or Sweaty Skin • Hypotension or Shock • Seizure • Nausea / Vomiting	• Infection • Dehydration • Thyroid Storm • Medications / Toxin • Delirium Tremens • Heat Cramps	• Heat Exhaustion • Heat Stroke • CNS Lesions or Tumors



Continued from: Tactical Evacuation Guideline
Universal Patient Care Guideline
O2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)
Remove from Heat Source
Loosen / Remove Clothing
Assessment:
Mental Status
Rectal Temperature
Glucose (treat per AMS Guideline)
Altered Mental Status and Temperature >40ºC / 104ºF
Consider Intubation: AIRWAY Guideline
Aggressive cooling:
Tepid water to skin with fanning
Ice packs to groin / axillae / neck
Consider opening windows
D/C once temp ≤40ºC / 104ºF!!!
(prevents rebound hypothermia)
Consider benzodiazepines to block/stop shivering of rebound Hypothermia:
Midazolam 0.1mg/kg
Monitor EKG for Arrhythmia
(treat per appropriate guideline)
Be prepared for and consider:
Seizure Guideline
1L IVF Bolus / PO fluids
Altered Mental Status?
NO
YES
1L IVF Bolus or PO fluids
PO fluids as able
Consider:
Tepid Water or Room Temp Saline to Skin
Continuous Monitoring / Reassess
When appropriate, return to:
Tactical Evacuation Guideline
Altered Mental Status Guideline
Altered Mental Status with Temperature <40ºC / 104ºF
Consider Intubation: AIRWAY Guideline
1L IVF Bolus / PO fluids
Tepid Water or Room Temp Saline to Skin
Altered Mental Status Guideline
Be prepared for and consider:
Seizure Guideline
Monitor EKG for Arrhythmia
(treat per appropriate guideline)
Arrhythmia?
Bradycardia with Pulse
Tachycardia with Pulse
Cardiac Arrest
(VF / Pulseless VT or Asystole / PEA)

Pearls:

- The single best method to cool patient is sublimation-sprinkling with water and fanning to evaporate off the skin
- Groups at elevated risk for heat emergencies: elderly, very young, highly active.
- Use of alcohol, cyclic antidepressants, phenothiazines, and anticholinergic medications increase risk.
- Cocaine, ecstasy, amphetamines, and aspirin toxicity can all raise body temperature.
- Sweating does not exclude heat stroke / heat illness.
- In conscious patients that can protect their airway, encourage intake of PO fluids and electrolytes.

HYPOTHERMIA

Signs and Symptoms:
- Cold, Clammy
- Shivering / Lack of Shivering
- Mental Status Changes
- Extremity Pain / Numbness
- Bradycardia / Arrhythmia
- Hypotension or Shock

Differential Diagnosis:
- Sepsis
- Environmental Exposure
- Hypoglycemia
- CNS Dysfunction
- Toxic Ingestion

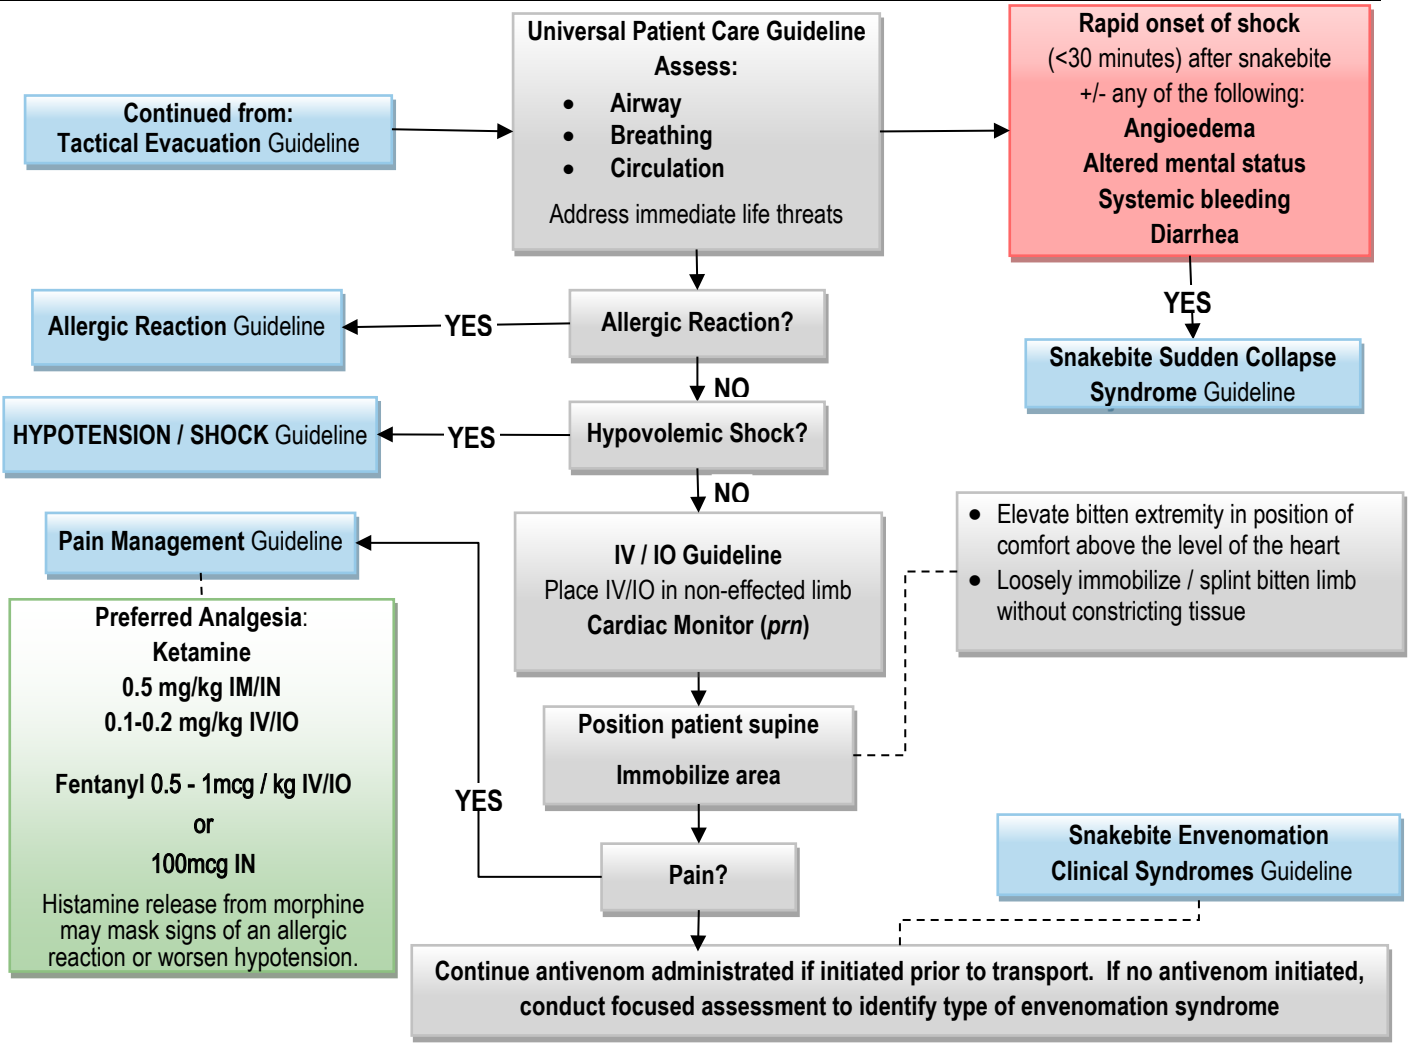
O2 (if Hypoxemic)
IV / IO Guideline
Cardiac Monitor (ASAP)
FROSTBITE
Extremity or body part with suspected frostbite must be protected to prevent further injury (wrapped and covered with a dry blanket). Do not attempt active rewarming unless no risk of refreezing.
Remove Wet Clothing
Assessment:
Mental Status
Rectal Temperature
Glucose (treat per AMS Guideline while re-warming)
Core Temperature <95ºF / 35ºC
Patient is Alert, w/o Arrhythmia, and is Actively Shivering
AMS
Core Temp <95º / 35ºC with AMS, Arrhythmia, or Absence of Shivering
Dry Blankets
Hypothermia Blanket
Warm PO fluids (if available)
WARMED IV FLUIDS
1L IVF Bolus
Handle Very Gently
HPMK Kit / Hypothermia Blankets
Dry Clothing
Hot Packs to Groin, Axilla, Abdomen (avoid contact burn)
Target re-warming
(D/C warmed IV Fluids)
12-lead EKG
Arrhythmia?
YES
NO
Submersion Injury Guideline
Airway Guideline
When appropriate, return to: Tactical Evacuation Guideline
Treat per Appropriate Guideline
Transport to ECMO team or nearest hospital
Bradycardia with Pulse Guideline
Cardiac Arrest Guideline
Tachycardia with Pulse Guideline

Pearls:
- "No patient is dead until they are warm and dead."
- Hypothermia defined as core temperature <95ºF (35ºC).
- With temperatures <31ºC (88ºF) ventricular fibrillation is common. Cardiac muscle becomes very irritable as temperature drops and rough handling may induce a cardiac dysrhythmia.
- With temperatures below 30ºC (86ºF) shivering ceases – removing an important heat production source.
- The pulse may be very slow in hypothermic patients – should wait at least one minute to feel pulse.
- Arrhythmias at temperature >30ºC (86ºF) treated similar to normo-thermic patients with the addition of active re-warming.
- At temperatures <30ºC (86ºF) one defibrillation can be attempted, but withhold further attempts / meds until temp >30ºC (86ºF).

Snake Envenomation Management: General Principles

If the patient is being medically evacuated from the field or between roles of care, confirm that the receiving facility has an adequate supply of the appropriate regionally specific antivenoms. *Evacuation is not an alternative to antivenom administration. A patient whose snakebite warrants evacuation will require antivenom. The earlier it is given the greater the chance of full recovery without permanent disability.* ***DO NOT*** *delay administration of antivenom in the field if available to a patient with an envenomation.*

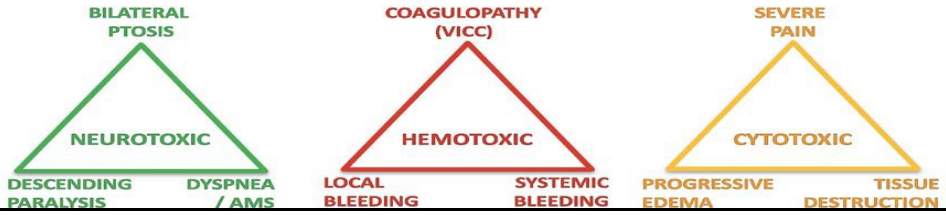


Pearls:

- ***Don't try to ID the snake.*** Snake identification is unreliable and should not be purposely attempted.
- ***DO NOT*** attempt to catch or kill the snake; treatment is clinical and the snake species does not need to be identified. Never attempt to capture or transport a live snake
- Amount of envenomation from snake bites can be variable or dry bites" Snakebite treatment should always be determined by the clinical presentation and evolution of signs and symptoms in the patient
- ***DO NOT*** use ice / tourniquets or constricting bandages as these may worsen local tissue injury and increase the risk of permanent disability.
- If a tourniquet is already in place, ***do not*** remove it until you are ready to treat and resuscitate the patient as a rapid decompensation can occur
- Anaphylactic reactions or hypovolemic shock should be treated as soon as recognized.
- Snakebites are clinically dynamic emergencies and can change dramatically until control has been achieved.

Snakebite Envenomation Clinical Syndromes

There are 3 major clinical syndromes of snakebite envenomation worldwide and 3 major signs and symptoms of each. All dangerous snakes capable of injuring or killing a human will produce at least one sign or symptom from at least one of the 3 major snakebite syndromes. Specific antivenoms required will vary regionally but the major triads are applicable globally.



Continued from:
Snake Envenomation Management: General Principles

Conduct Focused Assessment and Examination to Identify Envenomation Syndrome

With permanent marker:

- Write time of bite on patient
- Circle bite mark on patient

Conduct rapid examination for signs of:

- **Pain**
- **Swelling (edema)**
- **Tissues destruction (necrosis)**

YES → **CYTOTOXIC SYNDROME:**

- Mark leading edge of pain with a dash line (- - -) and annotate time
- Mark leading edge of edema with a solid line and annotate time

It is important to keep the limb significantly elevated (> 60° is ideal) whenever possible to limit dependent edema and swelling.

NO

Rapid examination for signs of local or systemic bleeding:

- persistent local bleeding > 30 mins from the bite wound (if visible) or other lesions
- Inspect the molar gingiva and other mucosa for signs of systemic bleeding

YES → **HEMOTOXIC SYNDROME:**

- Internal and external active bleeding should cease within 30 – 60 minutes of antivenom administration once the appropriate dose has been given.
- Packed red blood cell or whole blood transfusion can be considered if the patient is in hemorrhagic shock
- Platelets, fresh frozen plasma, cryoprecipitate, TXA, and ***other agents are not effective in these cases*** due to the mechanism of the venoms.

NO

Rapid examination for signs of neuromuscular weakness:

- Evaluate respiratory muscle weakness by single breath count testing
- Dyspnea?.
- Signs and symptoms of descending flaccid paralysis: Ptosis, diplopia, neck flexor muscle weakness, bulbar weakness, etc.
- Signs and symptoms of parasympathetic / cholinergic crisis: SLUDGE mnemonic - Salivation, Lacrimation, Urination, Defecation, GI distress, Emesis
- Altered Mental Status?

YES → **NUEROTOXIC SYNDROME:**

Anticipate the need for aggressive airway management with intubation and prolonged ventilation in all patients presenting with neurotoxic envenomation.

Cholinergic Crisis? → **Consider:**
Atropine 0.5mg IV/IO

- Titrated by auscultation to dry up bronchial and oral hypersecretions

Pediatric Dose:
0.01mg/kg up to .25mg

Refer to JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG) Global Snake Envenomation Management (CPG ID: 81) for 1st and 2nd line ANTIVENOM based on Region and Syndrome. Follow JTS CPG for ANTIVENOM administrations.

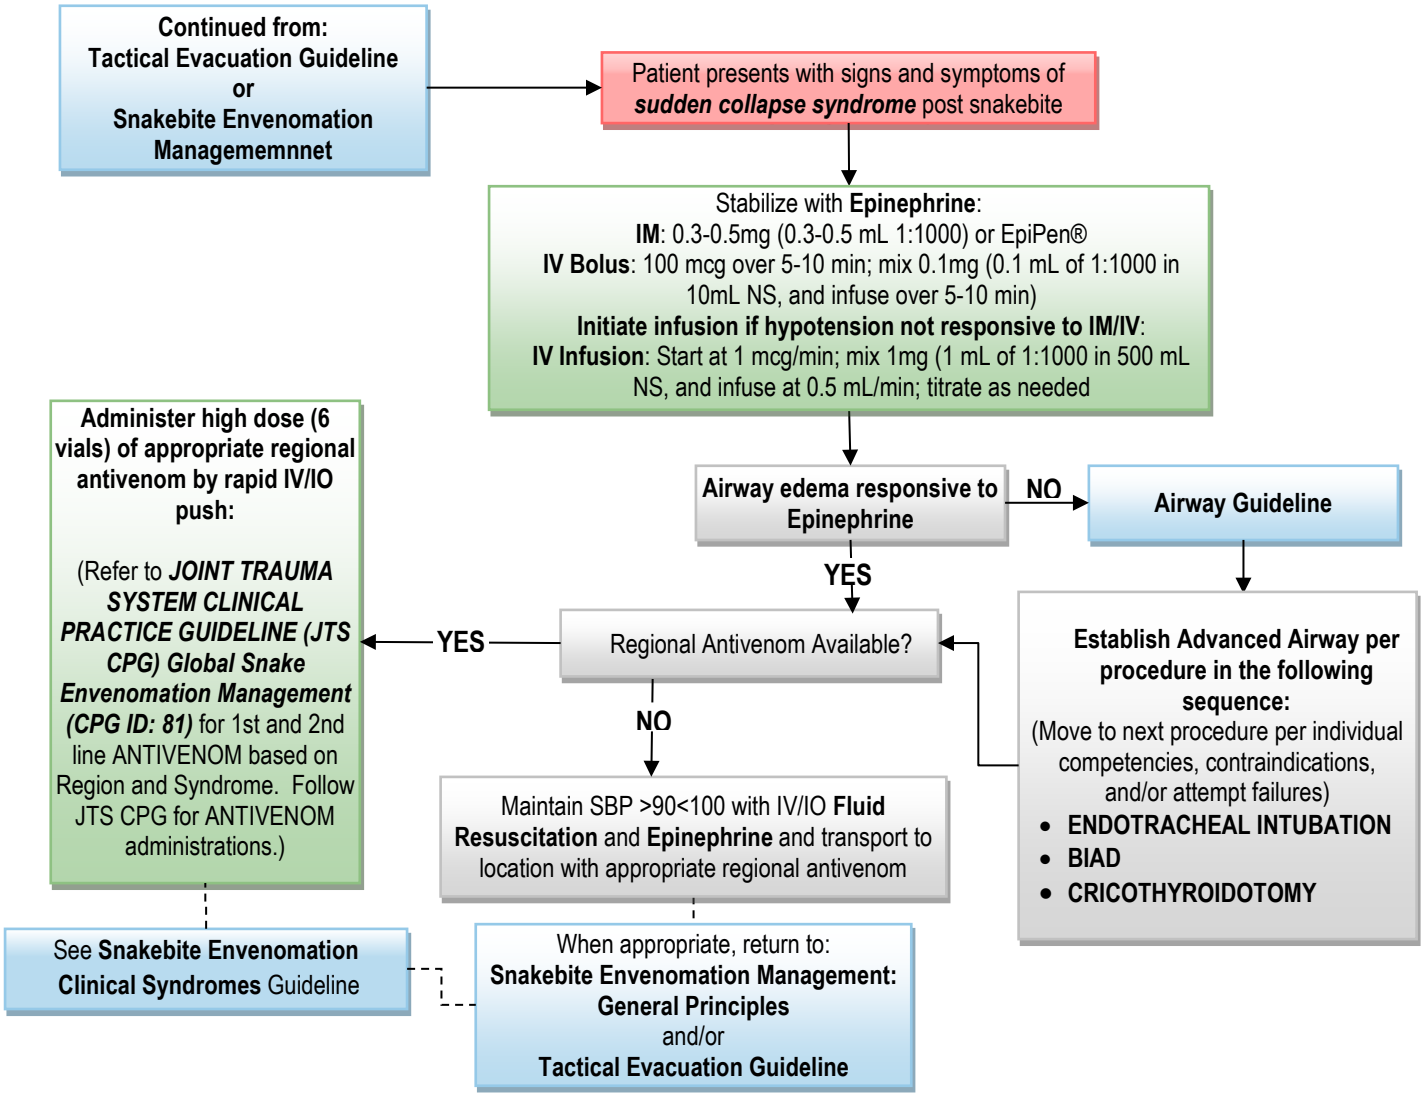
SNAKEBITE SUDDEN COLLAPSE SYNDROME

Signs and Symptoms:

- **Rapid onset of Shock (<30 min) from bite with any of the following:**
  - **Angioedema**
  - **Altered Mental Status**
  - **Systemic Bleeding**
  - **Diarrhea**

Differential Diagnosis:

- **Neurotoxic Syndrome**
- **Allergic reactions**



Continued from:
Tactical Evacuation Guideline
or
Snakebite Envenomation Managememnnet
Patient presents with signs and symptoms of sudden collapse syndrome post snakebite
Stabilize with Epinephrine:
IM: 0.3-0.5mg (0.3-0.5 mL 1:1000) or EpiPen®
IV Bolus: 100 mcg over 5-10 min; mix 0.1mg (0.1 mL of 1:1000 in 10mL NS, and infuse over 5-10 min)
Initiate infusion if hypotension not responsive to IM/IV:
IV Infusion: Start at 1 mcg/min; mix 1mg (1 mL of 1:1000 in 500 mL NS, and infuse at 0.5 mL/min; titrate as needed
Airway edema responsive to Epinephrine
NO
Airway Guideline
YES
Regional Antivenom Available?
YES
NO
Administer high dose (6 vials) of appropriate regional antivenom by rapid IV/IO push:
(Refer to JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG) Global Snake Envenomation Management (CPG ID: 81) for 1st and 2nd line ANTIVENOM based on Region and Syndrome. Follow JTS CPG for ANTIVENOM administrations.)
Establish Advanced Airway per procedure in the following sequence:
(Move to next procedure per individual competencies, contraindications, and/or attempt failures)
ENDOTRACHEAL INTUBATION
BIAD
CRICOTHYROIDOTOMY
Maintain SBP >90<100 with IV/IO Fluid Resuscitation and Epinephrine and transport to location with appropriate regional antivenom
See Snakebite Envenomation Clinical Syndromes Guideline
When appropriate, return to:
Snakebite Envenomation Management: General Principles
and/or
Tactical Evacuation Guideline

Pearls:

- Anaphylactic reactions (or hypovolemic shock) should be treated aggressively while simultaneously treating for severe envenomation with appropriate regional antivenom.
- Priority of care for a patient in snakebite sudden collapse syndrome is the consideration of the shorter of two options: ***evacuating the patient to a location with antivenom*** or ***bringing the antivenom to the patient.***
- Most patients presenting with hypotension or angioedema are responsive to epinephrine, but may require IV epinephrine infusions to achieve this effect if they are unresponsive to IM epinephrine

Global Spider and Scorpion Envenomation

Background:

Spider and scorpion envenomations can occur in many environments in which the military operates. Many arthropods possess a significant venom but lack a sufficient apparatus (fangs or talon) to inject it into humans. Most bites and stings involve more danger from anaphylaxis, but several species of spiders and scorpions have significant neurotoxic, cytotoxic, or hemotoxic venoms. While most spider and scorpion envenomations result in mild symptoms, severe toxicity and death can occur. Anaphylaxis is the most concerning initial effect. Recognize and treat it immediately using standard acute allergic reaction therapies. Anaphylaxis from an arthropod envenomation is not an indication for antivenom.

SPIDERS:

While many spider species produce venom, the vast majority lack sufficiently large or strong enough fangs to penetrate human skin and cause clinically significant effects. However, spiders venomous to humans can be found throughout much of the world. The chart below provides information regarding clinically significant venomous spider species.

Clinically Significant Venomous Spider Species			
	Widow Spiders *(Latrodectus spp)* *a.k.a* *Black Widow* *Red Widow* *Brown Widow*	**Violin Spiders** (Laxosceles reclusa) a.k.a Brown Recluse Fiddleback Spider	**Funnel Web Spiders** (Atrax) a.k.a Australian Funnel-Web Spider
Africa	X	X	
Asia	X	X	
Australia	X	X	X

Antivenom Available	Yes	No	Yes

Global Spider and Scorpion Envenomation (Continued)

Scorpions:

Scorpions envenomate humans by stinging them with the telson on their tail. Around 20 species of medically important (meaning potentially lethal to humans) scorpions are known, and all but one of these (Hemiscorpius lepturus) are members of the Buthidae family. Buthidae family contains the large genera Ananteris, Centruroides, Compsobuthus, and Tityus. Centruroides are the only clinically significant venomous scorpion indigenous to the United States (i.e. Bark Scorpions). The majority of medically significant envenomations occur in the Middle East, tropics (e.g., Southwest Asia, India, Central and South America), and North Africa.

Scorpion venoms are complex and can include phospholipase, acetylcholinesterase, hyaluronidase, serotonin, and neurotoxins. Scorpion venom increases neuronal release by blocking inactivation of the sodium channel, resulting in an increase in the amplitude and duration of neuron action potential. The overall result is excess stimulation of the central nervous system, the neuromuscular system, the sympathetic nervous system, and the parasympathetic nervous system.

The components of scorpion venom are species specific and generally fall into the categories of neurotoxic and cardiotoxic; however, this terminology is misleading since the cardiotoxic effects are secondary to an excess release of catecholamines stimulated by the nervous system. The venom of the unique species, Hemicorpius lepturus, found in Iraq and Iran is predominately cytotoxic, similar to the brown recluse spider.

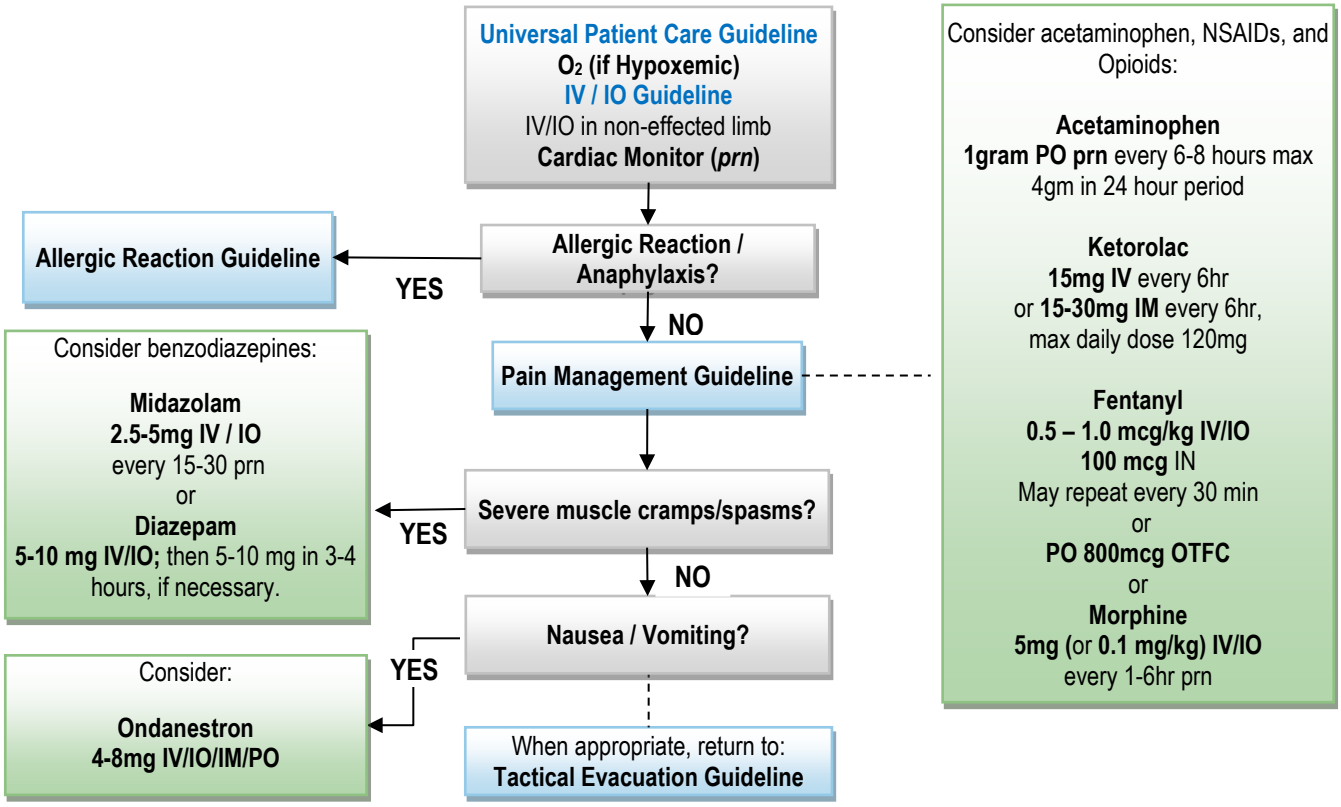
Antivenom is available for some species; data regarding the benefits and risks of many of these antivenoms are significantly limited. In patients with moderate to severe symptoms refractory to analgesics and benzodiazepines, antivenom, if available, may be indicated. Due to the high risk of immediate or delayed allergic reactions to these antivenoms administration should be done at a controlled clinical location and pre-hospital treatment should be focused on supportive care. Intravenous histamine antagonists (i.e. diphenhydramine), steroids, and epinephrine should be immediately available at the patient's bedside prior to antivenom administration. The Joint Trauma System Clinical Practice Guideline: Global Spider and Scorpion Envenomation Management (CPG ID: 84) contains a list of antivenoms available by country. (https://jts.amedd.army.mil/assets/docs/cpgs/Global_Spider_and_Scorpion_Envenomation_Management_09_Feb_2021_ID84.pdf)

Prehospital/En Route Care Treatment Goals for Spider and Scorpion Bites and Stings:

Some moderate to severe cases of envonomations will require medical evacuation to a treatment facility with the capability to administer antivenom. En Route Care consists primarily of supportive care and pain management. En route care providers should be prepared to counter cholernergic, adrenergic, sympathetic and parasympathetic effects. Aggressive use of benzodiazepines as indicated for agitation, neuromuscular stimulation, tachycardia, and hypertension. Secure the airway and initiate mechanical ventilation if indicated. Anaphylaxis is the most concerning initial effect. See specific treatment guidelines for Widow Spiders, Funnel-Web Spiders and Scorpions for additional guidance.

Widow Spider Envenomation

Patients may or may not feel a pinprick upon the initial bite. A pair of small red spots at the envenomation site may be visible; however, the bite site is often not located. Some patients do not develop systemic toxicity. In those patients who do, symptoms typically begin 15 to 60 minutes following the envenomation. The primary symptom is painful muscle cramping, starting at the bite site and progressing towards the center of the body. Patients may develop a painful, rigid abdomen secondary to abdominal muscle spasm which may be mistaken for peritonitis. The pain increases over time and may occur in waves. In some cases, the patient develops a temporary diaphoretic, grimaced, and contorted appearance of the face referred to as "facies latrodectismica." Other symptoms include vomiting, diaphoresis, tachycardia, hypertension (often profound), and restlessness. Symptoms of Latrodectus envenomation last hours to days. Fatalities from Latrodectus envenomation are exceedingly rare and, when they do occur, are secondary to cardiac arrest (presumably from severe hypertension in patients with predisposing medical conditions) and wound infection.

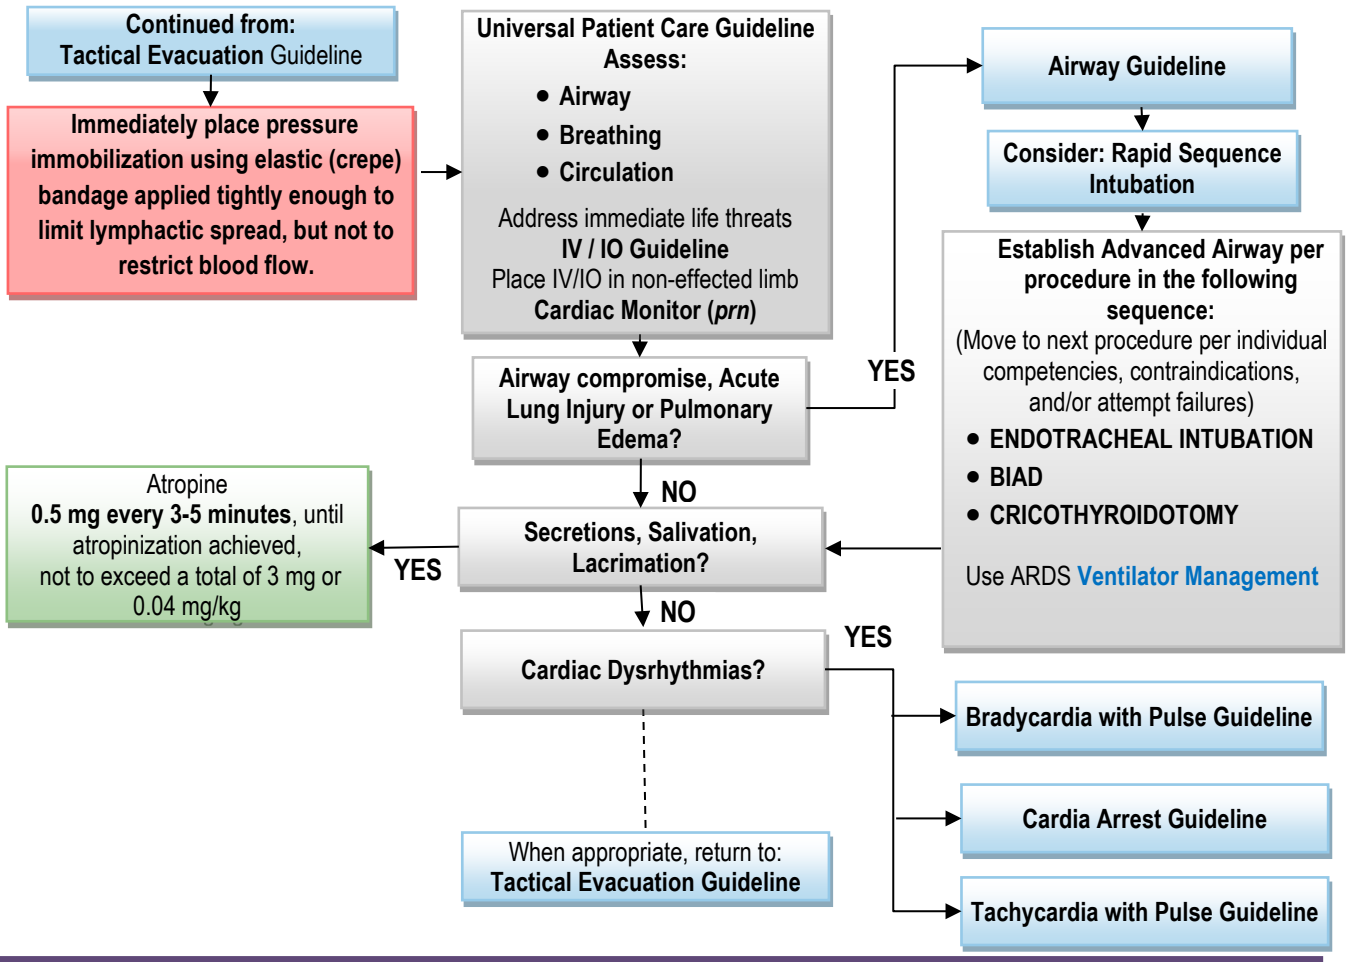


Pearls:

- Review country environmental concerns before deployment or visitation.
- **Anaphylactic reactions should be treated as soon as recognized**.
- Given the low risk of infection, antibiotics are not routinely recommended.
- Depending upon the severity of pain, acetaminophen, nonsteroidal anti-inflammatory agents, and opioids can be used for pain control.
- **Ketamine is not recommended** as patients may develop tachycardia and have profound hypertension due to widow spider toxin.
- Benzodiazepines may improve muscle spasms.
- Pain control and benzodiazepines are often sufficient to manage tachycardia and hypertension.
- Patients with severe pain refractory to pain medications, antivenom (if available) may be indicated, evacuate to MTF where antivenom is available if able.
- Elevate effected limb to reduce swelling.
- ***DO NOT apply constricting bandages or tourniquets*** as these may worsen local tissue injury and increase the risk of permanent disability.
- ***DO NOT*** cut, suck, electrocute, burn, or use chemicals on the envenomation site.

Funnel Web Spider Envenomation

The lethal component of funnel web spider venom is robustotoxin. It induces an autonomic storm by causing excessive release of acetylcholine, norepinephrine, and epinephrine. Funnel web spider envenomation causes a biphasic envenomation syndrome. The first phase includes pain at the bite site, perioral tingling, piloerection, and regional fasciculations which may progress to muscle spasm. This muscle spasm may involve the face, tongue, and larynx leading to airway compromise. The increased stimulation of cholinergic and adrenergic systems causes nausea, vomiting, lacrimation, salivation, tachycardia, hypertension, cardiac dysrhythmias, and acute lung injury. Acute lung injury is the predominate cause of death during the first phase. In the second phase the symptoms of the first phase resolve and lead to the gradual onset of refractory hypotension, apnea, and cardiac arrest.



Continued from: Tactical Evacuation Guideline
Immediately place pressure immobilization using elastic (crepe) bandage applied tightly enough to limit lymphactic spread, but not to restrict blood flow.
Universal Patient Care Guideline
Assess:
Airway
Breathing
Circulation
Address immediate life threats
IV / IO Guideline
Place IV/IO in non-effected limb
Cardiac Monitor (prn)
Airway compromise, Acute Lung Injury or Pulmonary Edema?
YES
Airway Guideline
Consider: Rapid Sequence Intubation
Establish Advanced Airway per procedure in the following sequence:
(Move to next procedure per individual competencies, contraindications, and/or attempt failures)
ENDOTRACHEAL INTUBATION
BIAD
CRICOTHYROIDOTOMY
Use ARDS Ventilator Management
NO
Secretions, Salivation, Lacrimation?
YES
Atropine
0.5 mg every 3-5 minutes, until atropinization achieved,
not to exceed a total of 3 mg or 0.04 mg/kg
NO
Cardiac Dysrhythmias?
YES
Bradycardia with Pulse Guideline
Cardia Arrest Guideline
Tachycardia with Pulse Guideline
When appropriate, return to:
Tactical Evacuation Guideline

Pearls:

- Immediately transport to an MTF with antivenom. Effective funnel web spider antivenom is available in Australia.
- **Anaphylactic reactions should be treated as soon as recognized**.
- Local tissue enzymes may inactivate the venom, therefore the use of pressure immobilization bandage may be helpful in delaying the onset of symptoms, but also may allow for a degree of inactivation of the venom.
- **Ketamine is not recommended** as patients may develop tachycardia and have profound hypertension.
- Benzodiazepines may improve muscle spasms.
- Elevate effected limb to reduce swelling.
- ***DO NOT*** cut, suck, electrocute, burn, or use chemicals on the envenomation site.

Scorpion Envenomation

Pearls:

- **Anaphylactic reactions should be treated as soon as recognized**.
- For clinically significant envenomation, management is supportive and focused on the patient's symptoms and graded 1-4.
- Patients graded 3 & 4 will require antivenom, evacuate to a MTF able to administer antivenom.
- Administer Benzodiazepines aggressively to ensure symptom control.
- For significant neuromuscular spasm, oral secretions, sedation, or other threats to the patent airway, perform endotracheal intubation to prevent aspiration and ensure adequate ventilation.
- Pulmonary edema should be managed with noninvasive or invasive ventilation in combination with optimization of cardiac output
- Direct acting vasopressors(epinephrine and norepinephrine) are recommended to treat bradycardia and hypotension
- Elevate effected limb to reduce swelling.
- ***DO NOT apply constricting bandages or tourniquets*** as these may worsen local tissue injury and increase the risk of permanent disability.
- ***DO NOT*** cut. suck. electrocute. burn. or use chemicals on the envenomation site.

Clinical Grade and Treatment of Scorpion Stings		
Grade	Effects	Treatment
1	Local Effects Only	Analgesia
2	Mild/Moderate autonomic excitation (i.e. tachycardia, hypertension)	Benzodiazepines
	Agitation and anxiety	Benzodiazepines
	Pain and paresthesias remote from the sting site	Analgesia
3	Pulmonary edema	Antivenom, noninvasive or mechanical ventilation
	Hypotension and cardiogenic shock	Antivenom, vasopressors (i.e., norepinephrine, epinephrine)
	Neuromuscular excitation, somatic neuromuscular dysfunction or cranial nerve dysfunction (associated with Centruroides species)	Antivenom, benzodiazepines
4	Multiorgan failure, coma, seizures, end-organ damage secondary to hypotension, somatic neuromuscular dysfunction and cranial nerve dysfunction (associated with Centruroides species)	Antivenom, vasopressors, sedation (benzodiazepine, propofol, phenobarbital), mechanical ventilation

Allergic Reaction / Anaphylaxis

Allergic Reaction Guideline

Airway Compromise

Airway Guideline

Rapid Sequence Intubation

Establish Advanced Airway per procedure in the following sequence:
(Move to next procedure per individual competencies, contraindications, and/or attempt failures)

- **ENDOTRACHEAL INTUBATION**
- **BIAD**
- **CRICOTHYROIDOTOMY**

Pulmonary Edema:
Use ARDS for
Ventilator Management

Analgesia
Consider acetaminophen, NSAIDs, and Opioids:

Acetaminophen
1gram PO prn every 6-8 hours max 4gm in 24 hour period

Ketorolac
15mg IV every 6hr
or **15-30mg IM** every 6hr,
max daily dose 120mg

Fentanyl
0.5 – 1.0 mcg/kg IV/IO
100 mcg IN
May repeat every 30 min
or
PO 800mcg OTFC

Increased Secretions / Salivation/ Lacrimation

Atropine
0.5 mg every 3-5 minutes, until atropinization achieved, not to exceed a total of 3 mg or 0.04 mg/kg

Benzodiazepines

Midazolam 2.5-5mg IV / IO every 15-30 prn
or
Diazepam
5-10 mg IV/IO; then 5-10 mg in 3-4 hours, if necessary

Hypotension / Cardiogenic Shock: Vasopressors

HYPOTENSION / SHOCK GUIDELINE

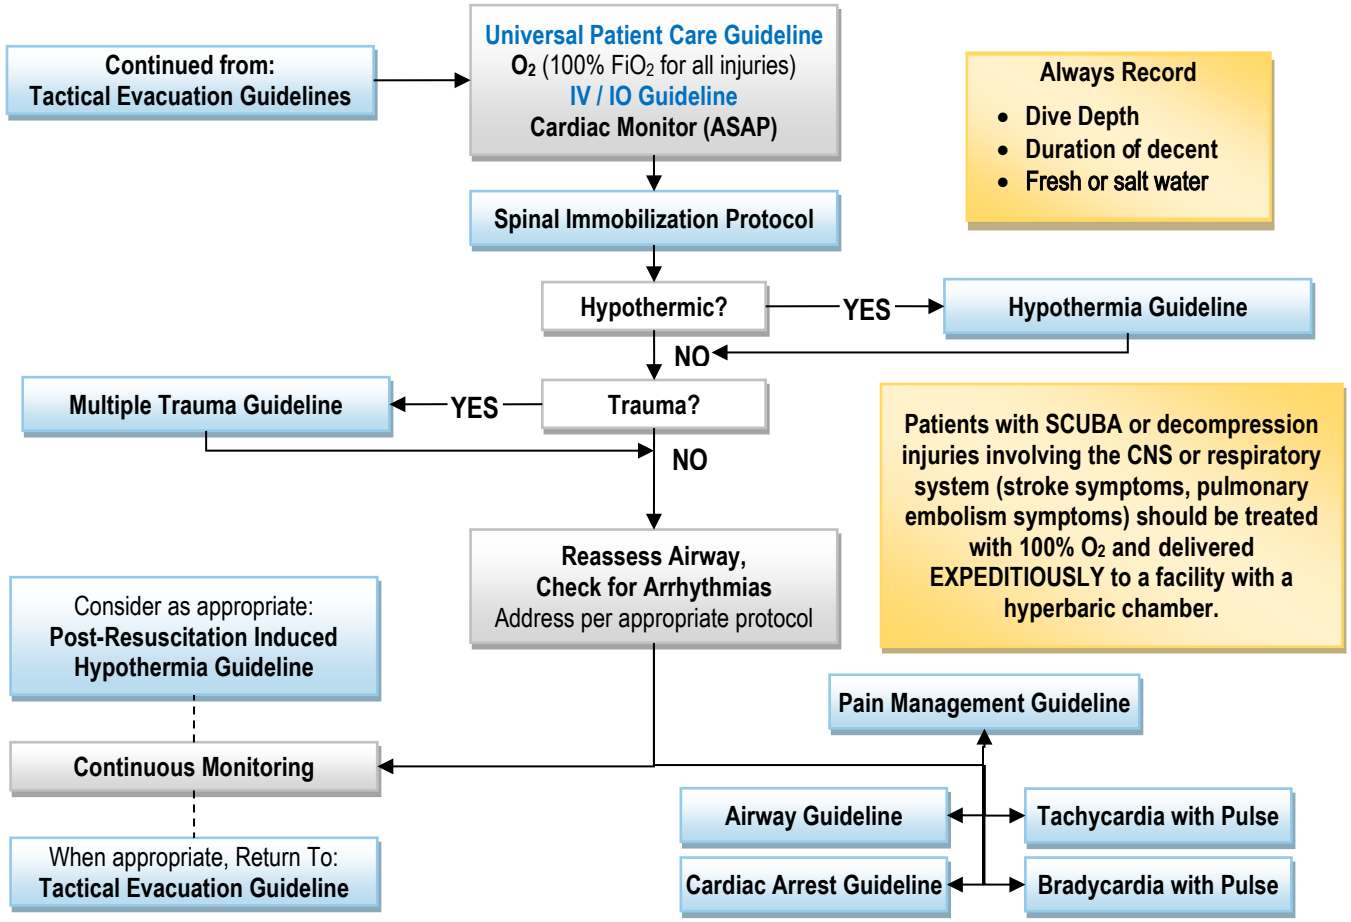
Norepinephrine
2-20mcg/min IV/IO, titrate to effect
(See **Norepinephrine Infusion Chart**)
or
Epinephrine 1mg/10ml
5-20 mcg IV/IO Push; may repeat ONCE in 2-5 minutes.
If patient remains hypotensive, proceed to continuous infusion.

2-10 mcg/minute; titrate to desired effect
(See **Epinephrine 1mg/10ml Infusion Chart**)

SUBMERSION INJURY

Signs and Symptoms:
- **Unresponsive**
- **Mental Status Changes**
- **Hypoxia**
- **Cyanosis**
- **Hypothermia**
- **Vomiting**
- **Coughing**

Differential Diagnosis:
- **Trauma (esp. C-spine)**
- **Dysbarism**
- **Pressure Injury as in Self-contained under water breathing apparatus (SCUBA)**



Pearls:
- If Decompression Illness or arterial gas embolism is suspected and neurological deficits (including altered mental status) are present, consider high-flow oxygen, lidocaine 1.5 mg/kg IV / IO, and aspirin 325mg. While these interventions remain unproven, the risk / benefit ratio makes them acceptable options, particularly if time to hyperbaric chamber is anticipated to be prolonged.
- Rapid hypothermia from cold water immersion in children has resulted in survival despite prolonged downtime – resuscitate per appropriate protocols and rapidly transport. This has not been seen in adults.
- All near-drowning victims should be transported for evaluation due to potential for worsening respiratory status over next several hours.
- Drowning is the leading cause of death among would-be rescuers.
- Head-first diving injuries often associated with unstable Jefferson fracture (burst fracture of C1) due to axial load. Patients found with suspicion of this type of injury should have early and careful C-spine immobilization.
- Altitude should be restricted in patients suffering from decompression illnesses to prevent worsening. Should remain <1000 ft. AGL / 10,000 ft. MSL whenever possible.
    - Aggressive pre-planning for access to hyperbaric treatment facilities is encouraged if mission requirements warrant it.

CBRN CASUALTY MANAGEMENT

BASIC PRINCIPLES:

Initial care of the CBRN casualty should be approached in the same manner as other casualties. Life threats require prompt recognition and intervention, and non-life-threatening sequelae can be addressed when clinically appropriate. Early recognition and categorization of CBRN-exposed patients is the foundation for further management, and is key not only for initiating patient treatment but also for preventing contamination of medical personnel, equipment, and facilities. Thorough and appropriate decontamination is a core skill that requires planning and practice. Attention to details such as preventing hypothermia in patients undergoing decontamination and clinical reassessment at each stage of the process will reduce unnecessary morbidity. Basic life saving measures such as airway management and resuscitation are fundamental concepts that must be mastered at the appropriate level for each practitioner in the CBRN care chain.

CBRN CRITICAL TASK LIST:

1. Recognize CBRN exposure that requires action to protect self and others.
2. Don personal protective equipment (PPE) to prevent exposure in self and assist others with PPE.
3. Egress from the threat:
    a. Move upwind, uphill, upstream from threat.
    b. Utilize time/distance/shielding for protection.
4. Recognize signs/symptoms of CBRN exposure that prompt immediate self-treatment or treatment of others utilizing CRESS assessment. (RAPID IDENTIFICATION OF CHEMICAL WARFARE AGENTS).
5. Apply TCCC integrated with CBRN response [TCCC + CBRN = (MARCHE)^2]. (MARCHE^2)
6. Apply airway management skills in a CBRN setting (positioning, suction, ventilation to include manual.
7. Perform Rapid Spot Decontamination.
8. Identify and establish Hot/Warm/Cold Zones.
9. Establish a dirty casualty collection point (CCP).
10. Understand decontamination principles and casualty procedures for partial or complete removal of PPE, clothing, and equipment (casualty cut out).
11. Understand cross contamination and take appropriate measures to prevent it.
12. Understand available technology that can aid in agent identification.

CBRN MEDICAL REGULATING CONSIDERATIONS:

1. Military Treatment Facility (MTF).
    a. DECON/Treatment Coordination. Ensure MTF is prepared to receive dirty casualties and determine the most appropriate location for DECON.
    b. Treatment Capabilities (Toxicology, Critical Care, Trauma Surgery). Determine whether the MTF has the services necessary to care for and sustain the CBRN casualty on site and/or establish telemedicine support.
    c. Capacity. The CBRN casualty is far more resource intensive than a typical trauma or critically ill casualty. Assess the MTF's capacity and capability to treat CBRN casualties and identify potential alternate locations.
2. Integrate the medical regulating system into CBRN casualty evacuation.

EVACUATION PLATFORM CONSIDERATIONS:

1. Evacuation of patients must continue even in a contaminated environment.
2. Clean and Dirty. It is necessary to plan for both clean and dirty platforms for evacuation.
    a. Optimize the use of resources, medical or nonmedical, which are already contaminated before employing uncontaminated resources.
    b. Once a vehicle or aircraft has entered a contaminated area, it is highly unlikely that it will be able to be spared long enough to undergo a complete decontamination. Factors include - contaminant, the tempo of the battle, and the resources available.
    c. Contaminated vehicles (air and ground) will have restricted use and are confined to a contaminated environment until decontamination can occur.
3. Refuel.
    a. Consider the time it takes for refueling in a MASCAL situation, as well as the distance from the objective to the DECON site and MTF.
    b. Factor in any platform decontamination that may be necessary prior to arrival at the refueling site.
    c. WARM ZONE Forward Arming and Refuel Points may be necessary.
4. Preparation time (hasty vs. deliberate). Factor the time it takes to prepare the platform for a hasty or deliberate CBRN mission.
5. Radiological Exposure Limitations:
    a. Operational exposure guidance: MEDEVAC operations will establish operational exposure guidelines by the appropriate Surgeon and Command limiting radiation exposure to crews by absorbed dosage.
    b. Radiation exposure records are maintained by the unit CBRN noncommissioned officer and are made available to the commander, staff, and surgeon.
6. Flying Hour Limitations:
    a. Environmental Relative Factors (ERF) under Mission Oriented Protective Posture (MOPP) 3 and 4 limits flying hours to 3 hours day, night or combined modes of flight.
    b. ERF extensions are limited to a case by case basis.

CBRN LANDING ZONES / AMBULANCE (CASUALTY) EXHCHANGE POINTS:

1. Route coordination. Consider alternate routes, primary routes may be jammed or unavailable.
2. Consider appropriate distance to accommodate for aircraft rotor wash and direction of landing for Dirty LZs and Clean LZs at the DECON/CCP locations.
3. Environmental Considerations:
    a. Wind
    b. Terrain / Slope
    c. Drainage (for DECON Sites)
    d. Water Sources

CBRN MILITARY WORKING DOG CASUALTY MANAGEMENT

Chemical protective doctrine for animals is incomplete, and there is no chemical protective equipment in the current inventory for MWDs. Equipment and doctrine for animals are under development but pending its availability, any degree of protection of the MWD in a CBRN agent environment will, at best, be extremely difficult. The MWD's Handler should be in possession of additional ATNAA and CANA kits to use on their MWD. Attempt to obtain and use those resources first when treating a MWD.

MILITARY WORKING DOG DECONTAMINATION PROCEDURES

While not generally a MEDEVAC mission, ensuring proper MWD Decon prior to transport is vital to ensuring the platform and crew are not contaminated by the agent involved.

- Rinse the MWD thoroughly with plain water beginning at the head along the back and to the tail; then rinse down the MWD's sides, chest, stomach, legs, and paws.
- Work the soap into the hair starting the head, along the back and to the tip of the tail, then work down the MWD's sides, chest, and abdomen, legs, and paws. Ensure the soap reaches the MWD's skin. If the MWD has erect ears, flush the ears with otic solution or water.

Note. Special attention should be paid to the MWD's stomach, face, ears, eyes, under tail, paws and in between legs to ensure all contamination is removed.

- Flushed the eyes with copious amounts of water, ophthalmic solution, or saline.
- Rinse with plain water using the same pattern as the initial rinse (head to back to tail, then down sides, chest, stomach, legs, and paws).
- Allow the MWD to shake off excess water. A tarp or other impervious materiel may be placed around the MWD while it shakes off excess water to prevent contaminating of other people, MWDs, or equipment.

TREATMENT OF MILITARY WORKING DOG CASUALTIES OF NERVE AGENTS

- For mildly exposed MWDs, administer a total of two ATNAA injections (atropine and 2-PAM Cl in a single autoinjector) (carried by the MWD handler) into the back of the thigh of the dog. The initial dosage of atropine is 4 mg and the dosage for 2-PAM Cl is 1200 mg

- For severely exposed MWDs, administer three ATNAA and one CANA. This is similar to the buddy aid a Service member provides another Service member suffering from severe nerve agent exposure. In general, MWDs should not need additional 2-PAM Cl injections.

- Single atropine injections may be given every 10 to 20 minutes until the nerve agent effects have subsided or signs of atropinization appear. The MWD must be monitored for heat stress. Atropine dries the mucous membranes thus preventing the MWD from expelling body heat.

- The initial dosage of 2-PAM Cl in the dog is 20 mg/kilogram. Three ATNAA injectors should provide sufficient amount of 2-PAM Cl. If a MWD is still showing signs of seizure after initial

treatment, the handler may give up to 3 additional CANA autoinjections at 5 to 10 minute intervals until the seizures are gone.

- Maintain a clear airway by removing respiratory secretions and saliva obstructing the airway. Loosen or remove the muzzle. In severe nerve agent exposure, the animal's respiration is markedly depressed and extreme muscular weakness or paralysis is present. In such cases, assisted ventilation is required to effectively resuscitate the animal.

Adequate atropine and 2-PAM Cl should bring about an improvement or restoration of spontaneous respiration and also improve blood circulation. However, the effectiveness of 2-PAM Cl is lost after a short period of time. The 2-PAM Cl varies in its effectiveness against nerve agents. It is least effective against GD nerve agent. In some cases, severe nerve agent symptoms may persist or recur and require veterinary personnel to administer additional 2-PAM Cl autoinjectors every 8 to 12 hours for up to 3 days.

MARCHE^2

After initial assessment of casualty in CBRN-threat environment for the presence or absence of CBRN symptoms using the CRESS algorithm, the integrated assessment and management of TCCC and CBRN injuries can proceed. MARCHE^2 integrates the TCCC MARCH algorithm with the priorities of CBRN treatment. MARCHE^2 is further broken down into phases similar to TCCC. The "Hot Zone" should be considered as care under fire, addressing only immediate life threats, "Warm Zone" is tactical field care and "Cold Zone" as tactical evacuation care.

MARCHE^2 Algorithm

TCCC MARCH

MASSIVE HEMORHORAGE

- HASTY tourniquets in the HOT ZONE
- Transition to DELIBERATE tourniquets during DECON in WARM ZONE

AIRWAY

- Assess – excessive secretions indicate **NERVE AGENT**
- Defer most interventions - consider risks in active HOT ZONE of remove mask to access airway

Respirations

- Increased respirations consider **ATNAA/CANA NERVE AGENT GUIDELINE**
- Depressed respirations consider **NAXOLONE INCAPACITATING AGENT GUIDELINE**
- Other than antidotes – respiratory interventions is best deferred to WARM ZONE

Circulation

- Circulation intervention should be deferred to WARM ZONE
- Assess for shock
- **IV/IO GUIDELINE**
- **HYPOTENSION/SHOCK GUIDELINE**

CRESS Assessment

Consciousness:
Conscious, Unconscious, depressed consciousness, AMS, seizures, agitation, normal

Respirations:
Normal, increased, decreased, distress, delayed onset, apneic, tachypnea, wheezing, immediate irritation

Eyes:
Normal, constricted (Miosis), dilated (Mydriasis), irritated, painful,

Secretions:
None, Increased, Decreased Copious Secretions (salivation, lacrimation, rhinorrrhea, bronchorrhea),

Skin:
Normal, Dry and Hot, Flushed, Erythema, Diaphoresis, Cyanotic, Blisters, Pain

CRESS must be reassessed regularly, during zone transitions and at each transfer, to monitor for delayed onset of life threatening symptoms, and analyze antidote or countermeasure effectiveness

CBRN MARCHE^2

Mask

- MASK or CHECK MASK SEAL as immediate HOT ZONE treatment

Antidote

- Utilize CRESS to differentiate chemical agent exposure **RAPID IDENTIFICATION OF CHEMICAL WARFARE AGENT**
- **ATNAA** (x3)/**CANA** (x1) for **NERVE AGENT**
- **NAXOLONE** (2mg IM) for OPIOID **INCAPATICITATING AGENT**
- Can consider **Cyanokit®** in HOT ZONE for **BLOOD AGENT** if symptoms are severe, first action should be removal from area of exposure and rapid spot decontamination

Rapid Spot Decontamination

- Indicated for gross contamination on skin and/or wounds or if protective gear is breached
- Rapid exposure and decontamination of contaminated wounds is necessary lifesaving procedure in the HOT ZONE
- Apply RSDL, M100, M295, Sorbent, tech wipe, etc.

Countermeasures

- Appropriate therapy based on type of agent exposure, post initial antidote administration
- Deferred to WARM ZONE

Hypothermia Prevention & Head Injury

- Protect from lethal triad: **HYPOTHERMIA**, acidosis and coagulopathy through HOT/WARM/COLD ZONES
- Active warming or HPMK post decontamination and packaging for further evacuation
- Determine if altered mental status is due to chemical agent or trauma, if trauma **HEAD INJURY/TBI GUIDLINE**

Extricate and Evacuate

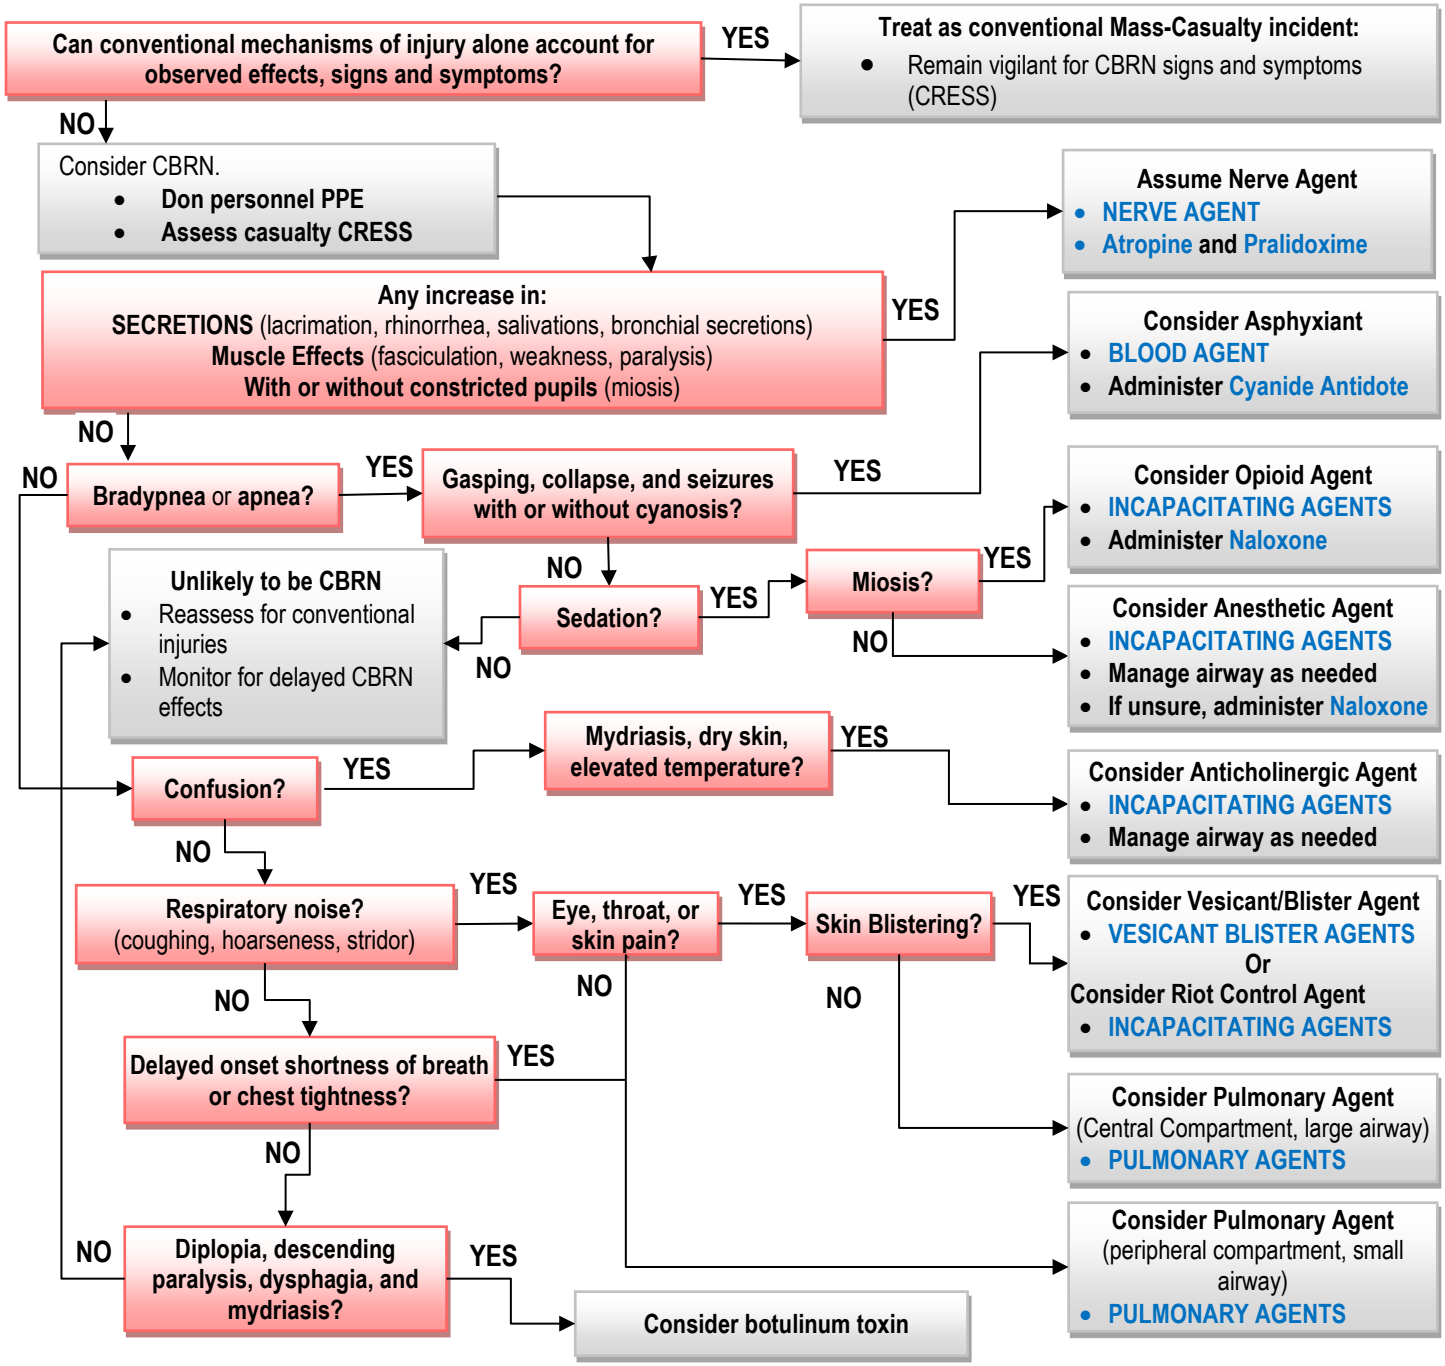
- EXTRICATE: egress patient from threat, agent contact, HOT ZONE
- Evacuate: to WARM ZONE – Dirty CCP for decontamination
- COUNTERMEASURES and appropriate supportive care starts in WARM ZONE and continues during Evacuation/COLD ZONE

Pearls:

- Treatment goals of CBRN is give antidote, extricate from exposure area, conduct spot decontamination, provide airway support.

RAPID IDENTIFICATION OF CHEMICAL-WAFARE AGENTS

Assess:	Observations:
C- Consciousness	• unconscious, seizures, depressed consciousness, agitation
R- Respirations	• present, absent, labored, increased, decreased, normal, abnormal
E- Eyes	• constricted, dilated, normal
S- Secretions	• dry, normal, increased
S- Skin	• diaphoretic, dry, hot, cyanosis



Pearls:

- Treatment goals of CBRN is give anti-dote, provide airway support, conduct spot decontamination.

NERVE AGENT

Nerve Agent
- Liquid or Vapor
- Non-Persistent (GA, GB, GF)
- Persistent (VX)
- Organophosphate Treatment

PPE and Detection
- Mask
- AP-PPE
- JLIST or UIPE

M8 Detection Paper
- G – Yellow
- V – Green

CRESS Symptomatic Presentation
C: altered, unconscious, seizures
R: tachypnea, wheezing, respiratory distress
E: miosis (may or may not be present with organophosphate)
S: copious secretions (salivation, lacrimation bronchorrhea)
S: diaphoresis

HOT ZONE
POI

Immediate Action + M², A², R², E.
- address **MASSIVE HEMORRHAGE / Mask check**
- assess **AIRWAY** / administer **ANTIDOTE**
- asses **RESPIRATIONS** / conduct **RAPID SPOT DECON**
- **Extract** (move upwind, uphill, upstream – away from threat)

NERVE AGENT ANTIDOTE
Antidote Treatment, Nerve Agent, Auto-Injector (ATNAA)
- **ATNAA** contains **2.1mg Atropine** and **600mg Pralidoxime Cholride (2PAM)** in each Auto Injector
- Initial administration is **3x ATNAA** in rapid sequence for sever signs of nerve agent poisoning **(6.3mg Atropine, 1800mg 2PAM)**

Convulsant Antidote Nerve Agent (CANA)
- **CANA** contains **10mg Diazepam**
- Administer **1x CANA** following **3x ATNAA**

WARM ZONE
DIRTY CCP

M², A², R², Reassement (clear airway, O² as needed, filtered air)
- Decontaminate and Cutout

C², H², E
- **CIRCULATION** (asses vitals, resuscitate) administer **COUNTERMEASURES** as necessary if **ATNAA/CANA** administered and symptoms persist
- Prevent **HYPOTHERMIA** / assess mental status (altered due to agent or trauma?) **HEAD INJURY**
- **EVACUATE** to next role of care/zone

NERVE AGENT COUNTERMEASURES
ATROPINE IV/IO
- 20mg in 250mL NS IV/IO, titrate 1mg every 3 mins to dry secretions
- Once clinical improvement achieved, adjust to rate of 2-4mg/hr

PRALIDOXIME IV/IO
- 1-2gm in 250mL NS IV/IO over 15-30min.

BENZODIAZEPINES IV/IO
- **MIDAZOLAM** (preferred)1-2mg IV/IO, titrate to effect
- **DIAZEPAM** 10-20mg IV/IO, titrate to effect

SCOPOLAMINE IV/IM (adjunct if available)
- 0.8mg IV/IM

COLD ZONE

MARCHE² Reassessment
- Continue to address any immediate life threats
- provide **AIRWAY** and **RESPIRATORY** support as necessary
- continue **CIRCULATION** support / **COUNTERMEASURES** as symptoms dictate
- prevent **HYPOTHERMIA** with HPMK, warm fluids / **HEAD INJURY** treat elevated ICP, conduct neuro exam, MACE

Reassess regularly, follow protocols for respiratory or cardiac compromise.

BLOOD AGENT - CYANIDE

Blood Agent – Cyanide
- Hydrogen Cyanide, Cyanogen Chloride
- volatile water-soluble liquid
- vapor
- Odor: Bitter Almonds

PPE and Detection
- Mask
- AP-PPE
- JLIST or UIPE

M8 Detection Paper
- Does not detect

CRESS Symptomatic Presentation
C: altered or unconscious
R: normal to apneic
E: normal unless vapor irritant
S: none
S: may appear flushed (50% occurrence)

HOT ZONE
POI

Immediate Action + M², A², R², E.
- address **MASSIVE HEMORRHAGE / Mask check**
- assess **AIRWAY** / administer **ANTIDOTE**
- asses **RESPIRATIONS** / conduct **RAPID SPOT DECON**
- **Extract** (move upwind, uphill, upstream – away from threat)

CYANIDE ANTIDOTE
HYDROXOCOBALAMIN (Cyanokit®) IV/IO
- **5gm IV/IO over 5min with 200ml NS or LR or D5W**
- Do not shake vial (gently mix)
- Do not use if solution is not dark red
- Reapeat second 5gm dose based on severity and clinical response
- Maximum cumalitive dose 10gm

Antidote Considerations:
Decision to give in hot or warm zone is based on clinical presentation. Unlikely to have diagnostic adjuncts (lactate, arterial/venous samples) prior to cold zone. High concentrations of cyanide can result in death within seconds to minutes. Early symptoms may include dizziness, headache, weakness, diaphoresis, and dyspnea / hyperpnea. CNS and cardiotoxicity occur due to intracellular hypoxia.
- **Consider amyl nitrite (0.3mL ampule)**
- If Cyanokit® (hydroxocobalamin) antidote is not available, aggressive supportive care may be sufficient treatment.

WARM ZONE
DIRTY CCP

M², A², R², Reassement (clear airway, O^2 as needed, filtered air)
Decontaminate and Cutout
- Remove and bag equipment, PPE, and clothing
- Evacuation from exposure + clothing removal is adequate decon
- Can further decontaminate skin with irritation solution, but priority is antidote

C², H², E
- **CIRCULATION** (asses vitals, resuscitate) administer **COUNTERMEASURES** (initial or second **Cyanokit®**)
- Prevent **HYPOTHERMIA** / assess mental status (altered due to agent or trauma?) **HEAD INJURY**
- **EVACUATE** to next role of care/zone

COLD ZONE

MARCHE² Reassessment
- Continue to address any immediate life threats
- provide **AIRWAY** and **RESPIRATORY** support as necessary, provide **supplemental O_2** even with normal SPO_2
- continue **CIRCULATION** (monitor)t / **COUNTERMEASURES** 2nd dose as appropriate)
- prevent **HYPOTHERMIA** with HPMK, warm fluids / **HEAD INJURY** treat elevated ICP, conduct neuro exam, MACE

Anticipate hemodynamic compromise, seizures, cardiac arrhythmiasReassess regularly, follow protocols for respiratory or cardiac compromise.

PULMONARY AGENTS

Pulmonary Agents: Phosgene, Chlorine

- Phosgene, Chlorine
- Gas ($COCL_2$) above 47°F/8.3°C
- Gas (Cl) above 29°F/-1.6°C
- Odor Phosgene: freshly mowed hay
- Phosgene toxic below odor threshold

PPE and Detection

- Mask (C2-A1 Filter)
- AP-PPE
- JLIST or UIPE

M8 Detection Paper

- Not effective

CRESS Symptomatic Presentation

C: conscious (unconscious if asphyxia)
R: normal to respiratory distress, delayed onset up to 24 hours (phosgene)
E: irritated, injected (chlorine)
S: Mucous membrane irritation (rhinorrhea, salivation)
S: Chlorine: immediate irritation (tearing and rhinorrhea) Phosgene: delayed fluid buildup

HOT ZONE
POI

Immediate Action + M², A², R², E.

- address **MASSIVE HEMORRHAGE / Mask check**
- assess **AIRWAY** / administer **ANTIDOTE**
- asses **RESPIRATIONS** / conduct **RAPID SPOT DECON**
- **Extract** (move upwind, uphill, upstream – away from threat)

WARM ZONE
DIRTY CCP

M², A², R², Reassement (

- Clear airway (copious secretions)
- Anticipate laryngospasms
- Place advanced airway (largest bore ET as able), be prepare to conduct cricothyroidotomy for failed airway
- Advanced Ventilatory support (SAVe or simple vent may not be sufficient, ARDS technique, need to manipulate peep, volume, FIO2)
- O_2 as needed, maintain air filter

Decontaminate and Cutout

- Remove and bag equipment, PPE, and clothing
- Soap and water sufficient for skin decon
- Remove and replace contaminated treatments (chest seals, tourniquets, etc.)

C², H², E

- **CIRCULATION** (asses vitals) **COUNTERMEASURES**
- Prevent **HYPOTHERMIA** / assess mental status (altered due to agent or trauma?) **HEAD INJURY**
- **EVACUATE** to next role of care/zone

COLD ZONE

MARCHE² Reassessment

- Continue to address any immediate life threats
- provide **AIRWAY** and **RESPIRATORY** support as necessary, provide **supplemental O_2** even with normal SPO_2
- continue **CIRCULATION** support (monitor vitals), resuscitate as necessary / **COUNTERMEASURES** 2nd dose as appropriate)
- prevent **HYPOTHERMIA** with HPMK, warm fluids / **HEAD INJURY** treat elevated ICP, conduct neuro exam, MACE

There is no antidote for Chlorine or Phosgene exposure. Treatment focus is remove from exposure, aggressive management of airway and respirations, supportive care.

PHOSGENE: Onset of symptoms can be delayed up to 24 hours, generally 2-6 hours after exposure. Exertion is associated with worse outcomes, so keep patients exposed to phosgene at rest. The major effects of phosgene are on peripheral airways, therefore dyspnea, chest tightness or pain, and cough are common symptoms. Development of hypoxia and pulmonary edema. Fluid shifts secondary to pulmonary edema may result in hypovolemia.

Chlorine: Onset of symptoms are immediate. Chlorine causes more immediate symptoms in the moist areas of the eyes, mouth, and upper airways. Eye pain, blepharospasm, and lacrimation are common. Other symptoms may include headache, salivation, dyspnea, cough, hemoptysis, chest burning, and vomiting. Irrigate eyes if irritated or burning.

Laryngospasm may occur with both Phosgene and Chlorine. Anticipate airway edema and manage airway early. If advanced airway required, place largest endotracheal tube possible to facilitate suctioning. Intravenous fluids may be necessary in the setting of volume depletion, but should not be given empirically. Fluid overload can contribute to pulmonary edema and should be avoided.

Consider following for wheezing /bronchospasms:

- **ALBUTEROL (2.5mg in 3ml NS)**
- **METHYPREDNISOLONE (125mg IV)**
- **See RESPIRATORY DISTRESS**

Mechanical Ventilations

- Use **ARDS VENTILATOR MANAGEMENT** techniques

VESICANT BLISTER AGENTS

Vesicant Agents: Anticholinergics, Opioids, Riot Control
- Lewisite (L), Mustard-Lewisite Mixture (HL)
- Immediate Acting Agent
- Oily liquid
- Persistent, Freezing 0.4°F/-17°C
- Odors: Geraniums

PPE and Detection
- Mask
- AP-PPE
- JLIST or UIPE

M8 Detection Paper
- Red to Pink

LCD Detection
- Red or Orange H

CRESS Symptomatic Presentation
C: Conscious (unconscious due to other effects)
R: Immediate irritation, distress
E: Immediate severe pain, blepharospasm edema
S: Normal to increased
S: Immediate pain, erythema, blisters form hours later
OTHER: Systemic effects – distributive shock

HOT ZONE
POI

Immediate Action + M², A², R², E.
- address MASSIVE HEMORRHAGE / **Mask check**
- assess AIRWAY / administer **ANTIDOTE (none in HOT ZONE)**
- asses **RESPIRATIONS** / conduct **RAPID SPOT DECON**
- **Extract** (move upwind, uphill, upstream – away from threat) Extraction to the Dirty CCP [For Small Spills (< 2 kg) move away 100m day/300m night] [Large Spills (< 25kg) = 500m day/1000m night]

WARM ZONE
DIRTY CCP

M², A², R², Reassessment
- Clear airway, O_2 as needed, maintain filtered air
- ALBUTEROL **(2.5mg in 3ml NS)**
- Invasive airway if unresponsive to albuterol

Decontaminate and Cutout
- Remove and bag equipment, PPE, and clothing
- Wipe away gross contamination, RSDL cut line, cut out
- RSDL residual contamination on skin (>2min contact time, then wipe away)
- Remove and replace contaminated treatments (chest seals, tourniquets, etc.)

C², H², E
- **CIRCULATION** (asses vitals, resuscitate) **COUNTERMEASURES** (rapid decon, irrigate eyes and wounds with water)
- Prevent **HYPOTHERMIA** / assess mental status (altered due to agent or trauma?) HEAD INJURY
- **EVACUATE** to next role of care/zone

COLD ZONE

(MARCHE)² Reassessment
M²: Convert tourniquets & bandage wounds
A²: In case of severe inhalation symptoms upgrade airway adjunct & RSI
R²: Vesicant Inhalation Tx SOP, Ventilator, O2 , PEEP, Suction, Bronchoscopy
C²: Trend Vitals, TXA, FDP, FWB, Fluid Challenge if Req'd / severe exposures will present with distributive shock requiring chelation therapy with Dimercaprol aka British Anti-Lewisite (BAL) in order to resolve
- **H2:** Hypothermia (HPMK, fluid warmer) / Head wounds (treat elevated ICP, Neuro exam, MACE) **HEAD INJURY** treat elevated ICP, conduct neuro exam, MACE

Lewisite binds to tissues and absorbs systemically within two minutes of contact. Symptoms begin to manifest immediately upon exposure and worsen over time. Control of massive hemorrhage and rapid spot decon are top priorities.

Casualties with palm-size exposure without rapid decon, >5% BSA burn, pulmonary edema, or shock symptoms with rapid onset require chelation. Early pain control may be required to ensure casualty cooperation. Administration of BAL within 5 minutes of exposure to skin and eyes can neutralize agent.

COUNTERMEASURE / TREATMENT
Dimercaprol (BAL) Administration
- Initial Dose: 3 mg/kg deep IM repeat every 4 hours for two days
- Then: Every 12 hours for 7-10 days
- Severe & Life Threating Exposure: consider 5 mg/kg
- Side Effects: Increased BP, Tachycardia, Nausea/vomiting, Headache, Anxiety, Injection Necrosis
- Contraindications: Nut Allergy.

Supportive Care
- PAIN MANAGEMENT
- Expect **SIRS** and **ARDS** in severe cases

Mechanical Ventilations
- Use **ARDS** VENTILATOR MANAGEMENT techniques

Skin
- Burns-apply Silvadene & bandage QID (burn fluid resuscitation not necessary
- Blister fluid may contain Arsenic, unroof >2cm, irrigate, calamine or steroidal cream

Eyes
- Petroleum based ophthalmic ointment,

INCAPACITATING AGENTS

Incapacitating Agents: Anticholinergics, Opioids, Riot Control
- Variable; aerosol, smoke/gas, or liquid
- Fentanyl derivatives extremely potent lethality

PPE and Detection
- Mask (C2-A1 Filter)
- AP-PPE
- JLIST or UIPE

M8 Detection Paper
- Not effective

CRESS Symptomatic Presentation
C: Varies with agents

E:
S:
S:

HOT ZONE
POI

Immediate Action + M², A², R², E.
- address MASSIVE HEMORRHAGE / **Mask check**
- assess AIRWAY / administer **ANTIDOTE**
- asses **RESPIRATIONS** / conduct **RAPID SPOT DECON**
- **Extract** (move upwind, uphill, upstream – away from threat)

WARM ZONE
DIRTY CCP

M², A², R², Reassessment
- Clear airway (copious secretions)
- Anticipate laryngospasms
- Place advanced airway (largest bore ET as able), be prepare to conduct cricothyroidotomy for failed airway
- Advanced Ventilatory support (SAVe or simple vent may not be sufficient, ARDS technique, need to manipulate peep, volume, FIO2)
- O_2 as needed, maintain air filter

Decontaminate and Cutout
- Remove and bag equipment, PPE, and clothing
- Soap and water sufficient for skin decon
- Remove and replace contaminated treatments (chest seals, tourniquets, etc.)

C², H², E
- **CIRCULATION** (asses vitals) **COUNTERMEASURES**
- Prevent **HYPOTHERMIA** / assess mental status (altered due to agent or trauma?) HEAD INJURY
- **EVACUATE** to next role of care/zone

COLD ZONE

MARCHE² Reassessment
- Continue to address any immediate life threats
- provide **AIRWAY** and **RESPIRATORY** support as necessary, provide **supplemental O_2** even with normal SPO_2
- continue **CIRCULATION** support (monitor vitals), resuscitate as necessary / **COUNTERMEASURES** 2nd dose as appropriate)
- prevent **HYPOTHERMIA** with HPMK, warm fluids / **HEAD INJURY** treat elevated ICP, conduct neuro exam, MACE

OPOIDS
C – Sedation
R – Decreased respirations
E - miosis
S – normal
S- normal

OPIOID ANTIDOTE:
- NAXOLONE **(2-4mg)** additional escalating doses up to10mg dose as needed
- May require NAXOLONE drip at 2/3 of response dose/hr
- Support respirations as needed see RESPIRATORY DISTRESS

ANTICHOLINERGICS
C – Delirium, agitation
R – normal, tachypnea, tachycardia
E - red
S – mydriasis
S- red, hot dry

ANTICHOLINERGICS ANTIDOTE:
- Titrate Benzodiazepines **(2-4mg IV/IO/IM)** to control severe agitation
- Support respirations as needed see RESPIRATORY DISTRESS

Laryngospasm may occur with both Phosgene and Chlorine. Anticipate airway edema and manage airway early. If advanced airway required, place largest endotracheal tube possible to facilitate suctioning. Intravenous fluids may be necessary in the setting of volume depletion, but should not be given empirically. Fluid overload can contribute to pulmonary edema and should be avoided.

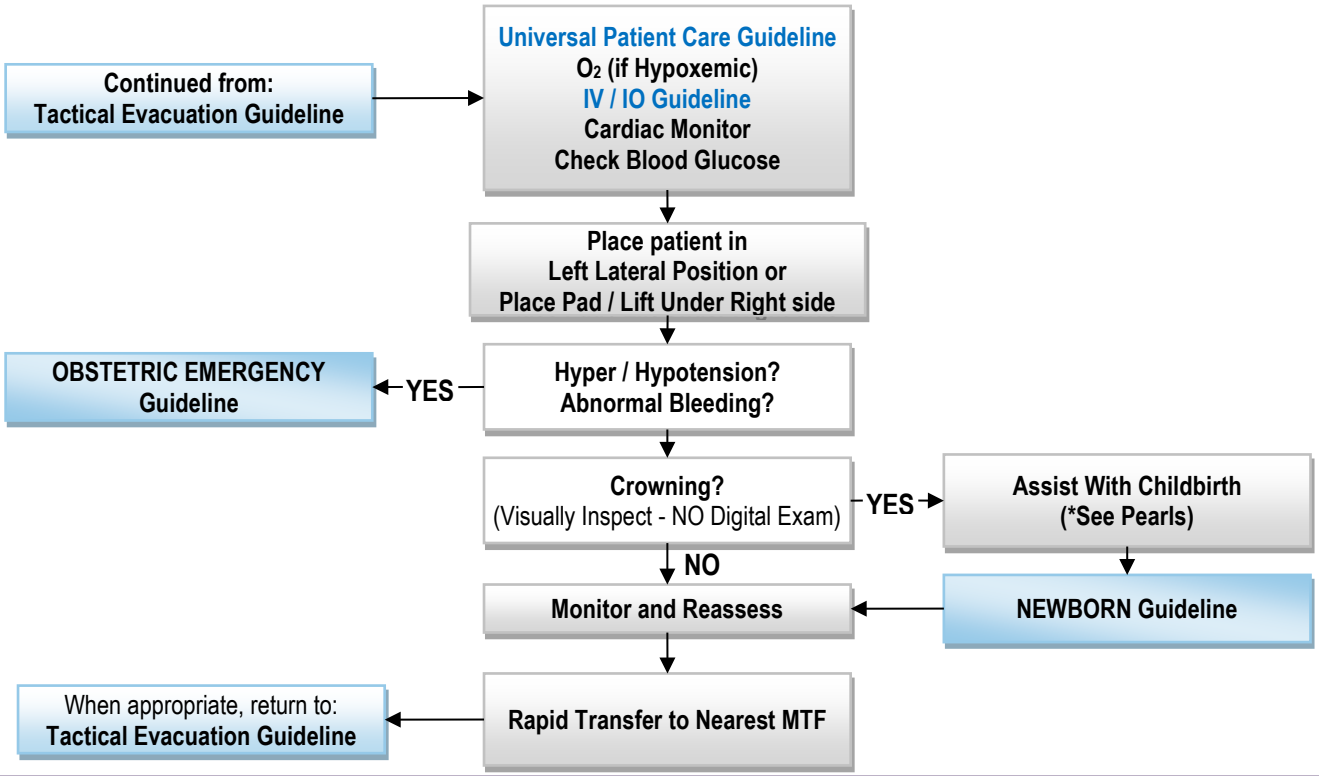
Consider following for wheezing /bronchospasms:
- ALBUTEROL **(2.5mg in 3ml NS)**
- METHYPREDNISOLONE **(125mg IV)**
- **See** RESPIRATORY DISTRESS

Mechanical Ventilations
- Use **ARDS** VENTILATOR MANAGEMENT techniques

CHILD BIRTH

Signs and Symptoms:
- **Spasmodic Pain**
- **Vaginal Fluid / Bleeding**
- **Crowning / Urge to Push**
- **Meconium**

Possible Complications:
- **Preterm Labor**
- **Spontaneous Vaginal Delivery**
- **Placenta Previa**
- **Prolapsed Cord**
- **Abnormal Presentation (e.g., breech)**



Pearls:

- Document all times – delivery, contraction frequency / length.
- Assist with birth:
  - Position mother as necessary.
  - Prepare 2 sets of hemostats and scissors / scalpel, umbilical cord clamp if available, bulb suction.
  - If umbilical cord palpable around neck– attempt to reduce manually prior to delivery of head (should feel rope-like structure around neck). As last resort, and if unable to keep pressure off of the cord, clamp and cut cord when unable to manually reduce.
  - If umbilical cord seen, elevation of presenting part with vaginal hand and maintain elevation until delivery via C-section AKA “ride the bed” ***Do not place pressure on the cord or monitor pulse via the cord.
  - Suctioning of nose and mouth with bulb aspirate recommended if obvious obstruction from secretions.
  - Use slight downward pressure to deliver superior shoulder, then slight upward pressure to deliver lower shoulder.
  - Clamp cord after 1-3 minutes with 2 hemostats and cut between clamps.
  - Immediately wrap infant and give to mother – assistant to aid in monitoring child.
  - Deliver placenta – should feel lengthening / giving way of cord and gush of blood – keep placenta for pathology evaluation. (This process may take up to 30min. Never pull on the umbilical cord in attempts to speed delivery.)
  - “Externally” massage uterus to encourage contraction and limit bleeding.
  - If neonate appears to be stuck in the birth canal (i.e., turtling of the head), flex the mother’s hips (both knees to chest) in order to widen the birth canal.
  - Provide the neonate with safe and adequate hearing protection and hypothermia prevention as possible.

NEWBORN CARE & DISTRESS

Continued from:
- **TACTICAL EVACUATION Guideline,**
- **CHILDBIRTH Guideline, or**
- **Pediatric RESPIRATORY DISTRESS Guideline**

Maintain:
Universal Patient Care Guideline
(Mother and Newborn)

- **Airway Open?** (Breathing or Crying)
- **Good Tone?**
- **Full Term Delivery?**

YES → **Post Resuscitation Care**
- Clear Airway (bulb syringe mouth / nose)
- Dry Infant
- Keep Warm (wrap in blanket)
  - Avoid Hyper / Hypothermia
- Determine APGAR Score
- Treat Hypoglycemia (Glucose <40)
- Continuous Monitoring (with SpO_2)

NO

- Clear Airway (Bulb syringe Mouth / Nose)
- Dry Infant
- Stimulate (Foot Tap, Back Rub)
- Keep Warm (wrap in dry blanket)
- SpO_2 Monitor (if not already placed)
- Determine APGAR Score

- **HR <100?**
- **Apnea or Gasping?**
- **Labored Breathing?**
- **Persistent Cyanosis?**

NO → **Post Resuscitation Care**

YES

- Clear Airway
- **BVM (PPV): Titrate to 94-99% SpO2 at 30-60 breaths/min**
- SpO_2 Monitoring

HR <100? — **NO** → **Post Resuscitation Care**

YES

Take Ventilation Corrective Steps
(Intubate if NO Chest Rise)

HR <60? — **NO**

YES

- **Chest Compressions with PPV**
  (120 events/min: 90 compressions interspersed with 30 ventilations)
- **Consider Intubation**

HR <60? — **NO**

YES → **Epinephrine 1:10,000**
0.01-0.03mg/kg push q3-5min
(0.1-0.3mL of 1:10,000
10cc Cardiac Epi vial)

Consider:
1. **Hypoglycemia** (Treat Glucose <40)
2. **Shock**
3. **Pneumothorax** (Intubate)

1. **D12.5 1.0mL/kg IV** (Dilute D50 to ¼ strength (1mL D50 in 3mL NS)
2. **IVF or Blood 10mL/kg IV**
3. **Intubation**

Meconium Staining of Amniotic Fluid?
- Suction Mouth then Nose until clear with bulb syringe. Deep suction is no longer advised.

Targeted Preductal SpO_2 After Birth

1 min: 60-65%
2 min: 65-70%
3 min: 70-75%
4 min: 75-80%
5 min: 80-85%
10 min: 85-95%

Do NOT titrate O_2 for SpO_2 >95%

Signs of:
Dehydration
- Tachycardia, ↓BP
- Sunken Fontanelles
- No tears
- Dry mouth, tongue, skin
- ↓UOP

Fluid Overload
- Shortness of Breath
- Ankle / Sacral Edema
- ↑Jugular venous pressure
- Crackles in Lungs

APGAR SCORE
- Determine by end of 1st 60 seconds of care and repeat every 5 min.
- Score of 6 or less? Start Immediate Resuscitation.

(CPR: **90 compressions per 30 ventilations / min** – provide supplemental O_2 to titrate to 94-99%SpO2)

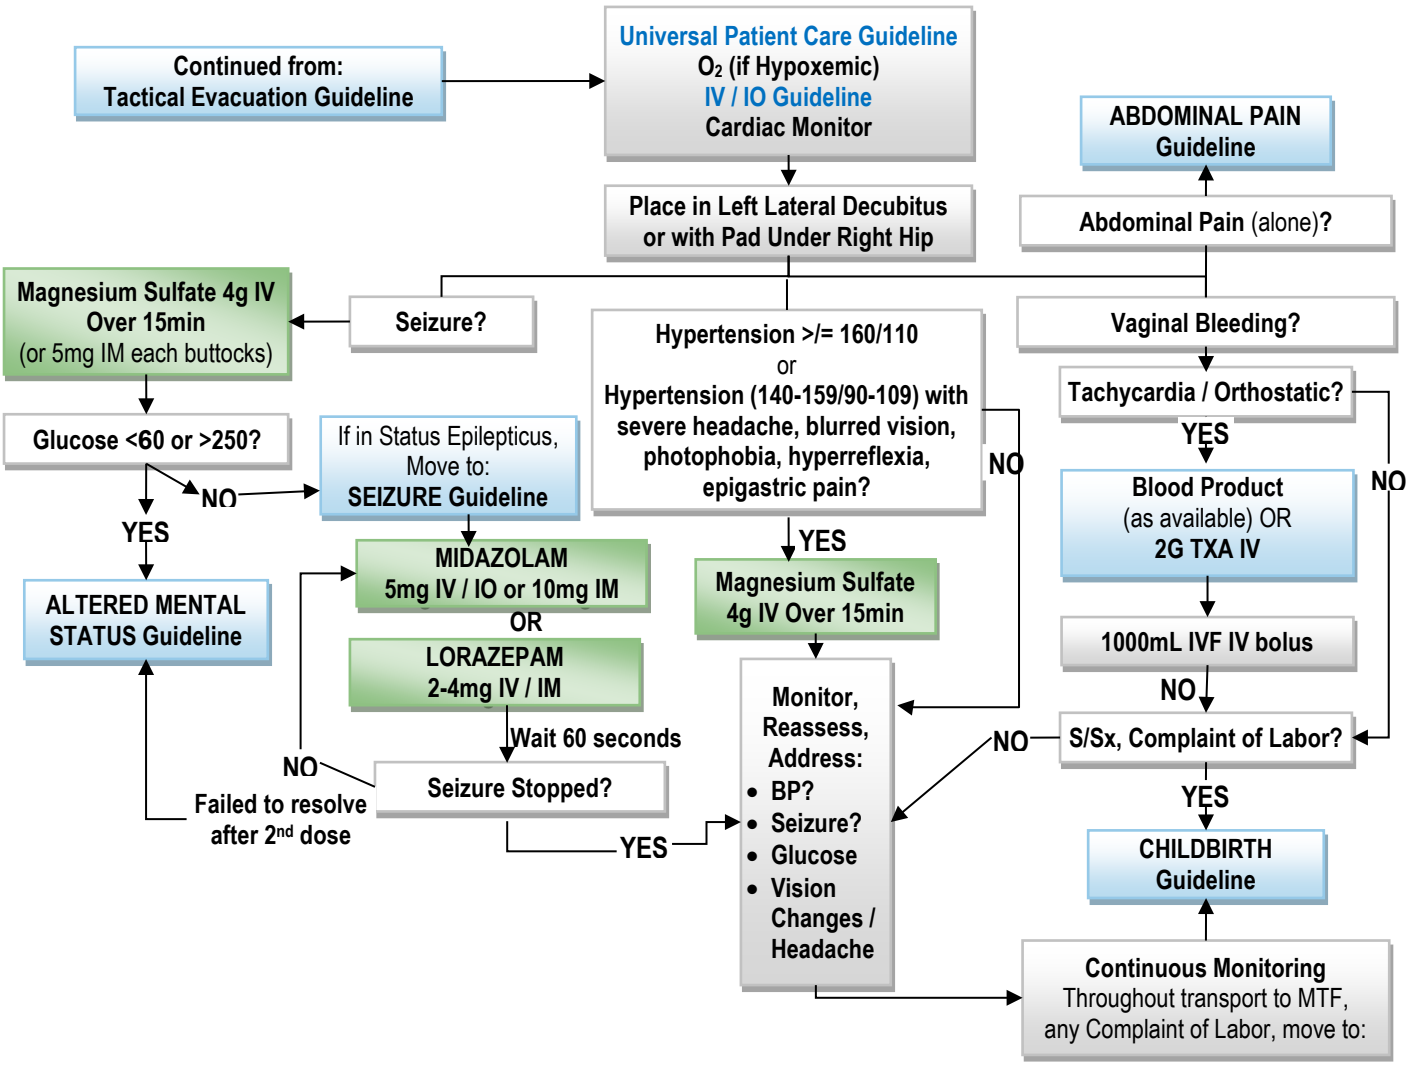
APGAR SCORING	0 POINTS	1 POINT	2POINTS	SCORE
Activity (Muscle Tone)	Absent	Arms and Legs Flex	Active Movement	
Pulse	Absent	Below 100 bpm	Over 100 bpm	
Grimace (Reflex irritability)	Flaccid	Some Extremity Flexion	Active motion (pull away, cough)	
Appearance (Skin color)	Blue, Pale	Body Pink, Extremities blue	Completely Pink	
Respirations	Absent	Slow, irregular	Vigorous cry	
			TOTAL APGAR:	

Severely Depressed	**0-3**
Moderately Depressed	**4-6**
Excellent Condition	**7-10**

OBSTETRIC EMERGENCY

Signs and Symptoms:
- Vaginal Bleeding
- Abdominal Pain
- Seizure
- Hypertension
- Headache
- Visual Disturbance

Differential Diagnosis:
- Pre-Eclampsia / Eclampsia
- Placenta Previa
- Abruptio Placentae
- Spontaneous Abortion



Pearls:
- Seizure / headache / vision complaints: can give Midazolam 0.1mg/kg IV every 15-30 or 1mg IV every2-3min up to 5mg while waiting for magnesium to take effect.
- Seizure activity in an OB patient signifies eclampsia.
- The best life support for the fetus is to resuscitate the mother.
- All pregnant / suspected pregnant patients should be kept in the left lateral decubitus position or have padding placed below the right hip to keep pressure off of the inferior vena cava.
- Use caution when using magnesium – it can lead to cardiorespiratory collapse with hypotension and decreased respiratory drive.
- Treat all hypertensive patients as if they are pre-eclamptic despite any prior history of hypertension.
- The leading cause of Postpartum Hemorrhage is Uterine Atony (lack of contracting), which can be treated with uterine massage

TREATMENT OF MINORS

INDICATIONS:

Responding to treat a minor patient without a parent or legal guardian representative available. For the purpose of these guidelines, all patients under age 18 years will be considered minors. Medical aircrew and medical directors should consult unit rules of engagement and applicable laws and adjust accordingly.

PATIENT MANAGEMENT PROCEDURE:

1. Treatment and transport of any minor requiring immediate care to save a life or prevent severe injury will be performed following the principle of implied consent for emergency care. (Assume any minor who needs treatment to save life, limb, eyesight, or to prevent severe injury has provided consent to treatment.)

2. **ALWAYS** act in the patient's best interest. **ALWAYS** maintain complete and careful documentation.

3. If the parent or guardian is present, follow these guidelines:
    a. Allow one (1) parent to accompany the child during transport after approval of the pilot in command (PC) **and** if it does not interfere with patient care or flight safety.
    b. In event of major trauma and/or cardiac arrest, judgment should be exercised in allowing parents to accompany the child. Recent evidence supports this practice in emergency departments and some EMS settings, but care should be exercised to maintain crew safety and mission accomplishment.
    c. Allow the parent to hold or touch the child, if possible, while assuring optimal transport restraints to assure safety.
    d. Remember to be open and honest to both parent and child about the child's condition and any treatment given. **DO NOT** diagnose, **DO NOT** deceive, and **DO** try to comfort the child and parent.

4. In many jurisdictions, parent or legal guardians **CANNOT** refuse consent for treatment/transport of a minor with a life-threatening condition. Contact your medical director in the event of the parent/guardian refusing treatment/transport of a minor with a life-threatening condition.

SEXUAL ASSAULT

INDICATIONS:

1. Reported and/or suspected assault on any person regardless of age or gender.
2. Trauma and/or bleeding to the vagina, rectum or buttocks that cannot be identified as being the result of any other cause.

REMARKS:

1. Focus shall be placed on the victim and on doing what is necessary and appropriate to support victim recovery and also, if a Service Member, to support that Service Member to be fully mission capable and engaged.
2. Medical personnel should be gender-responsive, culturally competent, and recovery-oriented.
   a. Medical providers giving care to sexual assault victims shall recognize the high prevalence of pre-existing trauma (prior to present sexual assault incident) and the concept of trauma-informed care.
   b. If the attending flight medic is not appropriately trained to utilize a Sexual Assault Forensic Evidence (SAFE) Kit, information will be forwarded to the Medical Treatment Facility in order to make the necessary arrangements to complete the SAFE Kit administration as soon as possible.
3. Flight Paramedics shall abide by the Sexual Assault Prevention and Response (SAPR) Program and coordinate with the Sexual Assault Response Coordinator (SARC) and Sexual Assault Prevention and Response Victim Advocate (SAPR VA). The SARCs shall serve as the single point of contact for coordinating care to ensure that sexual assault victims receive appropriate and responsive care.
4. Sexual assault victims shall be given priority and treated as emergency cases. Emergency care shall consist of emergency medical care and the offer of a SAFE Kit.

PATIENT MANAGEMENT PROCEDURE:

1. In the management of sexual assault patients, the DoD's first priority for victims is to protect, treat with dignity and respect, and to provide the medical treatment, care, and counseling that patients deserve. Under the DoD Confidentiality Policy, sexual assault victims have two reporting options: Restricted and Unrestricted. It is mandatory that all DoD health care providers (including 68Ws) adhere to the parameters of confidentiality and notification pursuant to each form of reporting.

   a. **Restricted Reporting**: Reporting option that allows assault victims to confidentially disclose the assault to specified individuals (e.g., SARC, SAPR VA, healthcare personnel) and receives medical treatment (including emergency care), counseling, and assignment of a SARC and SAPR VA; without triggering an investigation. The victim's report provided to healthcare personnel (including the information acquired from a SAFE Kit), SARCs, or SAPR VAs will NOT be reported to law enforcement or to the command to initiate the official investigative process unless the victim consents or an established EXCEPTION applies. Restricted reporting applies to Service Members and their military dependents 18 years of age and older. Additional persons who may be entitled to Restricted Reporting are NG and Reserve Component members. Only a SARC, SAPR VA, or healthcare personnel may receive a Restricted Report.

   b. **Unrestricted Reporting:** A process that an individual covered by this policy uses to disclose, without requesting confidentiality or Restricted Reporting, that he or she is the victim of a

sexual assault. Under these circumstances, the victim's report provided to healthcare personnel, the SARC, a SAPR VA, command authorities, or other persons is reported to law enforcement and may be used to initiate the official investigative process.

5. Priority treatment as emergency cases includes activities relating to access to healthcare, coding, and medical transfer of evacuation and complete physical assessment, examination, and treatment of injuries including immediate emergency interventions.
6. **DO NOT** attempt to examine the patient without informed consent except to treat immediate life, limb, or eyesight threats. SARC notification must not delay emergency medical care treatment of a victim.
    a. Limit cleaning of wounds to only determine severity.
    b. Check for associated or additional injury and/or other illness. Refer to appropriate medical treatment guidelines as appropriate.
7. In situations where installations do not have SAFE kit capability, the installation commander will require that the eligible victim, who wishes to have a SAFE, be transported to a MTF or local off-base, non-military facility that has a SAFE capability. A local sexual assault nurse examiner or other healthcare providers who are trained and credentialed to perform a SAFE may also be contacted to report to the MTF to conduct the examination.
8. Preserve all evidence:
    a. Bag all personal items (e.g., blood stained items, clothes). Paper bags are recommended if available, in order to prevent excess moisture accumulation and subsequent evidence degradation.
    b. Ensure all items are signed for before handing off.
    c. Ensure all interactions, statements made by the patient, and all treatment given is medically documented in patient care record while maintaining patient confidentiality.

PATIENT REFUSAL

INDICATIONS:

If a patient (or person[s] responsible for a minor) refuses treatment or transport, after pre-hospital providers have arrived on the scene, the following procedures should be carried out:

PATIENT MANAGEMENT PROCEDURE:

1. A Primary Assessment (to include vital signs) should be completed, if possible. Pay particular attention to the patient's mental status.

2. Any injuries or illnesses found to immediately threaten life, limb, or eyesight (or can be assumed will deteriorate enroute) should be addressed and treated immediately while enroute, to the greatest extent possible while assuring safety. With Patients that prevent treatment of these injuries, all should be done to encourage the patient seek treatment and any doubt of capacity should prompt treatment/transport under implied consent. Patient with decision-making capacity refusing treatment of life-threatening injury or illness require further clinical judgement and consultation with medical director prior to informed refusal.

3. Injuries or illnesses that do not represent imminent threats to life, limb, or eyesight (or considered unlikely to deteriorate enroute) may be addressed in accordance with the following:

   a. Determine the patient's (or parent's) decision-making capacity to make sound/ valid judgments concerning the patient's condition. If there are any doubts from the provider's aspect, consider treating in accordance with the **ALTERED MENTAL STATUS GUIDELINE** or **COMBATIVE PATIENT GUIDELINE.** Decision-making capacity means that:
      - The patient is awake, alert, and oriented to person, place, time and event.

        AND
      - The patient is able to understand his/her medical problem(s), and recite back an understanding of the medical problem(s) and risks of possible resulting problems or worsening of his/her medical condition if patient is not evaluated and treated.
   b. Ensure that you clearly and repeatedly explain to the patient or responsible parties of the concerns and possible risks involved in refusing medical care.
   c. Clearly document all findings during the patient assessment and any discussions with the patient regarding his/her condition as well as all persons involved with the patient. Document all statements made pertaining to the risks associated with refusing treatment and transportation and obtain a signature from a witness (crewmember) and the patient or parties responsible for the patient as to refusal of care.
   d. Clearly explain to **Military Personnel** why the treatment is needed**. Notify them that refusal of treatment may bring judicial or administrative adverse action upon them under UCMJ.**

SAMPLE PATIENT REFUSAL

DATE:_____

PATIENT REFUSAL FORM

PATIENT INFORMATION:

_____ _____ _____

COMBATIVE PATIENT

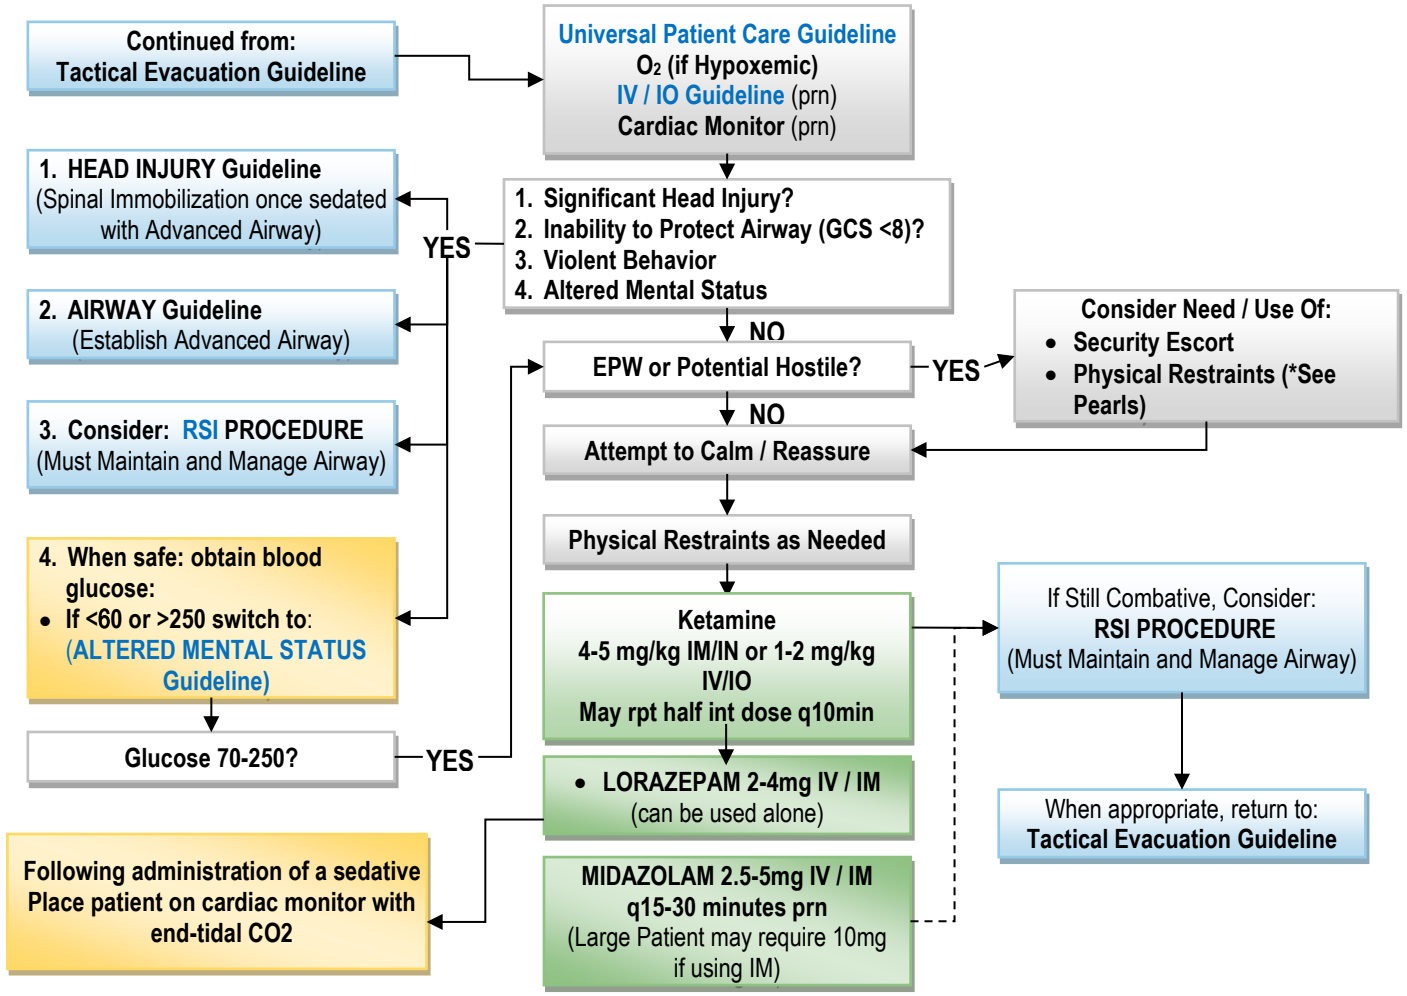
Signs and Symptoms:

- Bizarre Behavior
- Violent Activities
- Head Injuries / AMS
- Anxiety
- Tachycardia / Elevated BP

Differential Diagnosis:

- Head Trauma / Psychiatric Disorders
- Thyroid Dysfunction
- Hyper/Hypoglycemia
- Diabetic Ketoacidosis / Toxic Ingestion
- Environment (Hyper / Hypothermia)
- Hypoxia

Safety of Helicopter/Crew/other patients is first priority



Continued from:
Tactical Evacuation Guideline
Universal Patient Care Guideline
O2 (if Hypoxemic)
IV / IO Guideline (prn)
Cardiac Monitor (prn)
1. HEAD INJURY Guideline
(Spinal Immobilization once sedated with Advanced Airway)
2. AIRWAY Guideline
(Establish Advanced Airway)
3. Consider: RSI PROCEDURE
(Must Maintain and Manage Airway)
4. When safe: obtain blood glucose:
• If <60 or >250 switch to:
(ALTERED MENTAL STATUS Guideline)
Glucose 70-250?
YES
1. Significant Head Injury?
2. Inability to Protect Airway (GCS <8)?
3. Violent Behavior
4. Altered Mental Status
YES
NO
EPW or Potential Hostile?
YES
NO
Consider Need / Use Of:
• Security Escort
• Physical Restraints (*See Pearls)
Attempt to Calm / Reassure
Physical Restraints as Needed
Ketamine
4-5 mg/kg IM/IN or 1-2 mg/kg IV/IO
May rpt half int dose q10min
• LORAZEPAM 2-4mg IV / IM
(can be used alone)
MIDAZOLAM 2.5-5mg IV / IM
q15-30 minutes prn
(Large Patient may require 10mg if using IM)
If Still Combative, Consider:
RSI PROCEDURE
(Must Maintain and Manage Airway)
When appropriate, return to:
Tactical Evacuation Guideline
Following administration of a sedative
Place patient on cardiac monitor with end-tidal CO2

Pearls:

- ***Physical restraints** such as tying down patient hands to prevent pulling lines, etc., should be limited to the least amount necessary to accomplish treatments / prevent injuries. **(Kerlex gauze can be a useful restraint)**
  - **Do not jeopardize the patient's airway!** – Avoid hog tying, lying prone in restraints, sandwiching between spine boards, etc.
  - **Check Vitals, SpO_2, Pulse and Cap Refill every 5 minutes.**
- Combative patients present a very real threat to the safety of themselves, the medic, and the aircrew during flight. For this reason, any patient with altered mental status and the potential for combativeness that would threaten aircrew safety or themselves should be prophylactically sedated / paralyzed and intubated for the flight.
- Use of sedative medications adds risk of decreasing respiratory drive and should be used with caution. However, meds should be titrated to adequate dosage to control patient. Be prepared for airway interventions/vomiting if used. Cardiac arrest in patients with excited delirium/extreme agitation following restraint is well documented. Capnography in addition to cardiac monitoring is essential.

MWD Normal Clinical Parameters

for further reference see

Clinical Practice Guidelines for Military Working Dogs, 12 Dec 2018

Vital Signs

- **Temperature (rectal)- 99.5° to 103° F**
- **Heart Rate/ Pulse- 60 to 80 (at rest) bpm**
- **Respiratory Rate- 16 to 32 bpm**
  (Controlled panting is normal**)**
- **Blood Pressure- Systolic 120 mmHg, Diastolic 80 mmHg, Mean 90 to 100 mmHg**

Clinical Pearls for MWDs-

- Average MWD weighs 30-35 kg (German shepherd dogs, Belgian Malinois, Labrador retrievers).
  All drug dosages should be calculated based on measured or estimated body weight.
  DOG HANDLER CARRIES DRUG CARD FOR THE DOG
- IV catheterization access points are:
  - Cephalic vein on the cranial (superior) aspect of the forearm (figures 1 & 2)
  - Lateral saphenous vein on the lateral aspect of the hind limb at the distal tibial area (figure 3)
  - External jugular vein in the jugular furrow of the neck. Standard human central venous catheter kits can be used; the Seldinger technique is most reliable.
- IO catheterization access points are:
  - Greater trochanter of the humerus (figure 4 & 5)
  - Medial tibia just distal to tuberosity (figure 6 & 7)
- Arterial Pulse is palpated at the femoral artery on the medial aspect of the proximal thigh in the inguinal area (figure 8) or at the dorsal metatarsal artery on the dorsal aspect of the proximal hind paw.
- Heart sounds are best auscultated over the lower left lateral thoracic wall between the 4th and 5th intercostal space. (figure 9)
- 3-lead electrocardiograms are sufficient for MWDs. Adhesive electrodes should be taped to the pads of the paws of the left forelimb (**black** lead), right forelimb (white lead), and left hind limb (**red** lead). (figure 10)
- Pulse oximetry probes can be utilized on conscious dogs using the ear pinna, lip fold, or flank skin; while not optimal for oximetry, these alternative sites are generally acceptable. For optimal reliability place probe on tongue (only in unconscious dogs)

Figure 1- Vein best punctured toward the elbow.

Figure 2- Vein occlusion superior to elbow joint while elbow is in extension.

Figure 3- lateral saphenous vein on the hind limb of a MWD

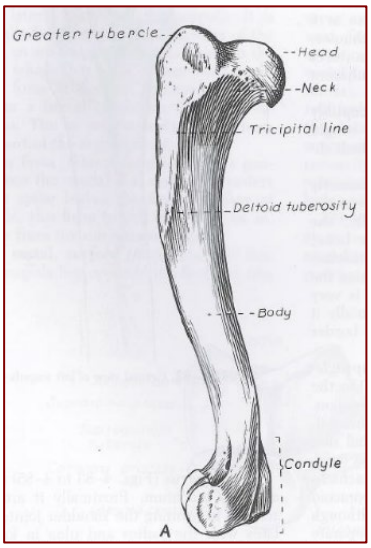


Figure 4 - Musculoskeletal view of greater trochanter of the humerus for IO catheter

Figure 5 - Shoulder IO catheter location

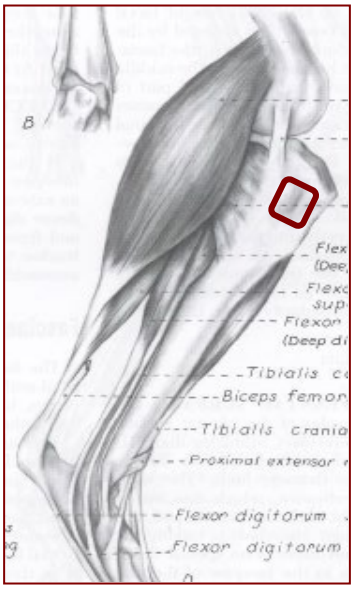

Figure 6 - Musculoskeletal view of medial tibia location for IO catheter just distal to tuberosity

Figure 7 - medial tibia IO catheter location just distal to tuberosity

Figure 8 - location for palpation of the femoral arterial pulse

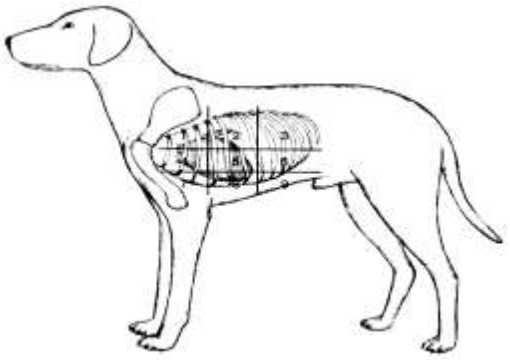

Figure 9 - optimal location for auscultation of the heart sounds and palpation of the heart beat

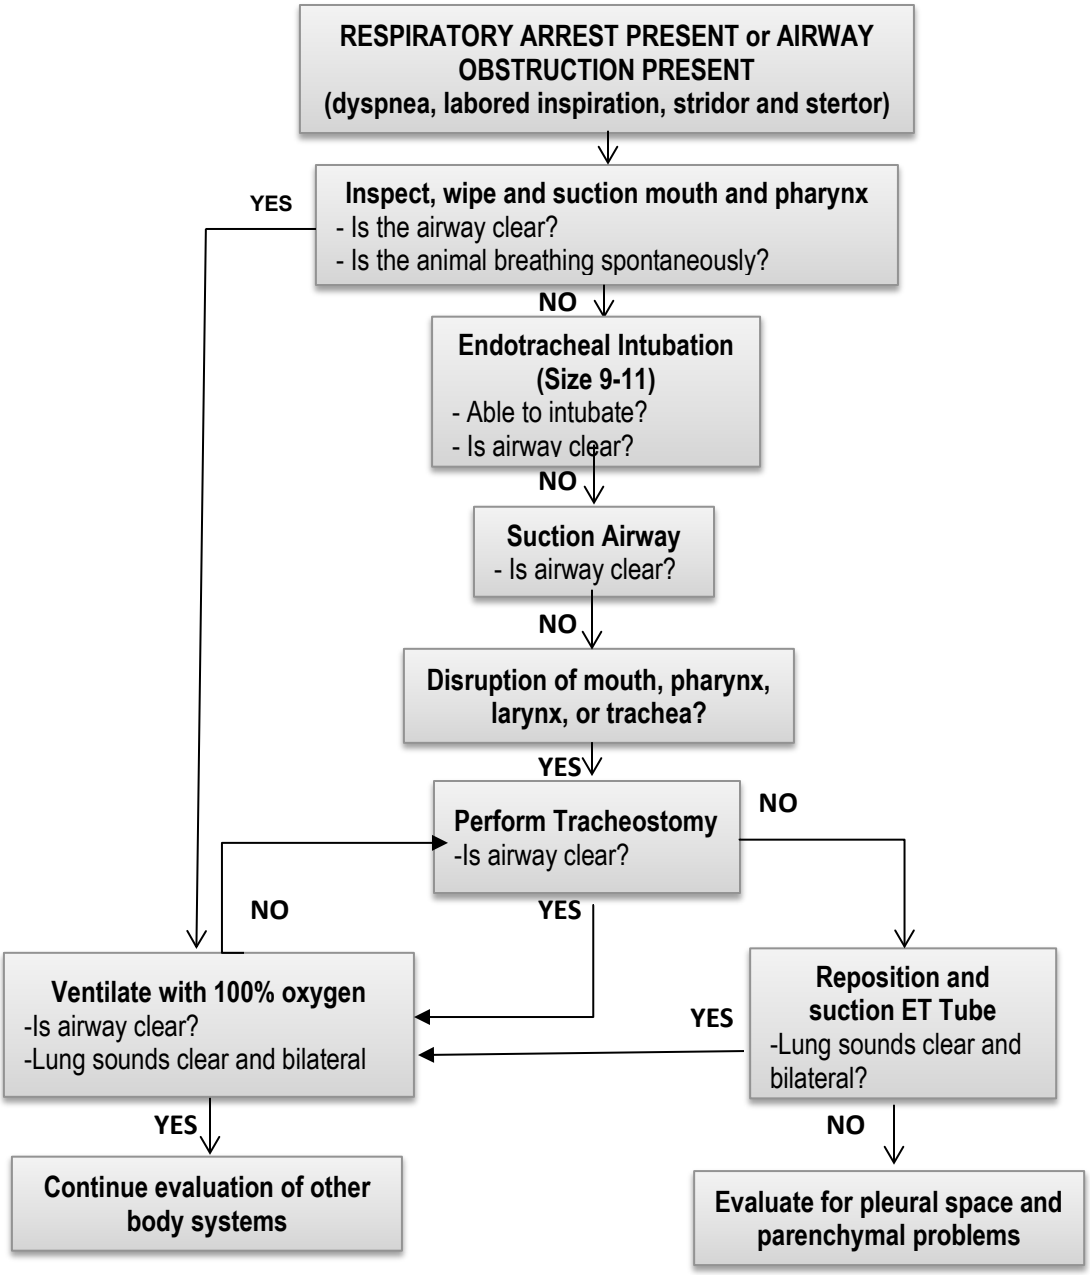
Figure 11- placement of pulse oximetry on tongue

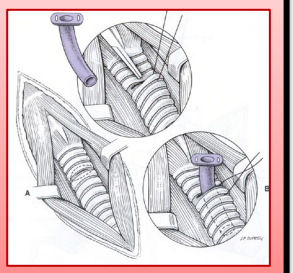
Figure 10 - placement of adhesive ECG electrode pads on the footpads

MWD Airway Management



100% Oxygen Supplementation Examples

Conscious or fractious muzzled dogs (10-15 L/min)



Orotracheal intubation or Tracheostomy (2 L/min)

Clinical Pearls:

- Unconscious MWDs: Use tracheal insufflation, orotracheal intubation, or tracheostomy. If there is an obstruction then bypass the obstruction until the patient is more stable. Do not use tracheal insufflation for >30 min.

- NOTE: intubation of the MWD is most easily performed with the dog in sternal or prone position, head and neck extended, and tongue pulled forward. Verify placement by palpating neck for 1 tube. If 2 tubes are felt, the tube is in the esophagus. Capnometer reading > 10mmHg also ensures correct placement.

MWD Heat Injury Treatment

MILD heat injury (heat stress) - excessive thirst, discomfort associated with physical activity, mild dehydration, but with controlled panting (i.e., the patient can control or reduce panting when exposed to a noxious inhalant such as alcohol).

↓

-Remove patient from source of heat, discontinue exercise, cool by fans or air condition, give cold water to drink.

↓

-Monitor patient for
- Body Temp every 15 mins
- Mentation / LOC
- Weakness / collapse
- Anxiety/ restlessness
- Shock

MODERATE heat injury (heat exhaustion) - heat stress present, as well as weakness, anxiety, and uncontrolled panting (i.e., the patient cannot reduce panting when exposed to a noxious inhalant), but central nervous system (CNS) abnormalities are not present.

↓

-Same as MILD but more aggressive cooling required Remove patient from all heat and stop all activity.

↓

-Cool by fans or air condition.
-Thoroughly soak the hair coat to the skin (room-temp) in order to reduce core body temperature < 105F.
-Give IV fluids 3-5 mL/kg/hr if not in shock

↓

-Monitor patient for
- Body Temp every 15 mins
- Mentation / LOC
- Petechiae / ecchymoses
- Weakness / collapse
- Anxiety/ restlessness
- Shock

SEVERE heat injury (heat stroke) – heat exhaustion are present, coupled with varying degrees of CNS abnormalities (changes in mentation and level of consciousness, seizures, abnormal pupil size, blindness, head tremors, and ataxia.

↓

-Triage-
- Establish airway
- Provide oxygen
- Establish IV for shock treatment

↓

-Aggressively cool patient until rectal temp is less than 105°F.
- Use only room temperature fluids.
- Give IV fluids (shock protocol)

↓

-Monitor patient for
- Vitals, Blood Glucose
- ECG arrhythmias
- Mentation / LOC
- Gait abnormalities
- Vision changes
- Seizure
- Rebound hypothermia

Clinical Pearls:

- **PANTING** is the only significant cooling mechanism for dogs.
- **NO** specific body temperature defines heat stroke in MWD's. Normal rectal temperature is 101° to 103° F in the MWD. Temperatures as high as 105.8°F have been associated with pathology. Most commonly, heat stroke is seen in MWDs with rectal temperatures greater than 107°F.
- **DO NOT** use of cold intravenous fluids, ice packs, or ice-water baths for cooling.
- Once the MWD's body temperature is =103°F **CEASE** all cooling efforts and monitor for rebound hypothermia, and prepare for rewarming measures. Actively warm the dog if the temperature <100°F
- Treat seizures with midazolam or diazepam 0.3 mg/kg IV, IO or Intranasal prn

MWD CPR Management

Cardiopulmonary Arrest Confirmed

BEGIN BASIC LIFE SUPPORT- SUSTAIN CPR for 2-3 minute cycles

- **Circulation-** Chest compressions, FAST and HARD, 100 compressions per minute
- **Airway-** Clear airway and intubate; perform tracheostomy if obstructed airway
- **Breathing-** Manually ventilate with 100% O_2 at 8-10 breaths per minute

BEGIN ADVANCED LIFE SUPPORT
ECG (determine arrest rhythm)
IV / IO access for drug delivery

VF or VT

- Defibrillate- **2-5 J/kg** biphasic
- Resume chest compressions x 1 cycle (2 min)
- Defibrillate twice more, with 1 compression cycle between each counter-shock, if refractory
- Drug therapy if counter-shock no successful:
  - Epinephrine **0.01 mg/kg** IV/IO
    or
    Vasopressin **0.8 U/kg** IV/IO **once**
    and
  - Lidocaine **2 mg/kg** IV/IO
    or
  - Amiodarone **5-10 mg/kg** IV/IO
- Repeat counter-shock (50% INCREASED initial energy) if refractory

ASYSTOLE/ BRADYCARDIA/ PEA

- Drug therapy:
  - Atropine **0.04 mg/kg** IV/IO *only if bradycardia preceded arrest*
  - Epinephrine **0.01 mg/kg** IV/IO
    and
    Vasopressin **0.8 U/kg IV/IO once**

Reprinted with permission from the Veterinary Emergency & Critical Care Society (veccs.org) RECOVER Initiative CPR Emergency Drugs and Doses chart.

Clinical Pearls:

- 70% of MWDs that arrest will have PEA, asystole, or sinus bradycardia as the initial arrest rhythm. Epinephrine or vasopressin are best choices for these rhythms or for empiric use if ECG capability is not available

- Avoid interrupting chest compressions! The key to successful resuscitation is to SUSTAIN chest compressions aggressively for 2-3 minutes before stopping to check status.

- Most people apply too little force when performing chest compressions! Do not be concerned with breaking ribs or injuring the heart or chest with BLS. In contrast to CPR in people, the thorax of MWDs is more compliant and fractures are rare

MWD Analgesia and Sedation

Sedation Protocols in the Military Working Dog

MWDs may become fractious during flight and chemical restraint by intramuscular injection will likely be required to facilitate IV catheter placement and treatment of a conscious MWD

MILD SEDATION

- **INDICATION**: Relax MWD for examination, handling, reducing anxiety
- **PROTOCOL:** Midazolam 0.3 mg/kg IM AND Hydromorphone 0.2 mg/kg IM
  - **Hydromorphone 0.2mg/kg IM may be substituted for morphine**
- **EXPECTATION:** MWD will be calm, but reactive and noise sensitive

DEEP SEDATION

- **INDICATION**: First line protocol for fractious MWD
- **PROTOCOL:** Midazolam 0.3 mg/kg AND Ketamine 5 mg/kg AND Hydromorphone 0.1 mg/kg IM
  - **Hydromorphone 0.1 mg/kg may be substituted for morphine IM**
- **EXPECTATION:** The MWD will not be able to walk but cannot be intubated. MWD may be aroused with significant stimulation and maintains laryngeal and palpebral reflexes

If MWD is suspected of having PAIN or PAIN is anticipated, please provide analgesia

Intermittent IV or IM supplementation

Or

Hydromorphone 0.1-0.2 mg/kg q 2-4 hours

Morphine Sulfate 0.2-0.5 mg/kg q 4-6 hours

- IV catheter (discretional)
- Give Midazolam 0.3 mg/kg IM & Hydromorphone 0.2 mg/kg IM q 2-4 hours

Continuous Infusion

Or Or

Fentanyl 2-10 mcg/kg/hour

Morphine 0.1-0.25 mg/kg/ hour

Hydromorphone 0.02-0.05 mg/kg/hour

- Place IV catheter once the MWD is controlled
- Give Midazolam 0.3 mg/kg IM & Ketamine 2 mg/kg IM & Hydromorphone 0.1 mg/kg IM
- Can also use Propofol in 1 mg/kg boluses IV as needed to allow catheterization or intubation

Clinical Pearls:

- Dosages for analgesics in dogs are significantly higher than for people.
- Assessment of pain in dogs is difficult. Health Care Providers should err on side of providing analgesia. Properly performed, it is safe and effective, and analgesia is critically important for safe handling and alleviation of pain.
- Note that all protocols have analgesia incorporated into them. Additional analgesia can be provided by the IV/IM or PO route, as necessary.
-Opioids cause emesis, usually within 5 minutes of administration. Be prepared to remove the muzzle to minimize aspiration risk. Hydromorphone causes excessive panting; use caution with head injuries, GDV, and respiratory disease.

- **CAUTION: Do NOT use acetaminophen or ibuprofen in MWDs, as these drugs can cause liver toxicity. AVOID use of NSAIDs such as naproxen and aspirin in emergently ill or injured MWDs.**
- **OPIOID REVERSAL:** At appropriate doses, dogs appear less susceptible to opioid-induced respiratory depression and excessive sedation. However, opioid side effects can be reversed in the dog using NALOXONE 0.01-0.02 mg/kg slow IV to effect if needed. **Note that this will reverse analgesia as well as sedation!**

MWD Gastric Dilation-Volvulus

GDV is a **rapidly life-threatening** condition common in MWDs. In GDV, the stomach rapidly dilates (gastric dilation) with fluid, food, and air, and then rotates along the long axis (volvulus) and causes shock by interfering with venous return from the abdomen and pelvic limbs.

Clinical Signs:
- varying degree of abdominal distention/tympany, non-productive retching, attempted vomiting without result; signs of pain (grunting when palpating stomach); signs of anxiety; inability to lay comfortably; and signs of compensatory shock (tachycardia, tachypnea)

Initiate Monitoring:
ECG, NIBP, SpO_2, $ETCO_2$, Evaluate for dysrhythmias, hypotension, hypoxemia, hypo- or hypercapnia

Treat Shock
- Give supplemental O_2
- Place at least 2 IV or IO catheters in the forelimbs (preferably one central)
- Give IV or IO crystalloid therapy utilizing the **10-20-10-10** fluid guideline
- Give **hydroxyethyl starch** (**HES**) boluses (10-20 mL/kg) IV or IO as needed to maintain normal blood pressure. Repeat this bolus if no response to therapy.
- Give **hypertonic saline (HTS)** IV bolus of 4 mL/kg over 5 minutes (if 7-7.5% HTS is available) for MWDs that fail to respond to two or three quarter-shock boluses of crystalloids and/or one or two boluses of HES.

Decompress the Tympanic Stomach
- Position self on left side, or lay dog on left side
- Locate Insertion point: Palpate last rib, move hand two inches caudal to the last rib, midway between the spine and the ventral border of the abdomen on the right side, auscultate the lateral abdominal wall at most distended area while percussing the wall with a finger. Loudest "ping" is the site of insertion.
- Clip hair over a 6-inch area over the area.
- Prepare area with a surgical scrub.
- Forcefully insert 14-18 gauge IV over-the-needle catheter through the skin, abdominal wall, and stomach wall.
- Note gas or air escaping through the needle from the stomach to signify a successful attempt. .
(**DO NOT ATTEMPT SECOND INSERTION** if first is unsuccessful)
- Apply gentle external pressure to abdominal wall to assist exiting air.
- Remove catheter once air is evacuated.

Provide analgesia utilizing analgesia guideline

Clinical Pearls:

Goal is to treat for shock, decompress stomach, and transport for surgical intervention.

Monitor for ventricular arrhythmias, persistent shock and recurrent dilation

Surgery is REQUIRED for definitive treatment to derotate the stomach.

MWD Shock Fluid Therapy

The "10-20-10-20 Rule"

Shock Fluid Therapy Protocol of MWDs

- Place multiple large-bore intravenous catheters, perform venous cut-down, and/or place intra-osseous (IO) catheters. Provide flow-by supplemental oxygen therapy.

- Give IV or IO crystalloid therapy utilizing the 10-20-10-10 fluid guideline:

1. Calculate total fluid "shock" volume (**90 mL/kg**) that might be required.
2. Collect baseline physiologic and clinical data (mentation, NIBP, HCT, TP, HR, pulse quality, CRT, mucous membrane color).
3. Give one quarter of the calculated "shock" volume over the first **10** minutes.
4. Reassess the patient's pulse quality, CRT, mucous membrane color, heart rate, NIBP, etc.
5. Give another one quarter of the calculated "shock" volume over the next **10**-**20** minutes, if necessary.
6. Reassess baseline data.
7. If HCT > 20% and TP not below 50% of starting value, and further fluid therapy is required, then give another one quarter of the calculated "shock" volume over **10** minutes.
8. Reassess baseline data.
9. If fluid therapy is still required, give the final one quarter of the calculated "shock" volume over **10**-**20** minutes.

- Give a hydroxyethyl starch (HES) IV or IO bolus of 10-20 mL/kg over 5-10 minutes if clinical signs of shock do not abate after the first 30 minutes (first 2 quarter-shock IV challenges) of crystalloid fluids, or response to crystalloid challenges is not sustained. Repeat this bolus if no response to therapy.

- Give a hypertonic saline (HTS) IV bolus of 4 mL/kg over 5 minutes (if 7-7.5% HTS is available) for MWDs that fail to respond to two or three quarter-shock boluses of crystalloids and/or one or two boluses of HES.

Clinical Pearls:

-Quick calculation for shock dose: Add a zero to the dog's weight in POUNDS for the quarter shock volume in mLs.

- CAUTION: Human blood products and albumin, or other animal blood products, must never be given to dogs, given the high risk of anaphylactic reactions.

- Blood product transfusions for MWDs are **ONLY** available from Veterinary Service Support units and their administration is only authorized under the direct supervision of a veterinarian.

-Clinical target for resuscitation end point is a mean arterial pressure (MAP) of > 65 mmHg or a systolic of > 90 mmHg. Neonatal or pediatric blood pressure cuffs must be used.

-Consider TXA 10 mg/kg in 100 mL NS or LRS, IV over 15 min but NOT LATER THAN 3 HOURS post injury

DRUG	STANDARD DOSING	SMALL ADULT (60KG)132LBS	ADULT (80KG)176LBS	LARGE ADULT (100KG)220LBS	INDICATIONS	RESTRICTIONS/ WARNINGS	DURATION	REPEATABILITY/ MAX DOSE

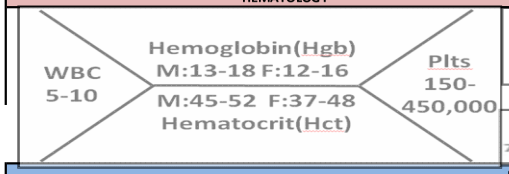
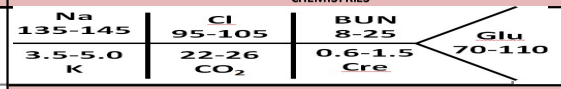
Ketamine ** HIGH DOSE	1-2 mg/kg IV/IO >2 min	**60-120mg**	**80-160mg**	**100-200mg**	Dissociative Sedation/ RSI	HTN, emergence, avoid sub- dissociative doses	10-20 min	1/2 to Full dose Q 10-20 PRN for sedation or 1-3 mg/kg/hr infusion
Propofol (Bolus)	1-2.5 mg/kg bolus IV/IO, q 5-10min PRN	**30-90mg**	**40-120mg**	**50-150mg**	RSI/General Anesthesia (Non-analgesic)	Hypotension (up to 30% of MAP)	3-10 min	Titrate to effect
Propofol (Constant Infusion)	10-75 mcg/kg/min IV/IO	**600-4500 mcg/min**	**800-6000 mcg/min**	**1000-7500 mcg/min**	General Anesthesia Maint. (Non-analgesic)	Hypotension (up to 30% of MAP)	Infusion	Titrate to effect
Etomidate	0.3mg/kg IV/IO push	**18mg**	**24mg**	**30mg**	Sedation, RSI (Non-analgesic)	Repeat doses can cause adrenal suppresion	5-10 min	NO REPEAT
Midazolam (Versed)**	0.05-0.1mg/kg IV/IO >1 min	**3-6mg**	**4-8mg**	**5-10mg**	Sedation, Seizures	BP/Resp drop	10-30 min	PRN q 15-30min if BP/Resp stable
PARALYTICS								
Rocuronium (Zemuron)	0.6-1.2 mg/kg IV/IO push	**60mg**	**80mg**	**100mg**	RSI/ Maint of paralysis	Must maintain PT airway	30-60min	PRN q 30-45min for paralysis
Succinylcholine	1-1.5 mg/kg IV/IO push	**75mg**	**100mg**	**125mg**	RSI	RSI Only	5-9 min	NO REPEAT
Vecuronium	0.1 mg/kg IV/IO push Reconstitute w/ 10 ml NS	**6mg**	**8mg**	**10mg**	Maint of paralysis	Must maintain PT airway	40-90 min	PRN q 40-90 min for paralysis
PRESSERS								
Epinephrine1mg/10mL	1mg/500ml NS= 2mcg/ml	**2-20mcg IVP q 2-5min or 2-20mcg/min IV/IO infusion**			Hypotension	Must be diluted/ Max resuscitation w/blood 1st	Infusion	Start low; Titrate to desired response
Norepinephrine (Levophed)	4mg/500 ml= 8 mcg/ml	**Start 2-20mcg/min infusion initally. (adjust for BP) Once BP is appropriate, 2-4mcg/min**			Hypotension	Max resus w/ blood 1st	Consistent Infusion	Start at lowest dose. Titrate up by 0.5mcg/min to MAP >60
Phenylephrine(NEO)	10mg/100ml NS= 100mcg/ml or 10mg/250ml NS= 40mcg/ml	**50-200mcg (1-5 ml) q 5-10 min IVP/IO**			Hypotension	Must be diluted/ Max resus w/ blood 1st	5-10 min	PRN to maintain SYS BP; start w/ low doses and titrate PRN
OD/Tox Ingestions (See also Sodium Bicarbonate, Calcium Chloride)								
Glucagon Kit	3-10mg IV/IO/IM	**3-10mg bolus; follow w/ 3-5mg/hr infusion**			Beta/Ca-ch blocker OD	Dosage is higher than kits	UNK	Titrate infusion for hemodynamics
Naloxone (Narcan)	0.4-2mg IV/IO/IM	**0.4-2mg titrated to appropriate ventilation**			Opioid OD	Use minimum needed	20-60 min	Q 2-3 min PRN (Max 10mg)
ANTI-EMETICS								
Zofran(Ondansetron)	4-8mg IV/IO/IM/PO	**4-8mg >30 sec**			Antiemetic	Can cause QT prolongation	4-6hrs	Max 8mg q 6 hrs
Promethazine (Phenergan)	12.5-25mg IV/IO/IM	**12.5-25mg**			Antiemetic/Sedation	Altered LOC/ Vesicant	4-6hrs	Max 25mg q 4 hrs
ANAPHYLAXIS								
Epinephrine 1mg/1mL	0.3-0.5mg IM; 0.1mg IV/IO	**1 Auto-Injector or 0.3mg IM; 0.1mg IV/IO**			Anaphylaxis	Hold for 10 sec	5-15m	Add doses Q 5-15 min until improve
Diphenhydramine (Benadryl)	25-50mg	**25-50mg PO; 50mg IV/IO**			Antihistamine	Minor sedation	4-8hrs	Max 50mg
Methylprednisolone/Solu-Medrol	125mg IV/IO	**125mg**			Anaphylaxis/Asthma	Do not use for head Tx	4hrs	NO REPEAT
RESPIRATORY (See also: Methylprednisolone)								
Albuterol(Nebulizer)	2.5-5mg	**2.5-5mg q 20 min prn (mixed in 3ml NS)**			Bronchodilator	Cardiac arrhythmia	1-4hrs	Max 3 initial doses; q 1-4hrs PRN
Albuterol(MDI)	4-8 Puffs	**4-8 Puffs Q 1-4 hrs**			Bronchodilator	Cardiac arrhythmia	1-4hrs	PRN q 1-4 hours
Epinephrine 1mg/1mL	0.3-0.5mg SQ/IM ***or*** 0.5ml Neb	**0.3-0.5mg SQ/IM q20min PRN *or* 0.5ml w/ 3ml NS**			Bronchodilator	No IV use	5-15m	Neb over 15 min/ Max 3x for SQ/IM
HYPOGLYCEMIA								
D50	10-25 Grams IV/IO	**20-50ml >5min**			Hypoglycemia	Intracranial hemorrhage	UNK	Titrate; avoid over-correction
Glucagon Kit	1mg	**1 Kit (1mg) IV/IM**			Hypoglycemia	Only if D50 not available	UNK	REPEAT every 20min
CARDIAC (See also Morphine or Fentanyl for AMI pain)								
Aspirin, Chewable, 81mg	324mg PO	**4 X 81mg Tablets (Chewed)**			Angina/ AMI	Must be chewed	4-6hrs	NO REPEAT
Nitroglycerin Tablet/Spray	0.4mg SL	**1 Tab/Spray SL Q 3-5 min---MAX 3**			Angina/ AMI	Maintain SYS BP>90	20-30 min	May repeat up to max of 3 Doses
Epinephrine 1mg/10mL	1mg	**1mg (1 amp) IV/IO Q 3-5 min for Arrest**			Pulseless Arrest	Profusing Tachycardia's	3-5 min	Repeat Q 3-5min w/ CPR-No Max
Amiodarone (Cardiac Arrest)	300mg 1st Dose/ 150 mg 2nd Dose (Follow w/20ml NS flush)	**300mg IV/IO bolus. If no change in 3-5min give 150 mg IV/IO.**			Refractory Pulseless V-Fib/V-Tach	Sinus Bradycardia, 2nd/3rd Deg Block	3-5 min	Max 2 doses
Amiodarone (Infusion)	150mg over 10-15min, followed by 1mg/min for 6hrs	**150mg infusion over 10-15min; followed by 360mg (1mg/min) infusion over 6hrs**			Hemodynamically unstable V-Tach/SVT	Sinus Bradycardia, 2nd/3rd Deg Block	Maintain drip	May repeat 150mg infusion q 10 PRN. Do not exceed 15mg/min
Adenosine	6mg/ 12mg IV/IO Rapid Push	**6mg 1st dose/12mg 2nd dose----Fast push w/ rapid, large (>20cc) flush**			Stable, narrow complex tach/PSVT	May cause transient Asystole following push	1-2 min	Give 2nd dose if no rhythm change in 1- 2 min
Atropine	1mg IV/IO	**1mg q 3-5 min**			Symptomatic Bradycardia	Glaucoma	5-15min	MAX 3mg (3 doses)
Epinephrine 1mg/10mL	0.05-0.5mcg/kg/min	**2-10mcg/minute infusion titrated to desired effect**			Symptomatic Bradycardia	Use if refractive to Atropine/Pacing	5-15min	MAX 3mg (6 doses)
Magnesium Sulfate	1-2 Gram IV/IO	**1-2 Gram diluted in 50ml D5W over 15 min(Torsades w/ pulse/VF/V-Tach)**			Torsades De Pointes (with or without pulse)	AV Blocks	30 min	Infusion of 1-2 Grams per hr needed following loading dose

DRUG	STANDARD DOSING	SMALL ADULT (60KG)132LBS	ADULT (80KG)176LBS	LARGE ADULT (100KG)220LBS	INDICATIONS	RESTRICTIONS/ WARNINGS	DURATION	MAX DOSE/ REPEATABILITY
CARDIAC-continued								
Sodium Bicarbonate	1mEq/kg IV/IO	**60mEq**	**80mEq**	**100mEq**	TCA OD; Prolonged Cardiac Arrest	Do not mix with other meds/ Flush line after	1-2hrs	Maint Infusion of 100-150mEq in 1L D5W @ 100-200ml/hr for TCA OD
Labetalol	10-20mg IV/IO over 1-2min	**10-20mg IV/IO over 1-2min**			HTN Urgency/Emergency	Lower MAP by <20%	15-60 min	Repeate one time
Calcium Chloride (100mg/ml)	Ca Gluconate can alternatively be used @ 3x doses listed here (except for Beta Blocker OD)	**500-1000mg over 2-5 min for Hyper K issues; 20mg/kg >5-10min for Beta Blocker OD; 1Gram >5min for Ca Ch Blocker OD; 1G>5min after Blood**			Hyperkalemia/ Beta&Calcium Channel Blocker OD	Central Line use preferred	30min-4 hrs	20mcg/kg/hr infusion for Beta OD; 1000mg Q 10-20 x 3 doses PRN for Ca Chan Blocker OD
CBRNE								
Atropine	0.05-0.1mg/kg IV/IO q 5-10 min PRN	**3mg**	**4mg**	**5mg**	Organophosphate/ Nerve Agent	Requires large amounts of Atropine (5-20 boxes)	5-15min	Double dose if previous dose does not relieve secretions(atropinization)
Pralidoxime Chloride (2-Pam) (DuoDote ATNAA)	1-3 Auto-Injectors (600mg ea)	**Inject 1-3 injectors (based on sverity of symptoms) IM. DuoDote/ATNAA Injector contains both Atropine (2.1mg) and 2-Pam(600mg)**			Organophosphate/ Nerve Agent	Use Atropine 1st if only using single dose 2-Pam (Mark 1/NAAK Kit)	15min	If symptoms remain after 15 min, re- inject subsequent doses (Max 1800mg 2 Pam)
Multi-Use/ Seizures/ Other								
Diazepam	Anxiety: 2-10mg IV/IM q 6hrs///Seizures: 5-10mg q 3-4hrs///Seizures following Nerve agent Exposure: 10mg IM for seizures or if 3x Mark 1 Kits used				Anxiety/ Seizures/ Nerve Agent Seizures	Respiratory Depression	20-30min	Max dose 30mg for seizures
Lorazepam	1-2mg IV/IO	**Seizures = 1-2mg q 10-15 prn; Agitated/Combative Patient = 1-2mg q 30-60**			Seizures/ Agitated or Combative Patient	Respiratory Depression	30-120min	Max 8mg in 12hrs for seizures
Magnesium Sulfate	1-2 Gram IV/IO	**Seizures = 1-2G over 30 min; Wheezing/ Respiratory Distress (3rd line) = 2G over 20 min; (Pre)Eclampsia = 4-6G over 15-20min**			Seizures/ Wheezing in Resp Distress/ (Pre)Eclampsia	Dilute into 50-100ml NS or D5W	30 min	2 Grams/hr infusion needed following loading dose for Eclampsia
Mannitol (20%)	1 Gram/kg IV over <20 min	**60G**	**80G**	**100G**	Mod to severe head Tx	Avoid in HoTN Pt's	3-8hrs	Follow with 0.25 Gram/kg IVP q 4hrs
FLUIDS								
Resuscitation (Crystaloid)	≤20ml/kg	**250-500 ml Bolus to achieve systolic BP >90**			Hypo-tension/volemia	Blood is 1st fluid choice	PRN	Titrate to maintain SBP >90
Maintenance	1-2 ml/kg	**75ml/hr(TKO)**	**105ml/hr(TKO)**	**150ml/hr(TKO)**	IV access/Homeostasis	Do not over hydrate	PRN	Titrate to effect
Burns >20% TBSA	LR 10ml * %TBSA (Based on 40- 80kg adult)	**10ml * % BSA Per Hour**	**10ml * % BSA Per Hour**	**10ml * % BSA+200ML Per Hour**	>20% TBSA partial or full-thickness burns	Track start time and amount infused	N/A	Add 100ml/hr for each 10kg over 80kg
Hypertonic Saline (3%)	0.1-1 ml/kg/hr	**250ml bolus followed by 50-100ml/hr**			ICP Reduction	Use only in Head Injuries	N/A	MAX 250ml
HetaStarch/Hextend (HTS)	250-500 ml	**250-500ml to achieve sys BP >90**			Int/Ext Hemorrhage	Equates to 1.5 L NS	2+ weeks	PRN up to 1500ml/day
Blood Products and Management	**(See also Epinephrine and Benadryl for Hemolytic Reactions)**							
PRBC (1u=250ml)	10ml/kg	**1-2 units PRN to achieve Sys BP ~90 (Shelf Life =42 days)**			Int/Ext Hemorrhage/ Uni Donor	O- Neg Monitor for Anaphylaxis/ Hyperthermia/HyperK	PRN	Repeat PRN to maintain SYS BP >90/ MAP >60/hemostasis
FFP (1u=200-250ml)	10ml/kg	**1-2 units PRN to achieve 1:1 ratio w/ PRBC's (Shelf Life(thawed) =5 days)**			Int/Ext Hemorrhage/ Uni Donor	AB+ Monitor for Anaphylaxis/ Hyperthermia	PRN	Ideal ratio of FFP:PRBC:Platelets is 1:1:1
Acetaminophen	500mg PO or 1G IV	**500mg PO or 1Gram IV infusion**			Febrile Reaction	Infuse slowly	6hrs	Use only for Non-Hemolytic react

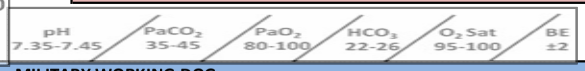
HEMATOLOGY



CHEMISTRIES



BLOOD GAS



VENTILATOR MANAGEMENT

Initial Vent Settings	
MODE	AC/ ASV (Hamilton T1 only)
RATE	14BPM
FiO2	1.0 (100%)
I:E	1:02
TIDAL VOLUME	6mL/kg (Ideal body weight)
PEEP	5 cm/H2O
Ideal Body Weight Calculation	
Men (kg)	50.0 + 2.3 x (Ht - 60 in)
Women (kg)	45.5 + 2.3 x (Ht - 60)

Troubleshooting

D.O.P.E.-- **D**isplacement; **O**bstructions; **P**neumothorax; **E**quipment Failure

MILITARY WORKING DOG

VITALS	Normal	Excited
Temperature	101-103 ºF	103 ºF
Respirations	16-30/MIN	Panting
Blood Pressure	120/80 (avg) mm Hg; MAP 90-100	
Heart Rate	60-80	
$EtCO_2$	35-45 mmHg	

FLUID MANAGEMENT

Shock: Calculate 90ml/kg for total fluid to be infused: Give 25% > 10 min; reasess; give 25% > 20 min(PRN); reassess; give 25% > 10 min(PRN); last 25% >10 min (PRN)

Intubate w/ 10.0 ET tube

Defib 2-5 Joules/Kg

INDICATION	K9 MEDICATIONS	NOTES
Anelgesia--Intermittent IV/IO/IM	**HYDROMORPHONE** 0.1-0.2mg/kg Q2-4hrs **OR MORPHINE** 0.2-0.5 mg/kg Q4-6hrs	
Analgesia-- Continuous IV/IO Infusion	**FENTANYL** 2-10 mcg/kg/hr **OR MORPHINE** 0.1-0.25 mg/kg/hr **OR HYDROMORPHONE** 0.02-0.05 mg/kg/hr	
Mild Sedation-- IM	**MIDAZOLAM** 0.3mg/kg IM **AND HYDROMORPHONE** 0.2mg/kg IM Q2-4hrs	
Agitated K9 Sedation-- IM 1st/IV PRN	**MIDAZOLAM** 0.3mg/kg **AND KETAMINE** 2mg/kg **AND HYDROMORPHONE** 0.2mg/kg	
Alternate K9 Sedation-- IV/IO	**PROPOFOL** 1 mg/kg boluses PRN to allow catheterization or intubation	
Cardiopulmonary Arrest BLS	Compressions @ 100/min; establish airway; Resperations @ 8-10/min for 2-3 minutes before ALS	
V-FIB/V-TACH	**Defib 2-5J/kg---2min CPR---Defib---EPI 0.01mg/kg AND Amiodarone 5-10mg/kg---2min CPR---Defib---2min CPR---Defib---EPI 0.01mg/kg AND Amiodarone 5-10mg/kg---2min CPR**	
ASYSTOLE/PEA/BRADYCARDIA	**ATROPINE** 0.04mg/kg IV/IO **AND EPINEPHRINE** 0.01 mg/kg	

ANTIBIOTIC THERAPY CHART

**Post-injury antimicrobial agents are recommended to prevent early post-traumatic infectious complications, including sepsis, secondary to common bacterial flora. Selection is based on narrowest spectrum and duration required to prevent early infections prior to adequate surgical wound management. This narrow spectrum is selected to avoid selection of resistant bacteria. The antimicrobials listed are not intended for use in established infections, where multidrug-resistant (MDR) or other nosocomial pathogens may be causing infection.*

Injury	Preferred Agent	Frequency	Duration
Extremity Wounds (Includes Skin, Soft Tissue, and Bone)			
Skin, soft tissue, **without** open fractures	Cefazolin 1-2g Or Ertapenem 1g	q 6-8hrs x 1 dose	24 hours
Skin, soft tissue, **with** open fractures, exposed bone, or open joints	Cefazolin 1-2g Or Ertapenem 1g	q 6-8hrs x 1 dose	24 hours, then with each subsequent I&D until soft tissue coverage
Thoracic Wounds			
Penetrating chest injury	Cefazolin 1-2g Or Ertapenem 1g	q 6-8hrs x 1 dose	24 hours
Penetrating chest injury **with** esophageal disruption	Cefazolin 1- 2g PLUS metronidazole 500 mg IV Or Ertapenem 1g	q 6-8hrs q 8-12hrs x 1 dose	Stop 24 hours after definitive closure
Abdominal Wounds			
Penetrating abdominal injury **with suspected/known** hollow viscus injury and soilage; may apply to rectal/perineal injuries as well	Cefazolin, 1-2g IV PLUS metronidazole 500 mg IV Or Ertapenem 1g	q 6-8hrs q 8-12hrs x 1 dose	Stop 24 hours after control of contamination
Maxillofacial And Neck Wound			
Open maxillofacial fractures, maxillofacial fractures **with** foreign body or fixation device	Cefazolin 1-2g g Or Ertapenem 1g	q 6-8hrs x 1 dose	24 hours
Central Nervous System Wounds			
Penetrating brain injury	Cefazolin 1-2g IV Or Ertapenem 1g	q 6-8hrs x 1 dose	5 days or until CSF leak is closed, whichever is longer
Penetrating brain injury **with** gross contamination with organic debris	Cefazolin 1-2g IV; *Consider* metronidazole 500 mg IV Or Ertapenem 1g	q 6-8hrs q 8-12hrs x 1 dose	5 days or until CSF leak is closed, whichever is longer
Penetrating spinal cord injury	Cefazolin 1-2g IV Or Ertapenem 1g	q 6-8hrs x 1 dose	5 days or until CSF leak is closed, whichever is longer
Penetrating spinal cord injury **with** abdominal cavity is involvement	Cefazolin, 1-2g IV PLUS metronidazole 500 mg IV Or Ertapenem 1g	q 6-8hrs q 8-12hrs x 1 dose	5 days or until CSF leak is closed, whichever is longer
Eye Wounds			
Eye injury, burn or abrasion	Erythromycin ophthalmic ointment Or Bacitracin ophthalmic ointment	q 6hrs or PRN for symptomatic relief	Until epithelium healed. No systemic treatment required
Eye injury, penetrating	Levofloxacin 750 mg IV/PO PLUS vancomycin 15-20 mg/kg IV Or Moxifloxacin 400 mg IV/PO once daily	q 24 hrs q 8-12hrs q 24hrs	7 days or until evaluated by an ophthalmologist. No topical agents.
Burns			
Superficial burns	Topical antimicrobials (mafenide acetate or silver sulfadiazine) OR silver impregnated dressing, PLUS excision and grafting	q 24hrs q 3-5d	Until healed
Deep partial thickness burns	Topical antimicrobials (mafenide acetate or silver sulfadiazine) OR silver impregnated dressing, PLUS excision and grafting	q 24hrs q 3-5d	Until healed or grafted
Full thickness burns	Topical antimicrobials PLUS excision and grafting	q 24hrs	Until healed or grafted
Delayed Evacuation to Surgical Care			
PO tolerable Not PO tolerable	Moxifloxacin 400 mg PO x 1 dose. Or Ertapenem 1 g IV/ IM	X 1 dose X 1 dose	Single dose therapy

Value equals amount of fluid in each ml of dilution

Each ml of medication diluted into your chosen fluid still counts towards total solution volume (i.e. 1ml of drug + 4ml fluid = 5ml solution; 1ml drug + 9ml fluid = 10ml solution). Small volume medications (1-2ml) are inconsequential above dilutions >50ml

1mg=1000mcg	0.1mg=100mcg	0.01mg=10mcg

Vasopressor Priority Chart

	HYPOVOLEMIC SHOCK	SEPTIC SHOCK	CARDIOGENIC SHOCK$_1$	NEUROGENIC SHOCK$_{2,3}$	BURN SHOCK$_4$
1°	**Vasopressors are not recommended in the initial stabilization of hypovolemic shock.**	Norepinephrine	Norepinephrine	Norepinephrine	Vasopressin
2°		Vasopressin	Dobutamine	Epinephrine	Norepinephrine
3°	Norepinephrine	Epinephrine	Epinephrine	Vasopressin	Epinephrine

- **Vasopressors should only be initiated with/after adequate resuscitation is provided with crystalloids, colloids, and/or blood products.**
- **Maintain mean arterial pressure (MAP) 65 mmHg or as needed to achieve adequate end-organ perfusion (e.g. cerebral perfusion pressure, abdominal perfusion pressure, urinary output).**

1. In low output Cardiogenic Shock, dobutamine may be initiated in combination with norepinephrine.
2. Due to the physiologic nature of Neurogenic Shock, vasopressors may be initiated earlier to avoid volume overload.
3. Phenylephrine should be avoided in most Neurogenic Shock patients due to unopposed alpha activity that can result in reflex bradycardia; further worsening spinal cord injury (SCI) associated bradycardia.
4. In Burn Shock casualties at risk of burn fluid over-resuscitation (e.g. 250mL/Kg in the 1st 24 hours), a continuous, non-titratable infusion of Vasopressin at 0.04 Units/minute (2.4 Units/hour) may be initiated to avoid volume overload.

MEDICATION, DRUG CARDS

a. General Use
    i. Use as clinically indicated per guideline.
b. Medications, all:
    ii. If carried, these medications are available for use, within the limitations of these guidelines, drug cards, and supervising medical director / physician. These medications may be used during transfer of critical care patients or during point of injury. These medications are available for use on any patient, within the limitations of these guidelines, as clinically indicated, to address acute life-threatening emergencies not accounted for on the transferring physician's written orders. Some medications utilized during critical care transfer requires written orders and guidance from transferring physician or as directed by unit medical director/supervising physician.

Oxygen

Class: Atmospheric gas.
Mechanism of Action: The essential substrate for cellular respiration.
Duration of action: Onset: immediate. Peak effect: not applicable. Duration: less than 2 minutes.
Indications: All causes of decreased tissue oxygenation and/or decreased level of consciousness. (Confirmed or expected hypoxemia, ischemic chest pain, respiratory, insufficiency, prophylactically during air transport, confirmed or suspected carbon monoxide poisoning). Also provides mechanical work for gas-powered ventilators, if supply and flow rate is sufficient (OBOGS will not work).
Contraindications: Coincidental paraquat inhalation (rare); COPD patients may become hypopneic with high O2 flow rates due to "oxygen baroreceptor respiratory drive (relative contraindication).
Adverse Reactions: Retinopathy of prematurity (prolonged use); potential oxygen toxicity in hyperbaric environments; cerebral vasoconstriction.
Drug Interactions: None
How Supplied: Medical grade Oxygen is 93% O_2 (+/- 3%) under United States Pharmacopeia (USP) Standards. USP Standard O_2 is supplied through compressed gas cylinders (D cylinder) or continuous flow oxygen generator or concentrator systems.
Dosage and Administration:
• Assure adequate ventilation (spontaneous or supported) coincidental to supplemental oxygen therapy, ideally by end-tidal CO_2 measurement (Goal EtCO2 35-45).
• All critically ill and injured transport patients will receive supplemental oxygen to maintain SPO_2 of > 93%.
• Administer oxygen 2-6 LPM via nasal cannula.
    ○ If O2 Saturation remains < 95%, apply non-rebreather face mask with oxygen at 15 LPM.
    ○ If O2 Saturation remains < 90%, refer to **Airway guideline**.
• Patient on Ventilator:
    ○ Adjust ventilator settings based on ventilatory goals for patient: ETCO2, peak pressures, SpO2, and patient clinical condition.
    ○ Adjust FiO2 to maintain pulse oxygen saturations > 93% / tissue oxygen saturation (STO_2) > 70%, if applicable.
• When planning for available O_2 during non-pressurized, aeromedical transfer, ensure adequate resources to provide 1.5 to 2 times the ground transport volume of O_2 to compensate for increased consumption associated with altitude related physiological impact.

0.9% Sodium Chloride (Normal Saline)

Class: Isotonic crystalloid solution.
Mechanism of Action: Replaces water and electrolytes.
Indications: Hypovolemia, Shock, Heat-related injuries, diabetic ketoacidosis, TKO IV, a diluent of choice for blood product transfusion.
Contraindications: Avoid for intravascular volume replacement for hemorrhagic shock due to hemodilution and hyperchloremic metabolic acidosis. Use with caution in patients with known congestive heart failure.
Adverse Reactions: Rare
Drug Interactions: Few in the pre-hospital emergency setting.
How Supplied: 250mL, 500mL, and 1,000mL bags.
Dosage and Administration: The specific situation being treated will dictate the rate in which normal saline will be administered. Hypovolemic shock requires rapid bolus (see relevant guidelines). In other cases, it is advisable to administer the fluid at a moderate rate (for example, 100 mL/h).

Hypertonic Saline 3% Sodium Chloride

Class: Hypertonic crystalloid solution.
Mechanism of Action: Replaces water and electrolytes, increases intravascular sodium concentration, may induce diuresis
Indications: Refractory elevated intracranial pressure (ICP) due to various etiologies (eg, subarachnoid hemorrhage, neoplasm); traumatic brain injury with elevated ICP: (Can be used in place of mannitol).
Contraindications: Do not use in the same line as Blood Products – cause crenation and lysis of RBC. Caution or avoid use in patients with known congestive heart failure and kidney disease.
Adverse Reactions: Rare
Drug Interactions: Few in the pre-hospital emergency setting.
How Supplied: 250mL, 500mL, bags.
Dosage and Administration:

- Dosing (Adult):
    - **Bolus**: 250mL IV Bolus over 15 min.
    - **Infusion**: 50-100 cc/hr
- Dosing (Pediatrics):
    - **Bolus**: 5 cc/kg IV Bolus over 15 min.
    - **Infusion**: 0.5 cc/kg/hr

Ringer's, Lactate (Lactated Ringers/Hartman's Solution)

Class: Isotonic crystalloid solution.
Mechanism of Action: Replaces water and electrolytes.
Indications: Hypovolemic shock; keep open IV.
Contraindications: Should not be used in the same line with blood components. Use with caution for intravascular volume replacement for hemorrhagic shock due to hemodilution and exacerbation of coagulopathy. Use with caution in patients with known congestive heart failure and kidney disease. Can cause lactic acidosis.
Adverse Reactions: Rare
Drug Interactions: Few in the pre-hospital emergency setting.
How Supplied: 250mL, 500mL, and 1,000mL bags. IV infusion.
Dosage and Administration: Hypovolemic shock; titrate according to the patient's physiologic response. (See appropriate Guidelines)

Dextrose 5% in Water (D5W)

Class: Hypotonic dextrose-containing solution.
Mechanism of Action: D5W provides nutrients in the form of dextrose as well as free water.
Indications: IV diluent for certain emergency drugs; for dilution of concentrated drugs for intravenous infusion.
Contraindications: Not for use as fluid replacement for hypovolemic states.
Adverse Reactions: Rare
Drug Interactions: Phenytoin (Dilantin)
How Supplied: Supplied in 50mL, 100mL, 150mL, 250mL, 500mL, and 1,000mL bags.
Dosage and Administration: Normally administered through a mini-drip (60 gtt/mL) set at a rate of "to keep open" (TKO).

PlasmaLyte A

Class: Isotonic crystalloid solution.
Mechanism of Action: Replaces water and electrolytes.
Indications: Hypovolemic shock; compatible with blood or blood components. It may be administered before or following the infusion of blood through the same administration set (i.e., as a priming solution), added to or infused concurrently with blood components, or used as a diluent in the transfusion of packed erythrocytes. PLASMALYTE A and 0.9% Sodium Chloride Injection are equally compatible with blood or blood components.
Contraindications: Use with caution for intravascular volume replacement for hemorrhagic shock due to hemodilution and exacerbation of coagulopathy. Use with caution in patients with known congestive heart failure and kidney disease. Excess administration may result in metabolic alkalosis.
Adverse Reactions: Rare
Drug Interactions: Few in the pre-hospital emergency setting.
How Supplied: 500mL, and 1,000mL bags IV infusion.
Dosage and Administration: Hypovolemic shock; titrate according to the patient's physiologic response. (See appropriate Guidelines)

ACETAMINOPHEN

♀C, **Lactation Yes** (Caution)

Trade Name: **Tylenol**

Class / Mechanism of Action

Analgesic

Blocks cyclooxygenase (COX 1 and 2) enzymes, resulting in reduced formation of prostaglandin precursors. Blocks formation of prostaglandin derivative, thromboxane A2, resulting in inhibited platelet aggregation. Has antipyretic, analgesic, and anti-inflammatory properties.

Indications

Labeled Indications: Treatment of mild to moderate pain and fever, Treatment of moderate to severe pain when provided via IV with opioid analgesia

Contraindications

- Hypersensitivity to acetaminophen or any component of the formulation
- Hepatic impairment or liver disease

Adverse Reactions / Precautions

- Use IV form cautiously in volume depleted patients
- Avoid use in patient suffering alcohol toxicity, known alcohol abuse, or renal impairment
- IV form can cause nausea and vomiting (especially in adults), headache

Dose and Administration:

ADULT

Pain or fever: (Limit total daily dose to <4 g/day

PO:

- Regular release: **325-650 mg** every 4-6 hours or **1000 mg** 3-4 times daily (maximum: 4 g daily)

RECTAL:

- **325-650 mg** every 4-6 hours or **1000 mg** 3-4 times daily (maximum: 4 g daily)

IV:

- <50 kg**: 15 mg/kg** every 6 hours
  - Max single dose: 15 mg/kg/dose (750 mg/dose)
  - Max daily dose: 75 mg/kg/day (≤3.75 g daily)
- ≥50 kg**: 1000** mg every 6 hours
  - Max single dose: 1000 mg/dose

PEDIATRIC Always Reference BROSELOW Tape

Pain or fever: Children ≥12 years & Adolescents: Refer to adult dosing

PO:

- Infants and Children <12 years**: 10-15 mg/kg/dose** every 4-6 hours as needed; do not exceed 5 doses (2.6 g) in 24 hours

RECTAL:

- Infants and Children <12 years**: 10-20 mg/kg/dose** every 4-6 hours as needed; do not exceed 5 doses (2.6 g) in 24 hours.

IV:

- Children 2-12 years: **15 mg/kg** every 6 hours or **12.5 mg/kg** every 4 hours
  - Max single dose: 15 mg/kg/dose (≤750 mg/dose)
  - Max daily dose: 75 mg/kg/day (≤3.75 g daily)

ACETAZOLAMIDE

♀C, **Lactation Yes**(Caution)

Trade Name: **Diamox**

Class / Mechanism of Action

Diuretic, Carbonic Anhydrase Inhibitor; Anticonvulsant

Inhibits carbonic anhydrase causing a decrease in hydrogen ion renal secretion with increased renal secretion of sodium, potassium, bicarbonate, and water. Onset of action PO: 2 hours, IV 5-10 minutes

Indications

Labeled Indications:

- Prevention or treatment of symptoms of acute mountain sickness
- Edema due to congestive heart failure

Contraindications

- Hypersensitivity to acetazolamide, sulfonamides, or any component of the formulation
- Confirmed low sodium / potassium levels otherwise none in emergency setting

Adverse Reactions / Precautions

- May worsen respiratory acidosis
- Drowsiness, deceased alertness, impairment of coordination, nausea, headache
- Flushing of skin, allergic skin reaction, skin photosensitivity

Dose and Administration:

ADULT

Altitude illness (Acute Mountain Sickness):

PO:

- **125-250 mg** twice daily.

Note: For high altitude cerebral edema (HACE), dexamethasone is the primary treatment; however, acetazolamide can be used (together with dexamethasone) at the AMS dose.

Edema (Only with referring doctor or medical director instruction):

PO, IV:

- **250-375 mg** once daily

PEDIATRIC Always Reference LB tape

Altitude illness (Acute Mountain Sickness):

PO: (IM not recommended due to alkaline pH)

- **2.5 mg/kg/dose** every 8-12 hours
  - MAX dose 250mg/dose.

Note: For high altitude cerebral edema (HACE), dexamethasone is the primary treatment; however, acetazolamide can be used (together with dexamethasone) at the AMS dose.

ACETYLSALICYLIC ACID

♀C, **Lactation Yes** (Short Term or Low Dose OK)

Trade Name: **Aspirin**

Class / Mechanism of Action

Nonsteroidal Anti-inflammatory Drug (NSAID)

Blocks cyclooxygenase (COX 1 and 2) enzymes, resulting in reduced formation of prostaglandin precursors. Blocks formation of prostaglandin derivative, thromboxane A2, resulting in inhibited platelet aggregation. Has antipyretic, analgesic, and anti-inflammatory properties.

Indications

Labeled Indications: Treatment of acute coronary syndromes (ST-elevation MI, non-ST-elevation MI, unstable angina), acute ischemic stroke, and transient ischemic episodes.

Contraindications

- Hypersensitivity to salicylates, other NSAIDs, or any component of the formulation
- Asthma, Rhinitis
- Inherited or acquired bleeding disorders (including factor VII and factor IX deficiency)
- Do not use in children less than 16 years old (Reye's syndrome)

Adverse Reactions / Precautions

- Not for use on trauma patients in the combat environment.
- Risk of bleeding: Avoid use in patients with known or suspected: Bleeding disorders, GI Bleed, GI Ulcers, patients taking Coumadin, or within 24hrs of taking Alteplase (tPA) for suspected stroke

Dose and Administration:

ADULT	PEDIATRIC Always Reference BROSELOW Tape
Acute coronary syndrome (ST-segment elevation myocardial infarction [STEMI], unstable angina (UA)/non-ST-segment elevation myocardial infarction [NSTEMI]): (Not for use in trauma patients): PO: • **324 mg** (chew nonenteric-coated aspirin as a single 325 mg tablet or 4 X 81 mg tablets)	**N/A:** **Contraindicated in children under 16 yrs (Reye's Syndrome)**

ACTIVATED CHARCOAL ♀Safe, Lactation Safe Trade Name: **Actidose**

Class / Mechanism of Action

Antidote

Non-absorbable agent that absorbs toxins within the GI tract inhibiting GI absorption.

Indications

Labeled Indications: Management of suspected or known poisonings when gastrointestinal decontamination is an option.

- Decontamination within 1 hour of ingestion of toxic substance

Contraindications

- Presence of intestinal obstruction or GI tract not anatomically intact
- Patients at risk of GI hemorrhage or perforation
- Patients with an unprotected airway (eg, CNS depression without intubation) or if use would increase the risk and severity of aspiration

Adverse Reactions / Precautions

- If patient unconscious, must establish airway control and must utilized NG/OG tube.
- Be prepared for possible emesis. Consider use of antiemetic.
- Avoid use in patients at risk of GI hemorrhage or perforation

Dose and Administration: ADULT	**PEDIATRIC** Always Reference BROSELOW Tape
Acute Poisoning: PO,NG/OG: • Single dose: **50 grams** • Multidose: After initial **50 gram** dose, follow with **25 grams** every 2 hours **Note:** Activated Charcoal has limited efficacy if not utilized within 1 hour of toxin ingestion. Risk-benefit of charcoal must seriously be considered because it does not work for all poisons, it must be given early when the poison is still in the stomach, it does not fully bind all poisons, and serious complications can occur with aspiration. Aspiration can occur if deteriorating mental status and/or vomiting. **Note:** Some products may contain sorbitol. Co-administration of a cathartic, including sorbitol, is no longer recommended. **Note:** Multidose charcoal is indicated if patient ingested a life-threatening amount of drug (carbamazepine, dapsone, phenobarbital, guanine, or theophylline)	**Acute Poisoning:** Children >12 years: Refer to adult dosing. PO,NG/OG: • Single dose: **1 gram/kg** • Multidose: Initial dose: **1Gram/kg** initially, followed by multiple doses of **0.5 Gram/kg** every 2 hours **Note:** Some products may contain sorbitol. Co-administration of a cathartic, including sorbitol, is no longer recommended. **Note:** Activated Charcoal has limited efficacy if not utilized within 1 hour of toxin ingestion.

ADENOSINE

♀C, Lactation Yes (Caution)

Trade Name: **Adenocard®**

Class / Mechanism of Action

Antiarrhythmic Agent

Slows conduction time through the AV node, inhibits re-entry pathways through the AV node, restoring normal sinus rhythm. The half-life of under 10 seconds allows for rapid repeat dosing.

Indications

Labeled Indications: Paroxysmal supraventricular tachycardia (PSVT) when clinically advisable, vagal maneuvers should be attempted first; not effective for conversion of atrial fibrillation, atrial flutter, or ventricular tachycardia.

Unlabeled: ALS/PALS Guidelines (2020): Stable, narrow-complex regular tachycardias; unstable narrow-complex regular tachycardias while preparations are made for synchronized direct-current cardioversion; stable regular monomorphic, wide-complex tachycardia as a therapeutic (if SVT) and diagnostic maneuver.

Contraindications

- Hypersensitivity to adenosine or any component of the formulation
- Second- or third-degree AV block, sick sinus syndrome, or symptomatic bradycardia (except in patients with a functioning artificial pacemaker)
- Use in patients with atrial fibrillation/flutter with underlying Wolff-Parkinson-White (WPW) syndrome (Fuster, 2006); asthma (ALS, 2020)
- Known or suspected bronchoconstrictive (Asthma) or bronchospastic lung disease.

Adverse Reactions / Precautions

- May cause transient asystole and new arrhythmia after cardioversion (PACs, AF, PVCs) chest discomfort
- Headache, Dizziness, Flushing, GI upset
- Dyspnea, Bronchospasm in asthmatics

Dose and Administration:

ADULT

Paroxysmal supraventricular tachycardia:

I.V. (rapid push, over 1-2 seconds, via proximal peripheral line (forearm or above, large bore).

- Initial: **6 mg;** if not effective within 1-2 minutes, **12 mg** may be given if needed (maximum single dose: 12 mg).

Notes): Follow each dose with **20 mL** normal saline flush.

Note: Initial dose of adenosine should be reduced to 3 mg if patient is currently receiving carbamazepine or dipyridamole, has a transplanted heart or if adenosine is administered via central line (ALS, 2020).

Note: Adenosine effects are antagonized by caffeine and theophylline, and patients may require higher doses.

PEDIATRIC Always Reference BROSELOW Tape

Paroxysmal supraventricular tachycardia:

IV/IO as close to core as possible (rapid push, over 1-2 seconds, see **Note**): Follow each dose with 10-20 mL normal saline flush..

- Initial: **0.1 mg/kg** (maximum initial dose: 6 mg); if not effective within 1-2 minutes, administer **0.2 mg/kg** (maximum single dose: 12 mg). Follow each dose with 5-10 mL normal saline flush.

ALBUTEROL

♀C, Lactation Yes

Trade Name: **Proventil / Ventolin**

Class / Mechanism of Action

Beta$_2$ Agonist (Bronchodilator)

Synthetic sympathomimetic that relaxes bronchial smooth muscle, causing bronchodilation, with little cardiac impact. Onset of action is 2-15 minutes

Indications

Labeled Indications: Treatment or prevention of bronchospasm in patients with reversible obstructive airway disease; prevention of exercise-induced bronchospasm

- Asthma
- Reactive Airway / Bronchospasm
- COPD
- May also be used in Crush Syndrome (Hyperkalemia)

Contraindications

- Hypersensitivity to albuterol or any component of the formulation
- Symptomatic tachycardia

Adverse Reactions / Precautions

- Risk of abortion during 1st or 2nd trimester
- Headache, Dizziness, Flushing, Diaphoresis, Tremor, Weakness
- Angina, A-Fib, Arrhythmia, Chest Pain, Palpitations
- Dyspnea, Bronchospasm in asthmatics

Dose and Administration:

ADULT

Bronchospasm:

Metered-dose inhaler (90 mcg/puff):

- **2 puffs** every 4-6 hours as needed

Solution for nebulization:

- **2.5 mg** 3-4 times daily as needed

Exacerbation of asthma (acute, severe):

Metered-dose inhaler:

- **4-8 puffs** every 20 minutes for up to 4 hours, then every 1-4 hours as needed

Solution for nebulization:

- **2.5-5 mg** every 20 minutes for 3 doses, then **2.5-10 mg** every 1-4 hours as needed.

PEDIATRIC Always Reference BROSELOW Tape

Bronchospasm:

Metered-dose inhaler (90 mcg/puff):

- **4-8 puffs** every 4-6 hours as needed

Solution for nebulization:

- Children ≤4 years: **2.5 mg** every 4-6 hours as needed
- Children ≥5 years: **2.5-5 mg** every 4-8 hours as needed
- Children ≥12 years: Refer to adult dosing.

Exacerbation of asthma (acute, severe):

Metered-dose inhaler (90 mcg/puff):

- Children <12 years: **4-8 puffs** every 20 minutes for 3 doses, then every 1-4 hours as needed
- Children ≥12 years: Refer to adult dosing.

Solution for nebulization:

- Children <12 years: **0.15 mg/kg** (minimum: 2.5 mg) every 20 minutes for 3 doses, then **0.15-0.3 mg/kg** (maximum: 10 mg) every 1-4 hours as needed
- Children ≥12 years: Refer to adult dosing.

AMIODARONE

♀**D, Lactation: Yes,** Not Recommended

Class / Mechanism of Action

Antiarrhythmic Agent, Class III

Inhibits adrenergic stimulation (alpha and beta blocking), prolongs action potential and refractory period (prolongs PR and QT intervals); decreases AV conduction and sinus node function (decreases sinus rate)

Indications

Labeled Indications: Management of life-threatening recurrent ventricular fibrillation (VF) or hemodynamically unstable ventricular tachycardia (VT) refractory to other antiarrhythmic agents

Unlabeled:

- Recurrent, hemodynamically unstable VT. (after other drugs have failed)
- Ventricular tachyarrhythmias (ACLS/PALS 2015): VF/VT Cardiac arrest unresponsive to CPR, Shock, and Vasopressor.

Contraindications

- Hypersensitivity to amiodarone, iodine, or any component of the formulation
- Severe sinus-node dysfunction
- 2nd and 3rd degree heart block (except in patients with a functioning artificial pacemaker)
- Bradycardia causing syncope (except in patients with a functioning artificial pacemaker)
- Cardiogenic shock

Adverse Reactions / Precautions

- **Complex drug with multiple complex drug reactions! (Do not administer with procainamide)**
- Hypotension
- Dizziness, fatigue, Headache, Poor coordination, Neuropathy
- Nausea, Vomiting
- Dysrhythmias, Asystole, AF, Bradycardia, AV block, Conduction abnormalities, SA node dysfunction

Dose and Administration:

ADULT

Pulseless VT or VF (ACLS, 2015):

IV/IO push

- **300 mg** rapid bolus; should be diluted in 30 mL of NS, Plasmalyte, or D5W; if pulseless VT or VF continues after subsequent defibrillation attempt or recurs, administer **supplemental dose of 150 mg.**

Recurrent, Hemodynamically unstable VT (ACLS, 2015):

Initial Dose:

IV/IO slow push

- **150mg IV** over 1st 10 minutes (15mg per minute) dilute in 100 ml of NS, PlasmaLyte, or D5W (concentration 1.5mg/ml).
- May repeat **150 mg** every 10 minutes PRN if VT recurs

Maintenance Infusion following initial dosing:

- **360 mg** over 6 hours (1 mg/ min) dilute in 500ml of NS, PlasmaLyte, or D5W (concentration 0.72 mg/ml).

PEDIATRIC Always Reference BROSELOW Tape

Pulseless VT or VF (PALS, 2015):

IV/IO push

- **5mg/kg** IV bolus during cardiac arrest, May repeat twice for refractory VF/pulseless VT.
- Max single dose: 300mg

Tachycardia with Pulse and poor perfusion, or symptomatic with adequate perfusion (PALS, 2015):

IV/IO push

- Loading dose: **5mg/kg** over 20 to 60 minutes (Fast push or bolus can precipitate cardiac failure!)
- Can repeat two times (max dose: 15 mg/kg in 24 hrs)
- Max single dose: 300mg

AMIODARONE					
Initial Dose: 15mg/min over 10 min (150mg over 10min)					
MIX 150 mg/100 mL CONCENTRATION 1.5 mg/mL					
Dose	Rate	Micro (60	Macro		
			20 gtt/mL	15 gtt/mL	10 gtt/mL
mg/min	mL/min	gtt/min	gtt/min	gtt/min	gtt/min
15	10	600	200	150	100
Macro-Drip (10gtt/ml) is set of choice for this infusion					
Set rate provides complete initial infusion of 150mg over 10 minutes. May repeat Q 10 min PRN if VT recurs					

Maint Dose: 1mg/min over 6 hrs (360mg over 360min)					
MIX 360 mg/500 mL CONCENTRATION 0.72 mg/mL					
Dose	Rate	Micro (60	Macro		
			20 gtt/mL	15 gtt/mL	10 gtt/mL
mg/min	mL/min	gtt/min	gtt/min	gtt/min	gtt/min
1	1.4	84	28	21	14
Macro-Drip (20gtt/ml) is set of choice for this infusion					
Set rate provides maintenance infusion of 360mg over 6hrs.					

ATROPINE Sulfate

♀C, **Lactation: Yes,** Use Caution

Trade Name: **AtroPen**

Class / Mechanism of Action

Anticholinergic, Antidysrhythmic, Antidote for Carbamate Anticholinesterase poisoning

Blocks acetylcholine at parasympathetic sites in smooth muscle, secretory glands, and the CNS; increases cardiac output, and dries secretions. Atropine reverses the muscarinic effects of cholinergic poisoning. Reverses bronchorrhea and bronchoconstriction, but does not affect the nicotinic receptors responsible for muscle weakness, fasciculations, and paralysis.

Indications

Labeled Indications: Treatment of

- Symptomatic Sinus Bradycardia, AV block (nodal level)
- Antidote for anticholinesterase poisoning (carbamate insecticides, nerve agents, organophosphate insecticides)

Contraindications

- Hypersensitivity to atropine or any component of the formulation
- Narrow-angle glaucoma; adhesions between the iris and lens (ophthalmic product)
- Pyloric stenosis
- Prostatic hypertrophy
- **Note:** NO contraindications should prevent use of atropine in setting of life threatening organophosphate, carbamate, or nerve agent poisoning

Adverse Reactions / Precautions

- Tachycardia and arrhythmia (VTach, VFib), Hypotension, Palpitations
- Dilated Pupils, Angle-closure glaucoma
- Headache, Dry Mouth, constipation, urinary retention, flushing
- **Paradoxical Bradycardia noted with doses less than 0.1mg**

Dose and Administration: **ADULT** | **PEDIATRIC** Always Reference BROSELOW Tape

Symptomatic Bradycardia

IV/IO

- **1 mg** every 3-5 minutes, not to exceed a total of 3 mg or 0.04 mg/kg (ARC, 2020)

Organophosphate or carbamate insecticide or nerve agent poisoning:

IV/IM: (Used with 2-Pam Chloride auto injector)

- *Initial:* 1-6 mg; repeat every 3-5 minutes as needed, doubling the dose if previous dose did not induce atropinization. Maintain with repeat doses as needed for ≥ 2-12 hours based on recurrence of symptoms.

IM *(**AtroPen®**):* anterolateral aspect of thigh and hold in place for 10 seconds. Follow with 2-Pam Chloride auto injector.

- Mild symptoms (≥2 mild symptoms): **2 mg** once an exposure is known or strongly suspected.
- Severe symptoms (≥1 severe symptom): **Three** 2 mg doses in rapid succession.

Mild and Severe Symptoms are noted on product labeling and **Pralidoxime Chloride** drug card.

Symptomatic Bradycardia

IV/IO

- **0.02 mg/kg** (Minimum dose is 0.1 mg. Maximum single dose of 0.5 mg. May repeat once in 3-5 minutes. Maximum total dose is 1 mg (PALS, 2020)

Organophosphate or carbamate insecticide:

- IV/IO: Initial: **0.05-0.1 mg/kg**; repeat every 5-10 minutes as needed, double dose if previous dose does not induce atropinization. Maintain with repeat doses as needed for ≥2-12 hours based on recurrence of symptoms.

Severe Nerve Agent Poisoning:

- IV/IO 1mg every 3 min. Monitor Patient for signs and symptoms of atropinization, (drying up of secretions). Once clinical improvement is achieved restrict to 10-20% of original dose (approximately 2-4mg/hr)

CALCIUM Chloride 10% ♀Safe, Lactation Safe

Class / Mechanism of Action

Calcium Salt, Electrolyte Supplement
Moderates nerve and muscle contractility via action potential excitation threshold regulation

Indications

Labeled Indications: Treatment of hypocalcemia and conditions secondary to hypocalcemia (eg, tetany, seizures, arrhythmias); emergent treatment of severe hypermagnesemia; massive transfusion prophylaxis
Unlabeled: Calcium channel blocker overdose; beta-blocker overdose (refractory to glucagon and high-dose vasopressors); severe hyperkalemia (K+ >6.5 mEq/L with toxic ECG changes) [ALS guidelines]; malignant arrhythmias (including cardiac arrest) associated with hypermagnesemia [ALS guidelines]

Contraindications

- Known or suspected digoxin toxicity
- Not recommended as routine treatment in cardiac arrest (includes asystole, ventricular fibrillation, pulseless ventricular tachycardia, or pulseless electrical activity)
- Hypercalcemia

Adverse Reactions / Precautions

- Hypokalemia: Use with caution in patients with severe hypokalemia. Acute rises in calcium can cause life-threatening arrhythmias
- Rapid push can cause: Arrhythmia, bradycardia, cardiac arrest, hypotension, syncope, vasodilation
- **Use small IV / Large Vein, flush prior and after, AVOID Extravasation** (will cause tissue necrosis)
  - In general, IV Calcium Gluconate is preferred over IV Calcium Chloride in nonemergency settings due to the potential for extravasation with calcium chloride
- **Do not infuse calcium chloride in the same I.V. line as phosphate-containing solutions.**
- Precipitates with $NaHCO_3$ in IV Bag/Tubing

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

ADULT

Cardiac arrest or cardiotoxicity in the presence of hyperkalemia, hypocalcemia, or hypermagnesemia: IV/IO, **SLOW**

- **500-1000 mg** over 2-5 minutes

Beta-blocker overdose, refractory to glucagon and high-dose vasopressors (unlabeled use): IV/IO

- **20 mg/kg** over 5-10 minutes followed by an infusion of 20 mg/kg/hour titrated to adequate hemodynamic response

Calcium channel blocker overdose (unlabeled use) (CaCl preferred over Calcium Gluconate for this use**):** IV/IO

- Initial: **1000mg** over 5 minutes; may repeat every 10-20 minutes with 3-4 additional doses; or a continuous infusion of 2-6 grams/hour may be initiated

Hypocalcemia prophylaxis from massive transfusion

- **10ml (10cc) 10% solution** over 5 minutes

Damage Control Resusitation: IV/IO, **SLOW**
1000 mg after 1st blood unit and after every 4th unit

PEDIATRIC

Cardiac arrest or cardiotoxicity in the presence of hyperkalemia, hypocalcemia, or hypermagnesemia:
IV/IO, **SLOW**

- **20 mg/kg** (maximum: 2000 mg/dose); may repeat as necessary

Calcium channel blocker overdose (unlabeled use):
IV/IO

- Initial: **20 mg/kg** (0.2ml/kg) (maximum: 1000 mg/dose) over 10-15 minutes; may repeat every 10-15 minutes

Note: Adult and Pediatric dosages are expressed in terms of the calcium chloride salt based on a solution concentration of 100 mg/mL (10%) containing 1.4 mEq (27 mg)/mL elemental calcium. (1gram = 10cc of a 10% solution)

Note: Calcium Chloride is 3X more potent than Calcium Gluconate and therefore lower doses of Calcium Chloride must be used to reach similar therapeutic doses

CALCIUM Gluconate ♀Safe, Lactation Safe

Class / Mechanism of Action

Calcium Salt, Electrolyte Supplement
Moderates nerve and muscle contractility via regulation of action potential excitation threshold.

Indications

Labeled Indications: Treatment of hypocalcemia and conditions secondary to hypocalcemia (e.g, tetany, seizures, arrhythmias); cardiac disturbances secondary to hyperkalemia; magnesium sulfate overdose; massive transfusion prophylaxis
Unlabeled: Calcium channel blocker overdose; treatment of hydrofluoric acid exposure

Contraindications

- Ventricular fibrillation
- Hypercalcemia
- Concomitant use of IV calcium gluconate and ceftriaxone in neonates (risk of precipitation of calcium-ceftriaxone)

Adverse Reactions / Precautions

- Hypokalemia: Use with caution in patients with severe hypokalemia. Acute rises in calcium can cause life-threatening arrhythmias
- Rapid push can cause: Arrhythmia, bradycardia, cardiac arrest, hypotension, syncope, vasodilation
  - Do not exceed 200mg/min except in emergency situations
- Caution in patients receiving digoxin therapy, may cause arrhythmias
- **Use small IV / Large Vein, flush prior and after, AVOID extravasation** (will cause tissue necrosis)
  - In general, IV Calcium Gluconate is preferred over I.V. calcium chloride in nonemergency settings due to the potential for extravasation with calcium chloride
- **Do not infuse calcium chloride in the same I.V. line as phosphate-containing solutions.**
- Precipitates with $NaHCO_3$ in IV Bag/Tubing

Dose and Administration: ADULT

Cardiac arrest or cardiotoxicity in the presence of hyperkalemia, hypocalcemia, or hypermagnesemia:
IV/IO, **SLOW**

- **1500-3000mg** over 2-5 minutes

Calcium channel blocker overdose (off-label use):
Hypotension/conduction disturbances:
IV/IO

- **3 Grams** (3000mg) over 5 minutes; may repeat every 10-20 minutes with 3-4 additional doses.

Hypocalcemia prophylaxis from massive transfusion

- **30mL of 10% solution** over 5 minutes
  Note: Calcium Chloride is 3X more potent than Calcium Gluconate and therefore higher doses of Calcium Gluconate must be used to reach similar therapeutic doses.

Hydrofluoric Acid Exposure – (off-label, see Burn SMOG)

- Topical therapy: After **thorough irrigation**, a CaGlu gel (75mL KY Jelly + 25mL 10% CaGlu) can be made and applied to the affected area, left on for 30 minutes, cleaned off, and repeated every 4 hours. Assess for pain relief and monitor EKG. (NO Calcium Chloride!)

Dose and Administration: PEDIATRIC Always Reference BROSELOW Tape

Cardiac arrest or cardiotoxicity in the presence of hyperkalemia, hypocalcemia, or hypermagnesemia:
IV/IO, **SLOW**

- **60-100 mg/kg/dose** (maximum: 3000 mg/dose)

Calcium channel blocker overdose (unlabeled use): *Hypotension/conduction disturbances:*
IV/IO

- **45 mg/kg** (maximum 3000mg/dose) over 10-15 minutes; may repeat every 10-15 minutes

Hypocalcemia prophylaxis from massive transfusion

- **60mg/kg (maximum 30ml of 10% solution) over 5 minutes**

Note: Calcium chloride may provide a more rapid increase of ionized calcium in critically ill children.

CEFAZOLIN

♀C, Lactation Yes

Trade Name: **Ancef**

Class / Mechanism of Action

Antibiotic (Cephalosporin 1st Gen)

Bacteriocidal - Inhibits bacterial cell wall synthesis by binding to one or more of penicillin-binding proteins which inhibits cell wall biosynthesis, causing bacteria to eventually lyse.

Indications

Labeled Indications: Used for infection control prophylaxis for traumatic open injuries and surgical prophylaxis.

Contraindications

- Hypersensitivity to cefazolin, other cephalosporin antibiotics, other beta-lactams, or any component of the formulation
- Some cross reactions occur in those with penicillin allergies. Use with caution.

Adverse Reactions / Precautions

- Superinfection – prolonged use may result in fungal or bacterial superinfection (including C.Difficile)
- Increased INR (bleeding risk) – especially in nutritionally-deficient, hepatic/renal disease, prolonged treatment

Dose and Administration:

ADULT

Infection Control:

Routine dosing may be based on body mass:

1g if weight <80kg

2g if weight 81-160 kg (177-352 lbs),

3g if weight > 160 kg (>352 lbs)

Max dose is 12g per day

War wounds (dirty wounds), 2g in 250 mL NS IV over 5 min every 8 hours for 24 hours is adequate for most dirty wounds of the head and neck, torso, and extremities.

IV:

Adults:

- 1-2g every 6-8hrs
  - Max daily dose: 12 g/day

PEDIATRIC

Infection Control:

IV:

Pediatrics:

- 20-30 mg/kg IV q6-8h (maximum, 100 mg/kg/day)
  - Max daily dose: 100 mg/kg/day

DEXAMETHASONE ♀C, Lactation ?(Not Recommended) Trade Name: **Decadron**

Class / Mechanism of Action

Systemic Corticosteroid
Anti-inflammatory, Immunosuppressant Onset of action, IV: Prompt; Duration IV: 72 hours

Indications

Labeled Indications:

- Anti-inflammatory or immunosuppressant in treatment of a variety of diseases: allergic, dermatologic, endocrine, hematologic, inflammatory, neoplastic, renal, respiratory, rheumatic, and autoimmune
- Management if cerebral edema

Unlabeled:

- Treatment of acute mountain sickness (AMS) and high altitude cerebral edema.

Contraindications

- Hypersensitivity to dexamethasone or any component of the formulation
- Systemic fungal infection, cerebral malaria

Adverse Reactions / Precautions

- Not for use in treatment of head injury; increased mortality has occurred in head injury patients treated with high dose IV methylprednisolone. Corticosteroids should not be used in head injuries.

Dose and Administration: **ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
Acute mountain sickness (AMS)/high altitude cerebral edema (HACE) (unlabeled use): PO, IM, IV: • AMS: **4 mg** every 6 hours • HACE: **8 mg** as a single dose; followed with: 4 mg every 6 hours until symptoms resolve	**Acute mountain sickness (AMS)/high altitude cerebral edema (HACE)** (unlabeled use): PO, IM, IV: • **0.15 mg/kg/dose** every 6 hours ○ consider use in high altitude pulmonary edema because of associated HACE with pulmonary edema

DEXTROSE 50% ♀C, Lactation? Trade Name: **Glutose / B-D Glucose**

Class / Mechanism of Action

Antidote, Hypoglycemia

Basic source of calories (fuel) for the body and brain, regulated by insulin. Rapidly increases blood glucose, decreases protein and nitrogen loss, preventing ketosis, and promotes glycogen deposition in liver.

Onset of action: Treatment of hypoglycemia Oral dose: 10 minutes

Maximum effect: Treatment of Hyperkalemia IV: 30 minutes

Indications

Labeled Indications: Treatment of:

- Hypoglycemia: Doses may be repeated in severe cases
- Hyperkalemia: (Must be used in combination WITH Insulin)

Contraindications

- Known Hyperglycemia, otherwise None in the Pre-hospital setting

Adverse Reactions / Precautions

Most adverse effects associated with excessive dose or infusion rate

- If evidence of malnutrition or alcohol abuse, thiamine should be given 1st
- **Tissue Necrosis if Extravasation occurs**; immediately D/C and change IV site
- Hyperglycemia
- Hypokalemia
- Hyponatremia

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Hypoglycemia:

Oral:

- **4-20 g** as a single dose; may repeat if necessary

IV:

- **10-25 g** (40-100 mL of 25% solution or 20-50 mL of 50% solution)

Note: Society of Critical Care Medicine recommends: Treat blood glucose <70 mg/dL (<100 mg/dL in patients with neurologic injury) immediately by stopping insulin therapy (if receiving) and administering 10-20 g (20-40 mL of 50% solution) IV; repeat blood glucose measurement in 15 minutes with repeat dextrose as needed; **avoiding overcorrection**.

Hypoglycemia:

Oral:

- **4-20 g** as a single dose; may repeat if necessary

IV:

- Newborns: **5ml/kg D10** (Max 25 G/dose)
- Infants and Children: **2ml/kg D25** (Max 25 G/dose)
- Adolescents: Refer to adult dosing

Note:

- **D25**= 25ml NS + 25ml D50 (12.5g in 50ml's solution)
- **D10**= 100ml NS + 25ml D50 (12.5g in 125ml's solution)
  or
  40ml NS + 10ml D50 (5g in 50ml's solution)

DIAZEPAM

♀**D, Lactation Yes** (Unsafe) Trade Name: **Valium**

Class / Mechanism of Action

Benzodiazepine;
Acts as an Anxiolytic/Hypnotic, anticonvulsant and sedative – Long Half Life (25-100hrs)
Onset of action: IV, Almost Immediate
Duration: IV, 20-30 minutes

Indications

Labeled Indications:

- Anxiety Disorders
- Convulsive Disorders and Alcohol Withdrawal Symptoms
- Skeletal Muscle Relaxant
- Induce Sedation and Amnesia (Midazolam is primary medication)

Contraindications

- Hypersensitivity to diazepam or any component of the formulation or other benzodiazepines
- Acute narrow angle glaucoma , Acute Alcohol Intoxication
- Respiratory Insufficiency/Depression **(Overdose Reversal: FLUMAZENIL** can be used, however it carries elevated risk. Respiratory support until the medication is metabolized is traditionally the best care in Benzodiazepine overdose**)**
- Neurologic Depression (Head Trauma)

Adverse Reactions / Precautions

- **No Analgesic properties** (Narcotic pain control is needed for RSI'd / Intubated trauma patients)
- May Cause Respiratory depression: Do not give without stable IV line and BVM (airway control) ready
- Hypotension, vasodilation
- Amnesia, confusion, drowsiness, slurred speech (Paradoxical Reactions possible: aggressiveness, agitation, anxiety, inappropriate behavior)

Dose and Administration:

ADULT

Anxiety:
Oral, IV, IM: (Oral and IV doses more reliable)

- **2-10 mg** 2-4 times/day if needed

Status Epilepticus:
IV: (SLOW)

- **5-10 mg** every 5-10 minutes given over 3 minutes (maximum dose: 30 mg)

Sedation in ICU patient:
IV:

- Loading dose: 5-**10 mg;** Maintenance dose: **0.03-0.1 mg/kg** every 30 minutes to 6 hours

Muscle Spasm:
IV:

- Initial: **5-10 mg**; then 5-10 mg in 3-4 hours, if necessary. Larger doses may be required if associated with tetanus.

Nerve Agent Exposure (CBRNE)
IM:

- **10mg** for seizures associated with Nerve Agent exposure; or if 3 MARK 1 kits were used on a casualty

PEDIATRIC Always Reference BROSELOW Tape

Sedation / Muscle relaxation / Anxiety :
IV, IM (IV doses more reliable)

- Children: **0.04-0.3 mg/kg/dose** every 2-4 hours to a maximum of 0.6 mg/kg within an 8-hour period if needed

Status Epilepticus:
IV:

- Infants >30 days and Children <5 years: **0.2-0.5 mg** given slowly every 2-5 minutes (maximum total dose: 5 mg); repeat in 2-4 hours if needed
- Children ≥5 years: **1 mg** given slowly every 2-5 minutes (maximum total dose: 10 mg); repeat in 2-4 hours if needed

Muscle spasm associated with tetanus:
IV, IM

- Infants >30 days and Children <5 years: **1-2 mg/dose** every 3-4 hours as needed
- Children ≥5 years: **5-10 mg/dose** every 3-4 hours as needed

DILTIAZEM

♀C, **Lactation?**(Not Recommended) Trade Name: **Cardizem**

Class / Mechanism of Action

Calcium Channel Blocker; Antiarrhythmic Agent, Class IV

Inhibits calcium ion from entering the "slow channels" or select voltage-sensitive areas of vascular smooth muscle and myocardium during depolarization; produces relaxation of coronary vascular smooth muscle and coronary vasodilation; increases myocardial oxygen delivery in patients with vasospastic angina. Onset of action: IV: 3 minutes, Duration 1-3 hours

Indications

Labeled Indications: Atrial fibrillation or atrial flutter for acute ventricular rate control, conversion of supraventricular tachycardia, hypertension, chronic stable angina, vasospastic angina.

Unlabeled: Hypertrophic cardiomyopathy; Idiopathic ventricular tachycardia; Nonsustained ventricular tachycardia or ventricular premature beats, symptomatic; Pulmonary arterial hypertension (group 1).

Contraindications

- Sick sinus syndrome (except in patients with a functioning artificial pacemaker); Second- or third-degree AV block
- Atrial fibrillation or flutter associated with accessory bypass tract (WPW, short PR syndrome)
- Severe hypotension; Cardiogenic shock; Hypersensitivity to diltiazem or any formulation component
- Ventricular tachycardia (with wide-complex tachycardia [QRS ≥0.12 seconds], must determine whether origin is supraventricular or ventricular)

Adverse Reactions / Precautions

- Cardiovascular: Edema, atrioventricular block, bradycardia, hypotension, dyspnea
- Central nervous system: Headache, dizziness, pain, nervousness, vomiting, weakness, myalgia

Dose and Administration: ADULT

Atrial fibrillation or atrial flutter, rate control:

Note: For rate control in hemodynamically stable patients. Do **not** use in patients with preexcitation associated with an accessory pathway, as this can lead to ventricular arrhythmias.

IV:

- Bolus dose: 0.25 mg/kg (actual body weight) over 2 minutes (average dose: 20 mg); if rate control is insufficient after 15 minutes, a repeat bolus dose of 0.35 mg/kg over 2 minutes may be given (average dose: 25 mg). Patients who respond after 1 or 2 bolus doses can be started on a continuous infusion.
- Continuous infusion following bolus(es): Initial: 5 to 10 mg/hour; infusion rate may be increased in 5 mg/hour increments according to ventricular response, up to a maximum of 15 mg/hour.

Supraventricular tachycardia (alternative agent):

Note: For hemodynamically stable patients if vagal maneuvers and/or adenosine are unsuccessful.

- Bolus dose: 0.25 mg/kg (actual body weight) over 2 minutes (average dose: 20 mg); if rate control is insufficient after 15 minutes, a repeat bolus dose of 0.35 mg/kg over 2 minutes may be given (average dose: 25 mg). If bolus(es) do not terminate the arrhythmia, consider alternative therapy.

PEDIATRIC Always Reference BROSELOW Tape

Atrial tachyarrhythmias, rate control:

Very limited data available: Infants, Children, and Adolescents

IV:

- Initial bolus: 0.25 mg/kg over 5 minutes (maximum dose: 20 mg/dose [average adult dose]) followed by a continuous IV infusion. Dose should be individualized based on patient response.
- Continuous infusion (titrated to effect): 0.05 to 0.15 mg/kg/hour (Rate control achieved ≈10min)

DIPHENHYDRAMINE ♀B, Lactation Yes (Unsafe) Trade Name: **Benadryl**

Class / Mechanism of Action

Histamine H_1 Antagonist;
Competes with histamine for H1-receptor sites within the gastrointestinal tract, blood vessels, and respiratory tract; Also produces anticholinergic and sedative effects

Indications

Labeled Indications:
- Anaphylaxis and allergy disorders
- Motion Sickness
- Antitussive

Contraindications
- Hypersensitivity to diphenhydramine or any component of the formulation
- Acute Asthma
- Use on Neonates, premature infants, Nursing mothers

Adverse Reactions / Precautions
- Normally causes sedation, but may cause paradoxical excitation in children
- May have increased sedative effects when used with other sedatives or alcohol
- May cause hypotension (use with caution in patient with cardiovascular disease)
- Dry mouth

Dose and Administration:

ADULT

Anaphylaxis/Allergic Reactions and Motion Sickness:
Oral:
- **25-50mg** every 6-8 hours

IV Push:
- **50mg** once, prepare to administer epinephrine

Acute Hemolytic reaction (rapid onset of itching, chills, flushing, nausea/vomiting, coughing, wheezing, laryngeal edema, dyspnea, hypotension hemoglobinuria, rise in venous pressure, distended neck veins, crackles in lung bases):
IV:
- **50mg** once, after administration of epinephrine 0.5mL in lateral thigh

PEDIATRIC Always Reference BROSELOW Tape

Anaphylaxis/Allergic Reactions and Motion Sickness:
Oral, IM, IV:
- **1 mg/kg** every 6 hours

Max Doses:
2 to <6 years:
- **6.25mg** every 4-6hrs; max of 37.5mg/day

6 to <12 years:
- **12.5-25mg** every 4-6hrs; max of 150mg/day

≥12 years:
- See Adult dosing

DOBUTAMINE

♀B, **Lactation?** (Caution) Trade Name: **Dobutrex**

Class / Mechanism of Action

Adrenergic Agonist
Positive Inotropic agent. Stimulates beta1 adrenergic receptors: Increases HR and contraction force while sparing beta2 and alpha receptors. Onset IV: 1-2 minutes

Indications

Labeled Indications: Short term management of cardiac decompensation.

Contraindications

- Hypersensitivity to dobutamine or sulfites (some contain sodium metabisulfate), or any component of the formulation
- Idiopathic hypertrophic subaortic stenosis (IHSS)

Adverse Reactions / Precautions

- **Always attempt to correct Hypovolemia 1st when using vasopressors and/or inotropes**
  - **May be combined with Dopamine or Norepinephrine for hypotension not responding to fluid administration**
  - **No applicable use in hemorrhagic shock until fluid replacement therapy maximized!**
- Increase in BP is common, but does have a rare incidence of causing hypotension
- Increases HR
- May exaggerate ventricular ectopy

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Cardiac Decompensation:

IV:
Dobutamine may be combined with dopamine or norepinephrine for hypotension not responsive to fluid therapy.

- **2-20 mcg/kg/min**, start low and titrate to targeted MAP > 60 mmHg

- **Preparation:** Mix 250mg Dobutamine in 250mL D5W or NS for a concentration of 1000mcg/mL

Infusion Rates for Dobutamine at 1000mcg/mL

Desired Delivery Rate (mcg/kg/min)	Infusion Rate (mL/kg hour)
2.5	0.15
5	0.3
7.5	0.45
10	0.6
12.5	0.75
15	0.9
20	1.2

Cardiac Decompensation:

IV

- Refer to adult dose

DOPAMINE

♀C, **Lactation?** (Use Caution)

Trade Name: **Intropin**

Class / Mechanism of Action

Adrenergic Agonist; Vasopressor

Stimulates adrenergic and dopaminergic receptors. High doses stimulate dopaminergic and beta1 adrenergic receptors, producing cardiac stimulation and renal vasodilation. Very large doses stimulate alpha adrenergic receptors.

Indications

Labeled Indications:

Treatment of non-hemorrhagic shock (e.g. neurogenic, renal failure, cardiac decompensation) persisting after adequate fluid volume replacement

Unlabeled: Symptomatic bradycardia or heart block unresponsive to atropine or pacing

Contraindications

- Hypersensitivity to sulfites
- Ventricular Fibrillation

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Tachycardia and/or Arrhythmias: May increase HR and worsen arrhythmias
- Vesicant: Avoid extravasation, will cause tissue damage/necrosis
- Assure adequate circulatory volume to minimize need for vasoconstrictors. Monitor BP closely, avoid hypertension and adjust infusion rate as needed.

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Hemodynamic Support:

IV(Use microdrip chamber only):

- **5-20mcg/kg/min**; titrate to desired response. Infusion may be increased by 1-4mcg/kg/minute at 10 to 30 minute intervals until optimal response is obtained

Dopamine Dosage Efficacy:

- 1-5 mcg/kg/min= Dopaminergic effects: increased urine output, increased renal blood flow
- 5-10 mcg/kg/min= Beta1 effects: Increased CO, HR, and contractility
- >10 mcg/kg/min= Alpha1 effects: Increased BP, vasoconstriction

Note: Doses >20 mcg/kg/minute likely do not have a beneficial effect on blood pressure and may increase risk of tachyarrhythmias
Add additional vasopressor if Dopamine doses of 20 mcg/kg/min are inadequate. (**phenylephrine**, **norepinephrine**, **epinephrine**.

Hemodynamic Support:

IV:

- "Use adult dosing"

Note: Dopamine is a second line medication for hemodynamic support in Pediatric patients behind Epinephrine and Norepinephrine

Dopamine

EPINEPHRINE 1mg/mL (formerly 1:1000)

♀C, **Lactation?** (Caution)

Trade Name: **EpiPen / EpiPen Jr**

Class / Mechanism of Action

Alpha & Beta Agonist

Sympathomimetic, stimulates both alpha and beta adrenergic receptors, causing relaxation of the bronchial tree, cardiac stimulation (increasing myocardial oxygen consumption), and dilation of skeletal muscle blood vessels

Indications

- Allergic Reactions, Anaphylaxis
- Asthma (Bronchoconstriction)

Contraindications

- Not for IV use, must first dilute into 10mL NS syringe for Cardiac / IV use

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Chest Pain, Tachycardia, Arrhythmias, Palpitations, Sudden death
- Anxiety, Cerebral Hemorrhage, Headache
- Vesicant: Avoid extravasation, will cause tissue damage/necrosis
- Use with caution in patients taking tricyclic antidepressants; effects of epinephrine may be increased

Dose and Administration:

ADULT

Bronchodilator:

SubQ, IM: **1mg/mL**

- **0.3-0.5 mg** every 20 minutes for 3 doses

Nebulization:

- Add **0.5 mL** to nebulizer and dilute with 3 mL of NS; administer over 15 minutes

Anaphylaxis / Hypersensitivity reaction (ALS,2020):

IM: **1mg/mL**

- **0.3-0.5 mg** every 5-15 minutes until clinical improvement

IV Infusion:

- Initiate with an infusion at **5-15 mcg/minute** (with crystalloid) (See infusion chart next page)

Acute Hemolytic reaction

IM: **1mg/mL**

- **0.5mg** IM in lateral thigh
  - Repeat every 5-15min for moderate bronchospasm or facial/laryngeal edema.
- Follow with Diphenhydramine 50mg IV Push

PEDIATRIC Always Reference BROSELOW Tape

Bronchodilator:

SubQ: Infants and Children **1mg/mL**

- **0.01 mg/kg** (0.01 mL/kg) (maximum single dose: 0.5 mg) every 20 minutes for 3 doses

Nebulization:

- Children <4 years: Croup: **0.05 mL/kg** (maximum dose: 0.5 mL); dilute in 3 mL of NS. Administer over 15 minutes; do not administer more frequently than every 2 hours
- Children ≥4 years: Adult dosing

Anaphylaxis / Hypersensitivity reaction (PALS,2020): Infants and Children

IM:

- **0.01 mg/kg** (0.01 mL/kg of **1mg/mL** solution) (maximum single dose: 0.3 mg) every 5-15 minutes

EpiPen Jr, Children <15kg:

- **0.15 mg**; if anaphylactic symptoms persist, dose may be repeated in 5-15 minutes using an additional EpiPen Jr

EpiPen, Children ≥15 kg:

- **0.3 mg**; if anaphylactic symptoms persist, dose may be repeated in 5-15 minutes using an additional EpiPen

Epinephrine 1mg/1ml (1:1,000)					
Anaphylaxis					
Dosing Range: 5-15mcg/min (150-450mcg/hr)

EPINEPHRINE

♀C, **Lactation?** (Caution)

Trade Name: **Adrenalin**

1mg/10mL (formerly 1:10,000)

Class / Mechanism of Action

Alpha & Beta Agonist

Sympathomimetic, stimulates both alpha and beta adrenergic receptors, causing relaxation of the bronchial tree, cardiac stimulation, and dilation of skeletal muscle blood vessels

Indications

- Cardiac Arrest (VF, pulseless VT, asystole, PEA)
- Drip-Dose: Bradycardia (Symptomatic), Fluid Resistant Shock
- Push-Dose: Bradycardia, Hypotension, Refractory Anaphylaxis

Contraindications

- Uncontrolled hypertension is a relative contraindication, otherwise none

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Chest Pain, Tachycardia, Arrhythmias, Palpitations, Sudden death
- Anxiety, Cerebral Hemorrhage, Headache
- Vesicant: Avoid extravasation, will cause tissue damage/necrosis
- Use with caution in patients taking tricyclic antidepressants; effects of epinephrine may be increased

Dose and Administration:

ADULT

Asystole/pulseless arrest, pulseless VT/VF:

IV: **1mg/10mL** (0.1mg/mL) Pre-filled 10cc Syringe

- **1 mg** (10cc of 0.1mg/mL) every 3-5 minutes to ROSC, Follow each with 20mL flush

Drip-Dose: Bradycardia (Symptomatic), Fluid Resistant Shock:

IV Continuous Infusion:

- **2-20 mcg/minute** titrate to desired effect (HR >60, MAP >65)

Push-Dose: Bradycardia, Hypotension, Refractory Anaphylaxis:

IV/IO: Mix 100mcg (1mL of 1mg/10mL) Epinephrine in 10cc NS for concentration of 10mcg/mL

- **5-20mcg IV/IO push q 2-5min, titrate to desired response**

PEDIATRIC Always Reference BROSELOW Tape

Asystole, PEA, pulseless VT/VF, Unresponsive and Symptomatic Bradycardia in Infants

IV: **1mg/10mL –** 0.1mg/mL Pre-filled 10cc Syringe

- **0.01 mg/kg** (0.1 mL/kg of **1mg/10mL** [0.1 mg/mL]) (maximum single dose: 1 mg) every 3-5 minutes as needed or until ROSC

Severe Hypotension/shock and fluid resistant (unlabeled use):

IV: Continuous Infusion

- **0.1 - 1 mcg/kg/minute** titrated to desired effect

Epinephrine 1mg/10ml (1:10,000)					
Pressor for Hypotension

Macro-Drip (10gtt/ml) is set of choice for this infusion					
Start at lowest dose and titrate to desired effect					

Ertapenem	♀C, **Lactation Yes**	Trade Name: **Invanz**

Class / Mechanism of Action

Antibiotic (Carbapenem),
Biacteriocidal – broad spectrum, Inhibits bacterial cell wall synthesis by binding to one or more of penicillin-binding proteins which inhibits cell wall biosynthesis, causing bacteria to eventually lyse.

Labeled Indications: Used for infection control prophylaxis for traumatic open injuries and surgical prophylaxis.

Contraindications

- Hypersensitivity to cefazolin, other cephalosporin antibiotics, other beta-lactams, or any component of the formulation

Adverse Reactions / Precautions

- Superinfection – prolonged use may result in fungal or bacterial superinfection (including C.Difficile)

Dose and Administration: ADULT	**PEDIATRIC**

Infection Control:
Give 1g in 250 mL NS IV over 5 min, provides 24 hours of coverage.
 	
IV:
Adults:
• 1 g IV every 24 hrs
  ○ Max daily dose: 12 g/day
	Infection Control: Children <12 years & ≥12 years
	
	IV:
	Pediatrics:
	• <12years old: 15 mg/kg IV every 12 hrs
	  ○ Max daily dose: 100 mg/kg/day
	
	• ≥12 years old: 20 mg/kg IV or IM once daily
	  ○ Max daily dose: 1 g/day

ETOMIDATE

♀C, **Lactation?** (Caution)

Trade Name: **Amidate**

Class / Mechanism of Action

General Anesthetic

Very short acting non-barbiturate sedative/hypnotic used for induction of anesthesia with little cardiovascular effects. Onset of action: 30-60 seconds, Duration 5-10 minutes

Indications

Labeled Indications:

- Rapid Sequence Induction

Contraindications

- Hypersensitivity to etomidate or any component of the formulation

Adverse Reactions / Precautions

- **NO Analgesic properties!**
- Safety in children less than 10 years has not been established
- Inhibits adrenal steroid production; may increase mortality if repeat dosing is required

Dose and Administration:

ADULT	PEDIATRIC Always Reference BROSELOW Tape
RSI: IV: • **0.3 mg/kg** over 30-60 seconds for induction of anesthesia; **Note:** Limit to single dose for anesthesia/induction. Repeat dosing and continuous infusion (maintenance dosing) may increase patient mortality due to adrenal suppression and inability to respond to stress.	**RSI:** IV: Children <10 • Despite dosing on Broselow tape, not the preferred induction agent for this group due to limited safety information Children >10: • **0.3 mg/kg** over 30-60 seconds will produce rapid sedation lasting 10-15 minutes. ○ Max dose: 20 mg **Note:** Limit to single dose for anesthesia/induction. Repeat dosing and continuous infusion (maintenance dosing) may increase patient mortality due to adrenal suppression and inability to respond to stress.

FENTANYL

♀C, **Lactation Yes** (Not recommended) Trade Name: **Sublimaze**

Class / Mechanism of Action

Opioid Analgesic; General Anesthetic

Binds to opioid receptors within the CNS increasing pain threshold and altering pain reception; inhibits ascending pain pathways (blocking painful stimulus); produces CNS depression

Onset: IV almost immediate, Duration: IV 0.5-1 hour

Indications

Labeled Indications:

- Pain relief
- Adjunct to general or regional anesthesia

Contraindications

- Hypersensitivity to fentanyl or any component of the formulation

Adverse Reactions / Precautions

- When using only as pain med and not adjunct to general anesthesia, ensure Slow IV Push (3-5 min). Rapid infusion may result in chest wall rigidity, impaired ventilation, or respiratory distress/arrest Always be prepared for use of paralytic and intubation (positive control of airway).
- **Head trauma: Use with extreme caution in head injury, or suspected increased ICP; exaggerated increase in ICP may occur if patient management is inadequate.**
- May worsen Bradycardia
- May cause life-threatening hypoventilation and Reparatory depression
- CNS depression: Impairs physical and mental abilities

Dose and Administration:

ADULT

Pain Management:

IV: Slow (Unlabeled)

- **0.5-1mcg/kg** PRN for breakout pain q 30-60 min

IN:

- **100 mcg**

Note: Patients with prior opioid exposure may have increased tolerance and require higher dosing

Sedation during mechanical ventilation:

IV:

- Initial Bolus: **1-2mcg/kg**

Continued Sedation:

- **0.5-1mcg/kg/hr** infusion (See Infusion chart next page)

(Combine with 0.05-0.1mg/kg Midazolam for best effect)

- **0.5-2mcg/kg** IVP q 30-60min

Pretreatment for RSI:

3-5 min prior to RSI in pt's with Head injuries, Increased ICP, Cardiac Ischemia or Aortic Dissection (if situation allows):

- **3mcg/kg** slow IV push

Non-Traumatic Chest Pain (Cardiac)

- **25-50mcg** IV

PEDIATRIC Always Reference BROSELOW Tape

Pain Management:

IV: Slow (Unlabeled)

- **0.5-1mcg/kg** PRN for breakout pain q 30-60 min

Sedation during mechanical ventilation:

IV:

- Initial Bolus: **1-2mcg/kg**
- Continued Sedation: **0.5-2mcg/kg** q 30-60min or **0.5-2mcg/kg/hr** infusion

(Combine with 0.05-0.1mg/kg Midazolam for best effect)

Note: Titrate doses and intervals to pain relief/prevention. Monitor vital signs.

- Single IV doses last 0.5-1 hour

FUROSEMIDE

♀C, **Lactation Yes** (Caution)

Trade Name: **Lasix**

Class / Mechanism of Action

Antihypertensive; Loop Diuretic

Inhibits reabsorption of sodium and chloride in the kidney, causing increased loss of water, sodium, chloride, magnesium, and calcium within urine. When given IV it also causes rapid venous dilation. Symptomatic improvement of acute pulmonary edema approximately 15-20 minutes

Indications

Labeled Indications: Management of edema associated with heart failure and hepatic or renal disease;

- Management of edema associated with heart failure and hepatic or renal disease; acute pulmonary edema
- Hypertension (alone or in combination with other antihypertensives)

Contraindications

- Hypersensitivity to furosemide or any component of the formulation
- Anuria **(No pre-hospital utility in hypovolemic shock)**

Adverse Reactions / Precautions

- Can cause profound diuresis with resulting shock and electrolyte depletion. Monitor closely
  - May cause: Hypovolemia, Hypotension, hyponatremia, hypokalemia
- May potentiate effect of additional antihypertensives

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Acute pulmonary edema:

IV

- **40 mg** over 1-2 minutes. If response not adequate within 1 hour, may increase dose to 80 mg

Edema, heart failure:

IV, IM:

- Initial: **20-40 mg/dose**; if response is not adequate, may repeat the same dose or increase dose in increments of 20 mg/dose and administer 1-2 hours after previous dose (maximum dose: 200 mg/dose).

Continuous IV Infusion:

- Initial: IV bolus dose **20-40 mg** over 1-2 minutes, followed by continuous IV infusion doses of **10-40 mg/hour**. If urine output is <1 mL/kg/hour, double as necessary to a maximum of 80-160 mg/hour.

Edema, heart failure: Infants and Children

IV, IM:

- Initial: **1 mg/kg/dose**; if response not adequate, may increase dose in increments of 1 mg/kg/dose and administer not sooner than 2 hours after previous dose, until a satisfactory response is achieved; may administer maintenance dose at intervals of every 6-12 hours; maximum dose: 6 mg/kg/dose

GLUCAGON ♀B, Lactation? (Caution)

Class / Mechanism of Action

Antidote, Hypoglycemia Antidote, Diagnostic agent
Raises blood glucose levels by stimulating increased production of cyclic AMP, promoting hepatic glycogenolysis and gluconeogenesis

Indications

Labeled Indications: Management of hypoglycemia (Glucose <70 in adults or <60 in children)
Unlabeled:

- Beta-blocker or calcium channel blocker induced myocardial depression (with or without hypotension) unresponsive to standard measures
- Hypoglycemia secondary to insulin or sulfonylurea overdose (as adjunct to dextrose)

Contraindications

- Hypersensitivity to glucagon or any component of the formulation
- Insulinoma / Pheochromocytoma

Adverse Reactions / Precautions

- Should NOT be used as 1st line medication for hypoglycemia or Altered mental status
  - **Hypoglycemia patients should receive dextrose**. If IV access cannot be established or if dextrose is not available, glucagon may be used as alternate until dextrose can be given.
- Thiamine should precede use in patient with suspected alcoholism or malnutrition

Dose and Administration: **ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
Hypoglycemia: IV, IM, SubQ: • **1 mg**; may repeat in 20 minutes as needed **Beta-blocker / Calcium channel blocker overdose (myocardial depression)** unresponsive to standard measures (unlabeled use): IV: **(ACLS, 2015)** • **3-10 mg** (or 0.05-0.15 mg/kg) bolus followed by an infusion of 3-5 mg/hour (or 0.05-0.1 mg/kg/hour); titrate infusion rate to achieve adequate hemodynamic response	***Hypoglycemia:** IV, IM, SubQ: • **Children <20 kg: 0.5 mg** or 20-30 mcg/kg/dose; repeated in 20 prn. • Children ≥20 kg: Adult dosing. **Note:** IV dextrose should be given ASAP; if patient fails to respond to glucagon, IV dextrose must be given ***Only use if hyperinsulinemia thought to be cause of hypoglycemia (rare in kids). If hypoglycemic without glycogen stores, Glucagon will be ineffective.** **Beta-blocker / Calcium channel blocker overdose (myocardial depression)** unresponsive to standard measures (unlabeled use): IV: • **30-150mcg/kg** bolus. Can be repeated if no response in 15 min. Follow with an infusion of 20-70mcg/kg/hr; titrate infusion rate to achieve adequate hemodynamic response

HEPARIN

♀C, Lactation No

Trade Name:

Class / Mechanism of Action

Anticoagulant

Inactivates thrombin and activated coagulation factors (IX, X, XI, XII, and plasmin) and prevents conversion of fibrinogen to fibrin.

Indications

Labeled Indications: Treatment of thromboembolic disorders

Unlabeled: ST elevation MI (STEMI) as an adjunct to thrombolysis; unstable angina/non-STEMI

Contraindications

- Hypersensitivity to heparin or any component of the formulation
- Active Bleeding (Trauma Patient)

Adverse Reactions / Precautions

- Continuously monitor for bleeding: Stop immediately if any bleeding occurs
- Urticarial reactions and anaphylaxis can occur

Dose and Administration:

ADULT

Acute coronary syndromes: STEMI/Unstable Angina as an adjunct to fibrinolysis (full-dose alteplase**:**

IV:

- Initial bolus of **60 units/kg** (MAX: 4000 units)
  - Maintenance: 12 units/kg/hour (MAX: 1000 units/hour) as continuous infusion.

Treatment of venous thromboembolism:

IV: (unlabeled dosing)

- DVT/PE: **80 units/kg** (or alternatively 5000 units) IV push followed by continuous infusion of 18 units/kg/hour

Note: Heparin is ONLY for use only under written direction of referring provider or direct consultation with medical director.

PEDIATRIC Always Reference BROSELOW Tape

Treatment of venous thromboembolism:

IV: (unlabeled dosing)

>1 year

- DVT/PE: **75 units/kg** IV push followed by continuous infusion of 20 units/kg/hour

HETASTARCH

♀C, **Lactation Yes** (Caution)

Trade Name: **Hextend**

Class / Mechanism of Action

Plasma Volume Expander, Colloid

Colloidal starch producing plasma volume expansion. Onset of Action: approximately 30 minutes

Indications

Labeled Indications: Volume expander used in treatment of hypovolemic / hemorrhagic shock

Contraindications

- Hypersensitivity to hydroxyethyl starch or any component of the formulation
- Renal failure with oliguria and anuria (not related to Hypovolemia)
- Fluid overload conditions, (pulmonary edema, congestive heart failure
- Pre-existing bleeding or coagulation disorders (eg, von Willebrand's disease): Use caution in bleeding disorders; may increase risk of more bleeding

Adverse Reactions / Precautions

- Anaphylactoid reactions (allergies to corn)

Dose and Administration:	**ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
Plasma volume expansion: IV • **250-500ml** Bolus. May repeat PRN (up to 1500 mL/day). Titrate to individual hemodynamic needs (Sys BP >90). **Notes:** • May be administered via infusion pump or pressure infusion. • Do not administer with blood through the same line / tubing • Change tubing or flush extensively with NS before administering blood through the same line.		

HYDROMORPHONE ♀C, Lactation Yes(Not Recommended) Trade Name: **Dilaudid**

Class / Mechanism of Action

Opioid Analgesic

Binds to opioid receptors within the CNS increasing pain threshold and altering pain reception; inhibits ascending pain pathways (blocking painful stimulus); produces CNS depression

Onset: IV 10-20 minutes. Duration 2-4 hours

Indications

Labeled Indications: Moderate to severe pain.

Contraindications

- Hypersensitivity to hydromorphone or any component of the formulation
- Severe respiratory depression (in absence of resuscitative equipment or ventilator support)
- Acute or severe asthma
- Paralytic ileus

Adverse Reactions / Precautions

- Always be prepared for use of paralytic and intubation (maintain positive control of airway).
- **Head trauma: Use with extreme caution in head injury, or suspected increased ICP; exaggerated increase in ICP may occur.**
- May cause Hypotension, Use with caution in hypovolemic patients.
- May cause life-threatening Reparatory depression
- CNS depression: Impairs physical and mental abilities

Dose and Administration: **ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
Acute pain (moderate-to-severe): IV: (Slow) • **0.5mg (range 0.25-2mg) IV/IO q 1-6hr as prn** • **Critically ill require lower dose, opioid tolerant may require higher dose** • Continuous infusion: Usual dosage range: **0.5-3 mg/hour (See infusion chart next page)**	**Acute pain (moderate-to-severe):** IV: (Slow) • Children: **0.015mg/kg** IV q 4-6 PRN • Adolescents >50kg: Refer to adult dosing

HYDROMORPHONE (DILAUDID)					
Dosing Range: 0.5-3mg/hr (8.3-50mcg/min)					
MIX 2 mg/100 mL CONCENTRATION 20 mcg/mL

3	150	150	50	38	25
Macro-Drip (20gtt/ml) or Micro-Drip is set of choice for this infusion					
Start at lowest dose and increase rate by 0.5mg/hr PRN for appropriate pain management					

HYDROXOCOBALAMIN ♀C, Lactation? (Caution) Trade Name: **Cyanokit®**

Class / Mechanism of Action

Antidote; Vitamin

Precursor to Vitamin B_{12} (cyanocobalamin). Binds cyanide ion to form cyanocobalamin which is excreted within urine

Indications

Labeled Indications:

- IM: Treatment of pernicious anemia and B12 deficiencies
- IV: (Cyanokit®) Treatment of known or suspected cyanide poisoning

Contraindications

- No contraindications when treating for suspected or known cyanide poisoning

Adverse Reactions / Precautions

- May cause transient hypertension (≥180mmHG systolic, ≥110mmHG diastolic)
- Will cause red colored urine and skin

Dose and Administration:

ADULT

Cyanide Poisonings:

IV (**Note:** If cyanide poisoning is suspected, antidotal therapy must be given immediately)

- Initial: **5 grams** as single infusion given over 15 min
  - Repeat a second 5 gram dose based on severity and clinical response.
  - Maximum cumulative dose: 10 grams

Smoke Inhalation / Fire victims: (Closed space exposure with evidence of airway injury: soot in mouth / nose / sputum)

- May present with both cyanide and carbon monoxide poisoning. Hydroxocobalamin is the agent of choice for treating cyanide toxicity in this setting.

Preparation:

Cyanokit®: Reconstitute each vial with 200 mL of NS (LR and D5W also OK).

- Do not shake vial (gently mix)
- Do not use if solution is not dark red

PEDIATRIC Always Reference BROSELOW Tape

Cyanide Poisonings:

IV: (Unlabeled Use)

- Initial: **70mg/kg (max 5 grams)** as single infusion given over 15 min
  - Repeat a second dose of 35mg/kg based on severity and clinical response.

Smoke Inhalation / Fire victims: (Closed space exposure with evidence of airway injury: soot in mouth / nose / sputum)

- May present with both cyanide and carbon monoxide poisoning. Hydroxocobalamin is the agent of choice for treating cyanide toxicity in this setting.

KETAMINE

♀C, Lactation Yes (Risk not ruled out) Trade Name: **Ketalar**

Class / Mechanism of Action

General Anesthetic

Dissociative anesthetic; produces a cataleptic like state acting directly on the cortex and limbic system. Onset of action IV: 30-60 seconds; Duration is dose dependent averaging 10-20 minutes

Indications

Labeled Indications: Induction and maintenance of general anesthesia
Unlabeled: Analgesia and sedation

Contraindications

- Hypersensitivity to ketamine or any component of the formulation
- Conditions that cannot tolerate increases in blood pressure
  - E.g. spontaneous cerebral hemorrhage or acute coronary syndrome hypertension
- Children <3 mo age

Adverse Reactions / Precautions

- Rapid IV administration may cause hypotension, apnea, or laryngospasm. Large doses may cause hypotension and respiratory depression
- Use with caution in patients with cardiovascular disease. Continuously monitor cardiac function.
- **Preferred general anesthetic / sedative for hypo/normotensive head injury patient.**
- **Dosing between 0.5-0.9 mg/kg IV (and equivalent IM dose) can give patients the feeling of unreality leading to agitation and should be avoided.**

Dose and Administration:

ADULT

LOW DOSE:

Analgesia:

IV/IO Push (over 1 min)
- **0.1 - 0.2 mg/kg,** repeat q 10-30 prn

IM/IN
- **0.5 mg/kg,** repeat q 10-30 prn

HIGH DOSE:

RSI / Induction of anesthesia; Combative Patients:

IV Push
- **1-2 mg/kg**

IM
- **4-5 mg/kg**

Maintenance of anesthesia:

IV :
- **0.5-2 mg/kg** dose every 10-20 minutes

IV Continuous Infusion
- **0.5-2mg/kg bolus then 0.5-1 mg/kg/hr**. Titrate levels by 0.25mg/kg/hr PRN to achieve appropriate sedation. **(See infusion chart next page)**

PEDIATRIC Always Reference BROSELOW Tape

Analgesia:

IM:
- **0.5 mg/kg,** repeat q 10-30 prn

IV:
- **0.1 – 0.2 mg/kg,** repeat q 10-30 prn

Induction of anesthesia (unlabeled dosing):

IV:
- **1-2 mg/kg (3-5mg/kg for procedural sedation)**

Maintenance of anesthesia:

IV :
- **½ to Full induction dose** every 20-30 minutes

IV Continuous Infusion:
- **0.5-1 mg/kg/hr**. Titrate levels by 0.25mg/kg/hr PRN to achieve appropriate sedation.

NOTE Avoid sub-dissociative doses to prevent emergence phenomenon.

NOTE: *If patient experiences Ketamine Induced Agitation (Emergence Phenomena) give Midazolam 2-5mg IV x1 for adults and 0.05 mg/kg for children not hypotensive or in danger of being* hypotensive.

KETAMINE (KETALAR)						
Dosing Range: 1-3mg/kg/hr (17-50mcg/kg/min)

KETOROLAC

♀C, **Lactation Yes**(Caution)

Trade Name: **Toradol**

Class / Mechanism of Action

Nonsteroidal Anti-inflammatory Drug (NSAID)

Inhibits cyclooxygenase (COX 1 & 2) enzymes, which decreases production of prostaglandin precursors. Provides antipyretic, analgesic, and anti-inflammatory action.

Indications

Labeled Indications: Short term management of moderate to severe acute pain as an opioid alternative.

Contraindications

- Hypersensitivity to ketorolac, aspirin, other NSAIDs, or any component of the formulation.
- High risk of bleeding, recent history of GI bleeding or perforation, known history of peptic ulcer disease.
  - **Not for use as pain management for battlefield trauma patient!**
- Suspected cerebrovascular bleeding Dizziness, Flushing, Diaphoresis, Tremor, Weakness
- Risk of renal failure secondary to volume depletion
- Concurrent use with other NSAIDs

Adverse Reactions / Precautions

- Inhibits platelet function
- Associated with an increased risk of adverse cardiovascular thrombotic events, including MI and stroke
- May increase risk of GI irritation, inflammation, ulceration, bleeding, and perforation.
- May cause severe bronchospasm in patients with asthma
- May cause new onset hypertension or worsening of existing hypertension.

Dose and Administration:

ADULT

Pain management (acute; moderately severe):

Patients ≥50 kg

IM:

- **15-30 mg** every 6 hours (maximum daily dose: 120 mg)

IV:

- **15 mg** every 6 hours (maximum daily dose: 120 mg)

Adults ≥65 years and/or adults ≤50 kg

IM:

- **15-30 mg** every 6 hours (maximum daily dose: 60 mg)

IV:

- **15 mg** every 6 hours (maximum daily dose: 60 mg)

PEDIATRIC Always Reference BROSELOW Tape

Pain management (acute; moderately severe):

Adolescents >17 years only:

- Refer to adult dose

LABETALOL

♀C, **Lactation Yes** (Caution)

Trade Name: **Trandate**

Class / Mechanism of Action

Beta Blocker with alpha blocking activity

Blocks alpha and beta1/beta2 adrenergic receptor sites. Onset IV: 2-5 minutes

Indications

Labeled Indications: Treatment of hypertension.

- IV: Treatment of severe hypertension and hypertensive emergencies

Unlabeled:

- Pre-eclampsia and severe hypertension in pregnancy, hypertension during acute ischemic stroke, and Pediatric hypertension

Contraindications

- Hypersensitivity to labetalol or any component of the formulation
- **Bradycardia <60bpm, heart block >1st degree**
- Uncompensated heart failure, Cardiogenic shock
- Asthma

Adverse Reactions / Precautions

- Symptomatic hypotension with or without syncope, Monitor EKG closely
- Use with extreme caution in patients with compensated heart failure and Bradycardia
- Patient with bronchospastic diseases (reactive airway) should not use Beta blockers

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Acute Hypertension (hypertensive emergency/urgency:

Hypertensive Crisis
(Sys: >185/Dia: >110)

- **10-20 mg** IV over 1-2 minutes. May repeat one time

Continuous Infusion:

If continued medication required, **2-8mg/min**

Note: Goal to lower MAP by no more than 25% within minutes to one hour.

***Hypertension emergencies:**

IV Continuous Infusion

- 0.4-1 mg/kg/hour with a maximum of 3 mg/kg/hour have been used; administration requires the use of an infusion pump.
- Intermittent bolus doses of 0.3-1 mg/kg/dose have been reported

*Not 1st Line medication for children

Pearls:

For inter-facility transports with confirmed Ischemic CVA, Intraparenchymal Hemorrhagic CVA, or Spontaneous Non-traumatic SAH manage Hypertension according to diagnosis or guidance from sending facility

- Ischemic CVA Lytic ineligible: SBP < 220 and DBP <120
- Ischemic CVA Lytic eligible: SBP <185 and DBP <110
- Intraparenchymal Hemorrhagic CVA: SBP <180
- Non-traumatic SAH: SBP <160

LEVETIRACETAM ♀C, Lactation Yes (Caution) Trade Name: **KEPPRA**

Class / Mechanism of Action

Anticonvulsant

Causes modulation of synaptic neurotransmitter release through binding to the synaptic vesicle protein SV2A in the brain.

Indications

Labeled Indications

- Treatment of focal (partial) onset seizures

Unlabeled:

- Traumatic brain injury, severe acute (short-term seizure prophylaxis); Status epilepticus; Craniotomy, seizure prophylaxis; Subarachnoid hemorrhage (short-term seizure prophylaxis)

Contraindications

- Hypersensitivity to any component of the formulation

Adverse Reactions / Precautions

- May cause CNS depression
- Dermatologic reactions, possibly severe (TEN, SJS, etc)
- Hypertension has been reported in children <4 years
- Hematologic effects: Decreases in red blood cell counts, hemoglobin, hematocrit, white blood cell counts, and neutrophils and increases in eosinophils have been observed

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Traumatic brain injury (severe acute) (short-term seizure prophylaxis):

- Loading dose: 20 mg/kg (rounded to the nearest 250 mg) over 60 minutes
- Maintenance dose: 1,000 mg over 15 minutes every 12 hours for 7 days

Status epilepticus:

- IV: 1,000 to 3,000 mg administered at a rate of 2 to 5 mg/kg/minute **or** 40 to 60 mg/kg as a single dose infused over 15 minutes in combination with a parenteral benzodiazepine. Maximum dose: 4,500 mg.

Status epilepticus, refractory: (Limited data available)

Infants, Children, and Adolescents:

- IV: 20 to 60 mg/kg over 15 minutes as a single dose

LIDOCAINE

♀B, **Lactation Yes** (Caution) Trade Name: **Xylocaine (Cardiac)**

Class / Mechanism of Action

Antiarrhythmic
Suppresses automaticity of cardiac conduction tissue.

Indications

Labeled Indications: Acute treatment of ventricular arrhythmias from myocardial infarction (alternate to amiodarone when amiodarone not available)

Unlabeled: (ACLS, 2015)

- Hemodynamically stable monomorphic VT and polymorphic VT
- Pulseless VT / VF (unresponsive to defibrillation, CPR, and vasopressor administration)
- Monomorphic VT secondary to drug, when amiodarone is not available

Contraindications

- Hypersensitivity to lidocaine or any component of the formulation
- Prophylactic use in AMI
- Bradycardia, severe degrees of SA, AV, or intraventricular heart block
- Wolff-Parkinson-White syndrome, Adam-Stokes syndrome

Adverse Reactions / Precautions

- Continuous EKG monitoring is necessary
- Increased ventricular rate may be seen when given to a patient in AFib
- At high doses, monitor closely for CNS toxicity, seizure, depression, and respiratory depression.
  - D/C immediately if toxicity develops
- The elderly may have increased chance of CNS and cardiovascular side effects.

Dose and Administration: ADULT

Cardiac Arrest from VF/VT, (if Amiodarone is not available): (ACLS, 2015)**:**

IV, IO:

- Initial dose: **1 to 1.5mg/kg**
- For refractory VF may give additional **0.5 to 0.75mg/kg** IV push, repeat in 5 to 10 minutes
  - Maximum of 3 doses or total of 3mg/kg

Perfusing Arrhythmia (if amiodarone is not available): Stable VT, wide complex tachycardia, significant ectopy:

IV, IO

- Doses ranging from **0.5 to 0.75mg/kg and up to 1 to 1.5mg/kg.** Repeat 0.5 to 0.75mg/kg every 5 to 10 minutes
  - Maximum cumulative dose 3mg/kg

Flush after initiation of IO:

- May add 2-3 ml Lidocaine 2% (without epinephrine) to 5ml NS flush

Local Anesthesia during Tube/Finger Thoracostomy

- Draw 10ml 2% Lidocaine and locally anesthetize incision area.

Decompression Illness/ Arterial Gas Embolism:

- **1.5mg/kg** IV/IO

Dose and Administration: PEDIATRIC Always Reference BROSELOW Tape

VF/Pulseless VT, Wide Complex Tachycardia (with pulses): (PALS, 2015)

IV, IO:

- Initial dose**: 1mg/kg**

2015 AHA ACLS guidelines state:
"There is inadequate evidence to support the routine use of lidocaine after cardiac arrest. However, the initiation or continuation of lidocaine may be considered immediately after ROSC from cardiac arrest due to VF/pVT"

Maintenance Infusion (Adults and Peds):
IV, IO: Continuous Infusion

- **1-3 mg/hour** (or 20-50 mcg/kg/minute).

LORAZEPAM

♀D, **Lactation Yes** (not recommended) Trade Name: **Ativan**

Class / Mechanism of Action

Benzodiazepine
Acts as an Anxiolytic/Hypnotic, anticonvulsant and sedative.
Onset of action: IV Sedation 2-3 minutes; IM hypnotic, 15-30 minutes. Duration: IV, 8-12 hours.

Indications

Labeled Indications: Anesthesia premedication, Status epilepticus
Unlabeled:

- Rapid tranquilization of the combative / agitated patient
- Alcohol withdrawal delirium / syndrome
- Seizures
- Induce Sedation and Amnesia (Midazolam is primary medication)

Contraindications

- Hypersensitivity to Lorazepam or any component of the formulation or other benzodiazepines
- Acute narrow angle glaucoma, Acute Alcohol Intoxication, Sleep apnea
- Respiratory Insufficiency/Depression (except during mechanical ventilation)
  - Overdose Reversal: FLUMAZENIL **can be used, however it carries elevated risk. Respiratory support until the medication is metabolized is traditionally the best care in Benzodiazepine overdose**
- Neurologic Depression (Head Trauma) (unless having active seizure)

Adverse Reactions / Precautions

- **No Analgesic properties** (Narcotic pain control is needed for RSI'd / Intubated trauma patients)
- May Cause Respiratory depression: Do not give without stable IV line and BVM (airway control) ready
- Hypotension, vasodilation
- Amnesia, confusion, drowsiness, slurred speech (Paradoxical Reactions possible: aggressiveness, agitation, anxiety, inappropriate behavior)

Dose and Administration:

ADULT

Acute Seizures:
IV:

- **2-4mg** slow IV push, may repeat x2 every 3-5 minutes as needed.

Note: Not recommended IM for seizure due to erratic absorption.

Anxiety:

IV:

- 0.5-2mg slow IV push

Rapid tranquilization of agitated / combative patient (Off-label use):
IV, IM:

- **2-4mg** every 30-60 minutes**;** may be used alone or administered with an antipsychotic (i.e. haloperidol)

PEDIATRIC Always Reference BROSELOW Tape

Acute Seizures / Status epilepticus (unlabeled use):
IV:

- **0.05-0.1 mg/kg;** repeat doses every 5 minutes (max x2) for clinical effect. Max 4mg

Agitation:

- **0.05 mg/kg/dose** q 20-30 min PRN

MAGNESIUM SULFATE ♀D, Lactation Yes(Caution)

Class / Mechanism of Action

Anticonvulsant, Electrolyte Supplement

IV magnesium decreases acetylcholine in motor nerve terminals and slows rate of SA node impulse formation and prolongs conduction time. Magnesium functions to facilitate the movement of calcium, sodium, and potassium in and out of cells.

Indications

Labeled Indications:

- Prevention and treatment of seizures in pregnancies with severe pre-eclampsia or eclampsia
- Torsades de Pointes: Cardiac arrhythmias (VT/VF) cause by low serum magnesium

Contraindications

- Hypersensitivity any component of the formulation
- Myocardial damage and heart blocks
- Use for pre-eclampsia / eclampsia during 2 hour period before delivery

Adverse Reactions / Precautions

- Possible cardiovascular arrest, respiratory depression, and hypotension in large doses
- Hypomagnesaemia is often joined by hypokalemia and requires correction in order to normalize potassium.

Dose and Administration:

ADULT

Torsades de pointes or VF/pulseless VT associated with torsades de pointes (unlabeled use):
IV, IO:

- **1-2 g** over 15 minutes

Wheezing in Respiratory Distress (3rd line drug):
IV:

- **2 Grams** over 20min

Seizure (Refractory to Benzodiazepines):
IV:

- **1-2 Grams** over 30 min

Eclampsia/pre-eclampsia, severe (unlabeled):
IV:

- **4-6 g** over 15-20 minutes followed by 2 g/hour continuous infusion

PEDIATRIC Always Reference BROSELOW Tape

Torsades de pointes:
IV, IO:

- **25-50 mg/kg/dose** over several minutes
  - maximum single dose: 2000 mg

Respiratory Distress:
IV:

- **25-75 mg/kg** over 30 min (max 2 grams)

Magnesium Sulfate should be diluted into 50-100ml NS or D5W for all Adult and Pediatric infusions

MANNITOL 20% ♀C, Lactation? (Caution)

Class / Mechanism of Action

Osmotic Diuretic

Increases osmotic pressure of glomerular filtrate. This reduces kidney reabsorption of water and electrolytes and increases urinary output. Decreases cerebral blood volume and intracranial pressure (ICP) while increasing cerebral blood flow and O2 transport. Onset of action is 15-30 minutes

Indications

Labeled Indications:

- Reduction of increased ICP secondary to cerebral edema
- Reduction of elevated intraocular pressure
- Urinary excretion of toxic substances

Contraindications

- Hypersensitivity to mannitol or any component of the formulation
- Active intracranial bleeding
- Pulmonary congestion and edema
- Severe renal disease, or renal dysfunction after mannitol use
- Severe dehydration: (Do NOT use in **under-resuscitated or hypotensive casualties**)

Adverse Reactions / Precautions

- Chest pain, CHF, tachycardia, circulatory overload (with rapid administration), peripheral edema
- Headache, seizure
- Fluid and electrolyte imbalance, dehydration and hypovolemia
- Keep in a temperature controlled climate. Will crystalize at low temperatures.

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Moderate to severe head injury, *Patient continuing to deteriorate or showing signs of herniation despite adjustment to ventilation and starting hypertonic saline.*

IV

- **1 g/kg** IV bolus over <20 minutes.
- Follow with **0.25 g/kg** IVP every 4 hours

Vital Functions Goal in Head Injury (Prevention of secondary brain injury)**:**

- Keep SBP >90mmHg, MAP >60mmHg, and SaO2 >93%. [(CPP = MAP – ICP) Minimal goal CPP >60mmHg]

Note: Always have urinary catheter in place and monitor output.

Increased intracranial pressure (unlabeled dosing):

IV:

- **0.25-1 g/kg/dose**;
- Maintenance dose of **0.25-0.5 g/kg** IV q 4-6hrs prn to maintain serum osmolality <300-320 mOsm/kg

METHYLPREDNISOLONE ♀C, Lactation Yes(Caution) Trade Name: **SoluMedrol**

Class / Mechanism of Action

Systemic Corticosteroid
Anti-inflammatory, Immunosuppressant, shock

Indications

Labeled Indications: Treatment of a variety of diseases: allergic, inflammatory, hematologic, neoplastic, and autoimmune;
Unlabeled:
None identified unless added by medical direction.

Contraindications

- Hypersensitivity to methylprednisolone or any component of the formulation
- No other in emergency setting

Adverse Reactions / Precautions

- Not for use in treatment of head injury; increased mortality has occurred in head injury patients treated with high dose IV methylprednisolone.
- No immediate effect will be observed while treating in the pre-hospital environment. Onset of action may take several hours

Dose and Administration: ADULT	**PEDIATRIC** Always Reference BROSELOW Tape
Asthma exacerbations, including status asthmaticus IV: • **125mg** x 1 dose **Allergic Reaction:** IV: • **125mg** x 1 dose **Note:** Only methylprednisolone sodium succinate can be used for IV doses.	**Asthma exacerbations, including status asthmaticus** IV: • Children <12 years: **1-2 mg/kg** initial dose**;** followed by **0.5-1 mg/kg** q 6 hrs**.** (maximum: 60 mg/day) **Allergic Reaction** IV • **2 mg/kg** x 1 dose **Note:** Only methylprednisolone sodium succinate can be used for IV doses.

METOCLOPRAMIDE ♀B	Trade Name: Reglan

Class / Mechanism of Action

Prokinetic Agent: Antiemetic, Upper GI Stimulant
Potent dopamine-receptor antagonist. At higher doses blocks serotonin receptor in chemoreceptor trigger zones of CNS. Increases GI tract motility and gastric emptying. Onset of action 1-5 minutes via IV with a duration of 1-2 hours.

Indications

Labeled Indications: Prevention of postoperative nausea and vomiting; Acid Reflux/Heartburn/GERD; Migraine Headache

Contraindications

- Hypersensitivity to glucagon or any component of the formulation
- Insulinoma / Pheochromocytoma

Adverse Reactions / Precautions

- Hypersensitivity, History of tardive dyskinesia or dystonic reaction to Metoclopramide in the past, GI Obstruction or Hemorrhage, and seizure disorder (epilepsy).

Dose and Administration: ADULT	PEDIATRIC Always Reference BROSELOW Tape
5-10 mg IV/IO slow push; repeat dose x1 every 20-30 minutes PRN for a max of 20mg. *Rapid IV push may cause intense feelings of anxiety and restlessness* Ideal administration to Prevent Agitation/Adverse Effects: Dilute in a 50 or 100ml NS bag and infuse over 10-15 minutes.	**Not recommended or approved for routine pediatric use**

METOPROLOL

♀C, **Lactation?**(Not Recommended) Trade Name: **Lopressor**

Class / Mechanism of Action

Beta-1 Selective Beta-Blocker; Antihypertensive; Antianginal Agent

Selective inhibitor of $beta_1$-adrenergic receptors; competitively blocks $beta_1$-receptors, with little or no effect on $beta_2$-receptors at oral doses <100 mg (in adults); does not exhibit any membrane stabilizing or intrinsic sympathomimetic activity.

Onset of action: IV: 5 minutes, Duration 3-5 hours

Indications

Labeled Indications: Angina, Hypertension, Myocardial infarction

Unlabeled: Atrial fibrillation/flutter; Hypertrophic cardiomyopathy; Marfan syndrome with aortic aneurysm; Migraine prophylaxis; Supraventricular tachycardia (AVNRT, AVRT, focal atrial tachycardia); Thyrotoxicosis; Ventricular arrhythmias

Contraindications

- Hypersensitivity to metoprolol, any component of the formulation, or other beta-blockers; second- or third-degree heart block
- Severe sinus bradycardia (heart rate <45 beats/minute); significant first-degree heart block (P-R interval ≥0.24 seconds); systolic blood pressure <100 mm Hg; moderate to severe cardiac failure

Adverse Reactions / Precautions

- Cardiovascular: Hypotension, bradycardia, first degree atrioventricular block, arterial insufficiency, cardiac failure, CVA, cold extremities, palpitations, peripheral edema, claudication
- Central nervous system: Dizziness, fatigue, depression, vertigo, confusion, disturbed sleep, hallucination, headache, insomnia, nightmares, temporary amnesia, tinnitus

Dose and Administration: ADULT

Atrial fibrillation or atrial flutter (off-label use):

Acute ventricular rate control:

IV:

- 2.5 to 5 mg over 2-5 minutes; repeat dose every 5 minutes as needed; maximum total dose: 15 mg.

Supraventricular tachycardia/Ventricular arrhythmias (off-label use):

Note: For hemodynamically stable patients if vagal maneuvers and/or adenosine are unsuccessful.

IV:

- 2.5 to 5 mg over 2-5 minutes; repeat dose every 5 minutes as needed to achieve a ventricular rate of 90 – 100; maximum total dose: 15 mg.

Note: For sustained ventricular tachycardia, Beta-blockers are generally administered in addition to an antiarrhythmic drug (eg, Amiodarone) for these indications. A beta-blocker is also used to reduce shocks in patients who receive an implantable cardioverter defibrillator for these indications; propranolol may be the preferred beta-blocker in these situations

PEDIATRIC Always Reference BROSELOW Tape

Note: Guidelines do not recommend beta-blockers as initial therapy in pediatric patients; beta-blockers should be reserved for use in patients who have contraindications to preferred agents or after ≥2 preferred agents have failed in patients with hypertension and chronic kidney disease, proteinuria, or diabetes mellitus.

MIDAZOLAM

♀**D, Lactation Yes**(Caution)

Trade Name: **Versed**

Class / Mechanism of Action

Benzodiazepine

Acts as an Anxiolytic/Hypnotic, anticonvulsant and sedative.

Onset of action: Sedation; IV: 1-5 minutes, IM: 15 minutes, Intranasal: 4-8 minutes

Duration: IV, less than 2 hours. (20-30 Minutes per ECCN Nurse Protocols, May 2012)

Indications

Labeled Indications: Preoperative sedation, induction and maintenance of general anesthesia

Unlabeled: Anxiety / agitation, status epilepticus, conscious sedation (intranasal)

Contraindications

- Hypersensitivity to midazolam or any component of the formulation or other benzodiazepines
- Acute narrow angle glaucoma, Acute Alcohol Intoxication
- Respiratory Insufficiency/Depression (except during mechanical ventilation)
- (Overdose Reversal: **FLUMAZENIL can be used, however it carries elevated risk. Respiratory support until the medication is metabolized is traditionally the best care in Benzodiazepine overdose)**
- Should not be used in shock
- Neurologic Depression (Head Trauma) (unless having active seizure)

Adverse Reactions / Precautions

- **No Analgesic properties** (Narcotic pain control is needed for RSI'd / Intubated trauma patients)
- May Cause Respiratory depression: Do not give without stable IV line and BVM (airway control) ready
- Hypotension, vasodilation
- Amnesia, confusion, drowsiness, slurred speech (Paradoxical Reactions possible: aggressiveness, agitation, anxiety, inappropriate behavior)

Dose and Administration: ADULT

Induction for RSI; Continued sedation; Hyperthermia:

IV:

- **Induction 0.1mg/kg** IV/IO
- **Continued Sedation .05 mg** IV/IO
- **Infusion sedation** 0.05 mg/kg bolus IV, then titrate 0.05-0.1mg/kg/hr IV gtt

Transcutaneous Pacing / Cardioversion, Anxiety, Agitation,:

IV

- **2.5-5mg** q 15-30 PRN

Seizure Dosage:

- If no IV/IO access, **5mg IN** (repeat in 10 minutes in opposite nostril if still seizing (preferred) or **10mg IM** (alternate)
- **5mg IV/IO**, may repeat

After 3 doses should consider addition of another agent.

PEDIATRIC Always Reference BROSELOW Tape

Procedural sedation; Transcutaneous Pacing; Cardioversion:

IV:

- **0.05-0.1mg/kg** q 15-30 PRN

Intranasal (unlabeled route):

- **0.2-0.5 mg/kg** (maximum total dose: 10 mg or 5 mg per nare

Induction/RSI (Not preferred drug)

IV:

- **0.1-0.3 mg/kg**

Seizure

IV, IM:

- **0.2 mg/kg Q 15-30 PRN**

Status epilepticus, prehospital treatment (unlabeled use):

IV:

- Infants: **1-2 mg**
- 13-40 kg**: 4 mg once**
- >40 kg: Refer to adult dosing

MORPHINE

♀C, **Lactation Yes**(Caution)

Trade Name:

Class / Mechanism of Action

Opioid Analgesic

Binds to opioid receptors within the CNS increasing pain threshold and altering pain reception; inhibits ascending pain pathways (blocking painful stimulus); produces CNS depression

Onset: IV variable but rapid, Duration variable, patient dependent.

Indications

Labeled Indications: Moderate to severe acute and chronic pain; pain of myocardial infarction; preanesthetic medication

Contraindications

- Hypersensitivity to morphine sulphate or any component of the formulation
- Severe respiratory depression
- Acute or severe asthma (in an unmonitored setting or without resuscitative equipment)
- Paralytic ileus

Adverse Reactions / Precautions

- Always be prepared for use of paralytic and intubation (maintain positive control of airway).
- **Head trauma: Use with extreme caution in head injury, or suspected increased ICP; exaggerated increase in ICP may occur. Some formulations are specifically contraindicated.**
- May cause Hypotension, Use with caution in hypovolemic patients.
- May worsen Bradycardia
- May cause life-threatening hypoventilation and Reparatory depression
- CNS depression: Impairs physical and mental abilities

Dose and Administration:

ADULT

Chest Pain/AMI:

IV/IO:

- **2-5 mg** q 5-15 min PRN

Acute pain (moderate-to-severe):

IM, SubQ: The use of IM/ SubQ injections is no longer recommended especially for repeated administration due to painful administration, variable absorption and lag time to peak effect.

IV/IO: (Slow)

- **5mg (0.1 mg/kg, range 2.5 – 10mg)** every 1-6 hours PRN

PEDIATRIC Always Reference BROSELOW Tape

Acute pain (moderate-to-severe):

IM, SubQ: The use of IM/ SubQ injections is no longer recommended especially for repeated administration due to painful administration, variable absorption and lag time to peak effect.

IV: (Slow)

- **0.1-0.2 mg/kg** q 2-4 hr PRN, not to exceed 10 mg per dose

Continuous infusion:

- **10-30 mcg/kg/hour**; titrate PRN for pain

MOXIFLOXACIN ♀C, Lactation Yes Trade Name Avelox

Class / Mechanism of Action

Antibiotic (Fluoroquinolone)
Bactericidal - DNA gyrase inhibitor and topoisomerase IV inhibitor – which is an essential enzyme that maintains the superhelical structure, replication, transcription, and repair of bacterial DNA.

Indications

Labeled Indications: Used for infection control prophylaxis for traumatic open injuries and surgical prophylaxis.

Contraindications

- Hypersensitivity to cefazolin, other cephalosporin antibiotics, other beta-lactams, or any component of the formulation
- May cause QT prolongation.
- Avoid use in known aortic aneurysm or dissection

Adverse Reactions / Precautions

- Superinfection – prolonged use may result in fungal or bacterial superinfection (including C.Difficile)

Dose and Administration: ADULT	PEDIATRIC

Infection Control:
For PO tolerable patients
 	
PO:
Adults:
• 400 mg once daily
  ○ Max daily dose: 400 mg/day
	Infection Control:
	
	PO:
	Pediatrics:
	
	<15yrs old:
	• 10 mg/kg/day PO
	  ○ Max daily dose: 400 mg/day
	
	>15yrs old:
	• 400 mg once daily
	  ○ Max daily dose: 400 mg/day

NALOXONE

♀C, **Lactation ?**(Caution)

Trade Name: **Narcan**

Class / Mechanism of Action

Antidote, Opioid Antagonist

Competes and displaces opioids at opioid receptor sites, reversing narcotic effects.

Indications

Labeled Indications: Reversal of opioid drug effects, including respiratory depression

Contraindications

- Hypersensitivity to naloxone or any component of the formulation

Adverse Reactions / Precautions

- When correcting for respiratory depression in a postoperative (intubated patient), carefully titrate the dose to reverse hypoventilation; do not fully awaken patient or reverse analgesic effect.
- Recurrence of respiratory depression is possible continue to watch for respiratory depression until patient hand-off.
- May cause narcotic withdrawal effects

Dose and Administration:

ADULT

Opioid overdose (with standard ACS protocols):

IV, IM, SubQ:

- **0.4-2 mg**; may dose every 2-3 minutes if needed;
  - If no response after 10 mg total, look for other cause of respiratory depression.
  - Following reversal, may need to readminister after 20-60 minutes.

Reversal of respiratory depression with therapeutic opioid doses:

IV, IM, SubQ:

- **0.1-0.4 mg** titrated to adequate respiratory rate. If not improved after 0.8 mg total, look for other cause of respiratory depression.

PEDIATRIC Always Reference BROSELOW Tape

Opioid overdose (with standard PALS protocols):

IV, IM, SubQ:

- <5 years or ≤20 kg (unlabeled dose): **0.1 mg/kg/dose** (maximum dose: 2 mg); repeat every 2-3 minutes PRN
- ≥5 years or >20 kg: Adult Dosing

Reversal of respiratory depression with therapeutic opioid doses:

IV, IM, SubQ:

- **0.001-0.015 mg/kg/dose**; repeat as needed.

NIFEDIPINE

♀C, **Lactation Yes**(Not Recommended) Trade Name: **Procardia**

Class / Mechanism of Action

Antianginal Agent, Calcium Channel Blocker

Inhibits movement of calcium ion across cell membranes of smooth muscle and myocardium resulting in relaxation of coronary vascular smooth muscle and vasodilation as well as reduced peripheral vascular resistance (reducing blood pressure).

Indications

Labeled Indications: Chronic stable or vasospastic angina

Unlabeled: Prevention and treatment of high altitude pulmonary edema

Contraindications

- Hypersensitivity to nifedipine or any component of the formulation
- Cardiogenic Shock
- Acute MI

Adverse Reactions / Precautions

- Symptomatic hypotension:
- Bradycardia, nausea

Dose and Administration:	**ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
	High altitude pulmonary edema (unlabeled use): PO: • **10 mg** every 4-6 hours **Pulmonary hypertension** (unlabeled use) PO: • **30 mg** (Extended Release) twice daily; may increase cautiously to 120-240 mg/day **Note:** Do not use for acute anginal episodes; may precipitate myocardial infarction	**High altitude pulmonary edema** (Not FDA approved for use in children) (unlabeled use): PO: • Immediate release: **0.5 mg/kg/dose** (maximum: 20 mg/dose) every 8 hours **Note:** Treatment is needed only necessary if response to oxygen and/or descent is poor.

NITROGLYCERIN

♀C, **Lactation ?**(Caution) Trade Name: **NitroMist/Nitrostat**

Class / Mechanism of Action

Antianginal agent, Vasodialator

Induces smooth muscle relaxation and vasodilation of peripheral veins and arteries and coronary arteries thus improving collateral blood flow to ischemic regions of the myocardium. Reduces cardiac oxygen demand by decreasing preload. Onset of action: Sublingual tablet and spray, 1-3 minutes. Duration: 25 minutes

Indications

Labeled Indications: Treatment or prevention of angina pectoris

Contraindications

- Hypersensitivity to nitrates or any component of the formulation
- Use with phosphodiesterase-5 inhibitors (Sildenafil, Levitra, Cialis) in previous 48hrs
- Increased intracranial pressure
- Hypotension (SBP <90mmHg or >30mmHg below baseline), Bradycardia <50bpm, Tachycardia without heart failure (>100bpm), and Right ventricular infarction.

Adverse Reactions / Precautions

- **IV/IO access should be placed and SBP should be > 110.**
  - **Use cautiously in cases of chest pain unless inferior wall / right-ventricular MI can be ruled-out by ECG prior to administration**
- Can cause severe hypotension with associated paradoxical bradycardia and increased angina
- Use with caution in volume depleted patients
- Do not use for inferior wall MI and suspected right ventricular involvement

Dose and Administration:

ADULT

Angina/coronary artery disease:

PO:

- Sublingual: **0.4 mg** every 5 minutes for maximum of 3 doses in 15 minutes
- Translingual: **1 spray** (0.4mg per spray) onto or under tongue every 3-5 minutes for maximum of 3 doses in 15 minutes

CHF related Respiratory Distress:

PO:

- Sublingual: **0.4 mg** every 5 minutes for maximum of 3 doses in 15 minutes as long as SBP>90

IV Drip: (Only used at written direction of referring provider or consultation with medical director)

- Start at **10 mcg/min**, titrate up or down to:
  - 10% reduction in MAP if normotensive
  - 30% reduction in MAP if hypertensive.
  - Max dose: 400mcg/minute)

PEDIATRIC Always Reference BROSELOW Tape

Not indicated in most children, even with heart failure, as their heart failure is not usually due to coronary artery disease. Could cause significant problems in those with depressed myocardial function. Consult Medical Direction (if able) before use in Pediatrics.

CHF related Respiratory Distress:

PO:

- **0.4mg** q 5min if SBP > 70 + 2 x Age

CHF or Cardiogenic Shock:

IV Drip:

- Children: **0.25 - 0.5 mcg/kg/min**; titrate by 1 mcg/kg/min q 15-20 min as tolerated (Typical dose=1-5mcg/kg/min)(Max 10mcg/kg/min)
- Adolescents: **5-10 mcg/min** (not per kg) (max 200 mcg/min)

NOREPINEPHRINE

♀C, **Lactation? (**Caution)

Trade Name: **Levophed**

Class / Mechanism of Action

Alpha and Beta Agonist

Stimulates beta$_1$ and alpha adrenergic receptors: increases contractility, heart rate, and vasoconstriction. Increases systemic blood pressure and coronary blood flow. Effects on vasoconstriction (alpha receptors) are greater than inotropic (beta receptors). Onset of action: IV very rapid. Duration: 1-2 minutes

Indications

Labeled Indications: Treatment of shock persisting after adequate fluid volume replacement; severe hypotension.

ALS 2020: Severe cardiogenic shock and hemodynamically significant hypotension (SBP <70mmHg) with low total peripheral resistance. Agent of last resort for management of ischemic heart disease and shock.

Contraindications

- Hypersensitivity to norepinephrine, bisulfites or any component of the formulation
- Hypotension from hypovolemia except as an emergency measure to maintain coronary and cerebral perfusion until volume can be replaced

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Strong Vesicant; ensure proper catheter placement and avoid extravasation, use a large vein (preferably a central line) and avoid leg veins.
- Assure adequate circulatory volume to minimize need for vasoconstrictors. Monitor BP closely, avoid hypertension and adjust infusion rate as needed.

Dose and Administration:

ADULT

Hypotension/shock:

IV: Administer as continuous infusion with infusion pump. Do not use in same line as sodium bicarbonate. It will inactivate norepinephrine.

- Initial: **2-20 mcg/minute**; titrate to SBP goal.
  - Maintenance: **2-4 mcg/minute**

Post ROSC Hypotension:

- Initial: **0.1-0.5 mcg/kg/minute** titrate to effect.

If unable to maintain MAP >60mmHg, add **Epinephrine** infusion.

Use in Burn Patient:

For Burn patients, norepinephrine is only used when target MAP (≥55) and UOP (≥30mL/hr) fail to be reached with fluid resuscitation alone. Its sequence of use follows administration of **Vasopressin.**

(See infusion chart next page for mix and dosage information)

PEDIATRIC

Hypotension/shock:

IV: Continuous infusion

- Initial: **0.05-0.1 mcg/kg/minute**; titrate to effect
  - Max dose: 2 mcg/kg/minute

NOREPINEPHRINE (LEVOPHED)					
Dosing Range: 2-20mcg/min (120-1200mcg/hr)					
MIX 4 mg/500 mL CONCENTRATION 8 mcg/mL					
Dose	Rate	Micro (60 gtt/mL)	Macro		
			20 gtt/mL	15 gtt/mL	10 gtt/mL

Macro-Drip (20gtt/ml) or Micro-Drip is set of choice for this infusion					
Start at lowest dose and increase rate by 0.5mcg/min every 2 minutes PRN to target MAP >60mmHg					

ONDANSETRON

♀B, **Lactation?**(Caution) Trade Name: **Zofran**

Class / Mechanism of Action

Antiemetic
Blocks serotonin, peripherally on vagus nerve terminals and centrally. Onset of action is 5-30 minutes dependent on route.

Indications

Labeled Indications: Prevention of postoperative nausea and vomiting
Unlabeled: Hyperemesis gravidarum (severe or refractory)

Contraindications

- Hypersensitivity to ondansetron or any component of the formulation

Adverse Reactions / Precautions

- Dose dependent QT interval prolongation occurs and IV doses >16mg are not recommended.
  - In most patients, QT changes are not clinically relevant; however, if used with other medications that prolong QT intervals (antiarrhythmics) or in those at risk for QT prolongation, arrhythmia can occur. Torsades de points has been reported.

Dose and Administration:

ADULT

Nausea and Vomiting:
IV/IO/IM/PO

- **4-8 mg**

Treatment of severe or refractory hyperemesis gravidum (unlabeled use):
IV:

- **8 mg** administered over 15 minutes every 12 hours

PEDIATRIC Always Reference BROSELOW Tape

Nausea and Vomiting (Children 1 month to 12 years):
IV:

- ≤40 kg**: 0.1 mg/kg** as a single dose over 2-5 minutes
- >40 kg**: 4 mg** as a single dose over 2-5 Minutes

PHENYLEPHRINE ♀C, Lactation?(Caution) Trade Name: **Neosynephrine**

Class / Mechanism of Action

Alpha Adrenergic Agonist

Potent, direct acting alpha adrenergic agonist with virtually no beta adrenergic activity; causes systemic arterial vasoconstriction.

Onset of action IV: Immediate, Duration: approximately 15-20 minutes.

Indications

Labeled Indications: Treatment of hypotension, vascular failure in shock

Contraindications

- Hypersensitivity to phenylephrine or any component of the formulation
- Ventricular Tachycardia and Hypertension
- Bradycardia

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Not recommended for routine use in the treatment of septic shock
- Reflexive Bradycardia. Assure adequate circulatory volume to minimize need for vasoconstrictors. Monitor BP closely, avoid hypertension and adjust infusion rate as needed.
- Vesicant: Avoid extravasation, will cause tissue damage/necrosis, ensure proper needle placement

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Hypotension / Shock:

IV Push:

- **50-200 mcg/dose** q 5-10 minutes
  - Max 1000 mcg
  - Titrate to blood pressure, use as temporary support or bridge to Vasopressor drip
  - Mix 10mg phenylephrine in 100mL NS for a concentration of 100mcg/mL

IV Infusion:

- **40 - 200 mcg/min;** titrate to MAP > 60 mm Hg.
  - To titrate, increase rate by 10 mcg/min every 2 minutes.
  - Maximum dose is 200 mcg/min.
  - Mix 10mg phenylephrine in 250mL D5W/NS for a concentration for 40mcg/mL

If unable to maintain MAP >60mmHg, add Epinephrine infusion.

Hypotension / Shock:

IV Push:

- **5-20 mcg/kg/dose** every 10-15 minutes as needed

IV Infusion:

- **0.1-0.5 mcg/kg/minute**

Note: Almost never used in pediatric shock. Isolated increased afterload usually causes significant problems in this population. Use with caution and contact Medical Direction if able.

PRALIDOXIME CHLORIDE

♀C, **Lactation?**(Caution) Trade: **2-Pam Chloride**

Class / Mechanism of Action

Antidote for organophosphate anticholinesterase poisoning
Peak plasma concentration following IM dose is reached in approximately 30 minutes

Indications

Labeled Indications:

- Organophosphate Pesticide Poisoning: Used with Atropine to reverse muscle paralysis
- Chemical Warfare Agent Poisoning: Used with Atropine for treatment of nerve agent (e.g., sarin, soman, tabun, VX [methylphosphonothioic acid])

Contraindications

- None in emergency setting

Adverse Reactions / Precautions

- Not effective in exposure to phosphorus, inorganic phosphates, or organophosphates that do not possess anticholinesterase activity.
- Consider cautions and adverse reactions of Atropine when using together
- Monitor BP and cardiac rhythm

Dose and Administration:

Pesticide Poisoning:

Mild symptoms: Miosis or blurred vision, tearing, runny nose, hypersalivation or drooling, wheezing, muscle fasciculations, nausea/vomiting.
Severe symptoms: behavioral changes, severe breathing difficulty, severe respiratory secretions, severe muscle twitching, involuntary defecation or urination, seizures, unconsciousness.

Chemical Warfare Agent Poisoning:

Mild to moderate symptoms: localized sweating, muscle fasciculations, nausea, vomiting, weakness, and/or dyspnea.
Severe symptoms: apnea, flaccid paralysis, seizures, and/or unconsciousness.

DOSING:

Auto-injector: IM into anterolateral aspect of thigh and hold in place for 10 seconds.

- Pralidoxime chloride auto-injector single dose 600mg: (administer after **Atropine**). Repeat injections if symptoms remain after 15min. Repeat again if not resolved after 2nd 15min.
- DuoDote®, ATNAA: For ≥2 mild symptoms, inject single dose. If severe symptoms develop, inject 2 additional doses in rapid succession.
- DuoDote®, ATNAA: For severe symptoms, utilize 3 auto-injectors (total dose: atropine 6.3 mg and pralidoxime chloride 1800 mg) in rapid succession.

Note: DuoDote® and ATNAA auto-syringe provides a sequential single IM dose of atropine (2.1mg) and pralidoxime chloride (600mg) through one needle.

Chemical Warfare Agent Poisoning:

Pralidoxime (2-PAM) Drip Protocol 8-10mg/kg/hr
*given after 1800mg IM Injection (3 ATNAAs) if symptoms persist.

1. Reconstitute 1 gram 2-PAM with 20mL of sterile water
2. Add 10mL 2Pam (500mg) to 100 mL Bag of NS and infuse over 5 minutes
3. Prepare continuous infusion by mixing 1 gram (20mL reconstituted) in 100mL bag of NS which will provide a 10mg/mL solution. Can also prepare 10 grams in 1L NS for a 10mg/mL solution.
4. Begin continuous infusion at 10mg/kg/hr.

Chemical Warfare Agent Poisoning: Organophosphate Anticholinesterase Nerve Agents:

IM:

- Children 0–10 years of age and adolescents >10 years of age who present with mild/moderate symptoms: 15 mg/kg.
- Children 0–10 years of age and adolescents >10 years of age who present with severe symptoms: 25 mg/kg.
- Children and Adolescents ≥40 kg dose as adult

PROCAINAMIDE

♀C, **Lactation?**(Not Recommended) Trade Name: **Procanbid**

Class / Mechanism of Action

Antiarrhythmic Agent, Class Ia

Decreases myocardial excitability & conduction velocity, may depress myocardial contractility by increasing the electrical stimulation threshold of ventricle, His-Purkinje system and through direct cardiac effects

Onset of action: IV: 5 minutes, IM: (**Not for emergent situations)** 10 to 30 minutes, Duration 4-6 hours

Indications

Labeled Indications: Treatment of supraventricular arrhythmias, life-threatening ventricular arrhythmias.

Unlabeled: Atrial fibrillation (preexcited); Junctional tachycardia; Stable monomorphic ventricular tachycardia.

Contraindications

- Hypersensitivity to procainamide, procaine, other ester-type local anesthetics
- complete heart block; second-degree AV block or various types of hemiblock
- SLE (Systemic lupus erythematosus)
- Torsade de pointes

Adverse Reactions / Precautions

- Lupus-like syndrome
- Hypotension
- Skin rash
- Diarrhea, dysgeusia, nausea/vomiting

Dose and Administration:

ADULT

Ventricular arrhythmias/ Atrial fibrillation (preexcited):

Note: Dose must be individualized and titrated to patient response

- IV Loading dose: 10 to 17 mg/kg at a rate of 20 to 50 mg/minute **or** 100 mg every 5 minutes;
- Must dilute prior to IV administration. Dilute loading dose to a maximum concentration of 20 mg/mL; administer loading dose at a maximum rate of 50 mg/minute until:
  - Arrhythmia suppression
  - Hypotension
  - QRS widens by >50%
  - total dose 17mg/kg reached
- Maintenance infusion: 2 to 6 mg/min

PEDIATRIC Always Reference BROSELOW Tape

Ventricular arrhythmias:

Infants, Children, and Adolescents IV:

- Loading dose: 10 to 15 mg/kg over 30 to 60 minutes
  - Neonates: Administer over 60 minutes
  - Infants and Children: Administer over 30 to 60 minutes
  - Adolescents: Administer at usual infusion rate: 20 to 50 mg/minute not to exceed 50 mg/minute
- Maintenance infusion: 20 to 80 **mcg**/kg/minute; maximum daily dose: 2000 mg/24 hours

Note: Infusion rate should be decreased if QT interval becomes prolonged or patient develops heart block; discontinue the infusion if patient develops hypotension or QRS interval widens to >50% of baseline; severe hypotension can occur with rapid IV administration

PROMETHAZINE

♀C, **Lactation?**(Not Recommended) Trade Name: **Phenergan**

Class / Mechanism of Action

Phenothiazine derivative Antiemetic, Histamine H_1 Antagonist, Sedative

Blocks postsynaptic dopaminergic receptors in the brain; strong alpha adrenergic blocking effect and depresses release of hypothalamic and hypophyseal hormones; reduces stimuli to the reticular system

Onset of action IV: 5 minutes, Duration 4-6 hours

Indications

Labeled Indications: Symptomatic treatment for allergic conditions; antiemetic; motion sickness; sedative; adjunct to postoperative analgesia and anesthesia

Unlabeled: Treatment of nausea and vomiting of pregnancy

Contraindications

- Hypersensitivity to promethazine, phenothiazine allergy, or any component of the formulation
- Coma
- Children <2 years old
- Intra-arterial and SubQ administration

Adverse Reactions / Precautions

- May cause Bradycardia, hyper-/hypotension, nonspecific QT changes, orthostatic hypotension, tachycardia: Life threatening arrhythmias have occurred with normal dosage
- May cause extrapyramidal symptoms (pseudoparkinsonism, acute dystonic reactions, akathisia, etc.)
- Avoid use in severe respiratory disease (asthma, COPD), and in patients using other sedatives or depressants: may lead to respiratory depression
- **Vesicant**: can cause severe tissue injury regardless of route of delivery
  - Deep IM injection; or IV in line. Slow IVP over 1 minute
  - For IV, ensure proper needle/catheter venous placement; avoid extravasation

Dose and Administration: ADULT

Antiemetic:

IV push over >1 minute

- **12.5 mg, not to exceed 25 mg**
  - May repeat 12.5mg once after 10 minutes if first dose ineffective
  - Subsequent dose of 25mg may be given every 4 hours
  - Can dilute with 10-20mL of NS

Sedation, analgesia/hypnotic adjunct:

IM, IV:

- **25-50 mg** in combination with analgesic or hypnotic (at reduced dosage)

Allergic conditions (including allergic reactions to blood or plasma):

IM, IV:

- **25 mg**, may repeat in 2 hours when necessary

PEDIATRIC Always Reference BROSELOW Tape

Antiemetic:

IM, IV:

- Children ≥2 years: **0.25 mg/kg** 4-6 times/day as needed (maximum: 12.5 mg/dose)

Preoperative analgesia/hypnotic adjunct:

IM, IV:

- Children ≥2 years: **1.1 mg/kg** in combination with an analgesic or hypnotic (at reduced dosage) and with an atropine like agent (at appropriate dosage).

Note: Promethazine dosage should not exceed half of suggested adult dosage.

PROPOFOL

♀B, **Lactation Yes**(Not Recommended) Trade Name: **Diprivan**

Class / Mechanism of Action

General Anesthetic

Lipophilic intravenous general anesthetic.

Onset of action IV bolus: 9-51 seconds (average 30 seconds), Duration is dose and rate dependent: 3-10 minutes, prolonged with continued doses

Indications

Labeled Indications: Induction of anesthesia in patients ≥3 years of age; maintenance of anesthesia in patients >2 months of age; sedation in intubated, mechanically-ventilated ICU patients

Contraindications

- Hypersensitivity to propofol or any component of the formulation
- Allergy to eggs, egg products, soybeans, soy products, and peanuts.

Adverse Reactions / Precautions

- May cause Hypotension especially in hypovolemic patients or if bolus dosing is used.
  - Hypotension may result in reduction of MAP exceeding 30%
    - Head Injury patients or those with suspected / known increased intracranial pressure are at increased risk of decreased cerebral perfusion pressure.
- Do not use in pre-hospital trauma environment or in transfer patients unless directed by medical director or provided written orders by referring provider.
- No Analgesic properties. Must supplement with analgesic agents.

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

ADULT

Sedation/ RSI:

IV Push:

- **1-2.5 mg/kg** every 5-10min PRN.

Maintenance of general anesthesia:

IV Infusion:

- **10-75 mcg/kg/min** via infusion pump or Dial-a-Drip. Titrate to minimum effective dose. **(See infusion chart next page)**
  - MAX DOSE: 100 mcg/kg/min.
- Use of Dial-a-Drip tubing in the absence of an infusion pump will increase accuracy of infusion dosage.

Note: Wait 3-5 minutes between dosage changes to clinically assess drug effects. Smaller doses are required when used with opioids.

PEDIATRIC

Sedation/ RSI:

IV Push:

- **1-2.5 mg/kg** every 5-10min PRN.

Maintenance of general anesthesia,

IV Infusion:

Healthy children 2 months to 16 years:

- **125-300 mcg/kg/minute** (or 7.5-18 mg/kg/hour)

PROPOFOL (DIPRIVAN)						
Dosing Range: 10-75mcg/kg/min (600-3000mcg/kg/hr)						
MIX 500 mg/50 mL CONCENTRATION 10 mg/mL
